If Graft messages were not used, then the member waiting for pruned off traffic would have to wait up to 3 minutes for the periodic re-flooding to occur to begin receiving multicast traffic again. By using Grafts, the Prune can be reversed much faster than waiting for periodic re-flooding to begin receiving multicast traffic again.

Examples To configure PIM-DM to send a maximum of 10 Graft message retries, use the following commands:

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ip pim max-graft-retries 10
```

To configure PIM-DM to send Graft message retries forever, which is the default behavior, use the following commands:

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# no ip pim max-graft-retries
```

Validation Commands

show ip mroute
show ip pim dense-mode mroute
show running-config

ip pim neighbor-filter (PIM-DM)

Enables filtering of neighbors on the VLAN interface. When configuring a neighbor filter, PIM-DM will either not establish adjacency with the neighbor, or terminate adjacency with the existing neighbors if denied by the filtering access list.

Use the no variant of this command to disable this function.

Syntax

```
ip pim neighbor-filter [<number>|<accesslist>]
no ip pim neighbor-filter [<number>|<accesslist>]
```

Parameter	Description
<number>	*<1-99>* Standard IP access list number.
<accesslist>	IP access list name.

Default By default, there is no filtering.

Mode Interface Configuration for a VLAN interface.

Example

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ip pim neighbor-filter 14
```

ip pim propagation-delay

This command configures the PIM propagation-delay value. The PIM propagation-delay is the expected delay in the transfer of PIM messages across the VLAN interface that it is attached to.

Use the no variant of this command to return the propagation-delay to the default (1000 milliseconds).

Syntax

```
ip pim propagation-delay <delay>
no ip pim propagation-delay
```

Parameter	Description
<delay>	*<1000-5000>* The value in milliseconds. The default is 1000 milliseconds.

Default The propagation-delay is set to 1000 milliseconds by default.

Mode Interface Configuration for a VLAN interface.

Examples

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ip pim propagation-delay 2000

awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# no ip pim propagation-delay
```

ip pim state-refresh origination-interval

This command configures a PIM state-refresh origination-interval value. The origination interval is the number of seconds between PIM state refresh control messages. The default is 60 seconds.

Use the no variant of this command to return the origination interval to the default.

Syntax

```
ip pim state-refresh origination-interval <interval>
no ip pim state-refresh origination-interval
```

Parameter	Description
<interval>	**<1-100>** The integer value in seconds (no fractional seconds accepted). The default state-refresh origination-interval value is 60.

Default The state-refresh origination-interval is set to 60 seconds by default, and is reset using negation.

Mode Interface Configuration for a VLAN interface.

Example

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ip pim state-refresh origination-interval 65
```

show debugging pim dense-mode

This command displays the status of the debugging of the system.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show debugging pim dense-mode`

Mode User Exec and Privileged Exec

Output Figure 53-2: Example output from the **show debugging pim dense-mode** command

```
PIM-DM Debugging status:
  PIM-DM VR-VRF Context debugging is off
  PIM-DM Decoder debugging is off
  PIM-DM Encoder debugging is off
  PIM-DM FSM debugging is off
  PIM-DM MRT debugging is off
  PIM-DM NHOP debugging is off
  PIM-DM NSM debugging is off
  PIM-DM VIF debugging is off
```

Related Commands debug pim dense-mode all

show ip pim dense-mode interface

This command displays the PIM-DM interface information.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip pim dense-mode interface`

Mode User Exec and Privileged Exec

Example To display information about the PIM-DM interfaces, use the command:

```
awplus# show ip pim dense-mode interface
```

Output

Figure 53-3: Example output from the **show ip pim dense-mode interface** command

```
Total configured interfaces: 100   Maximum allowed: 100
Total active interfaces:     100

Address          Interface VIFIndex Ver/   Nbr
                                    Mode   Count
10.1.100.4       vlan100   4        v2/D   0
10.2.101.10      vlan1001  5        v2/D   0
10.2.102.10      vlan1002  6        v2/D   0
10.2.103.10      vlan1003  7        v2/D   0
10.2.104.10      vlan1004  8        v2/D   0
10.2.105.10      vlan1005  9        v2/D   0
10.2.106.10      vlan1006  10       v2/D   0
10.2.107.10      vlan1007  11       v2/D   0
```

1. Only the top entries output by this command are shown in this example.

Table 53-1: Parameters in the output of the **show ip pim dense-mode interface** command

Parameter	Description
`Total configured interfaces`	The number of configured PIM Dense Mode interfaces.
`Maximum allowed`	The maximum number of PIM Dense Mode interfaces that can be configured.
`Total active interfaces`	The number of active PIM Dense Mode interfaces.
`Address`	Primary PIM-DM address.
`Interface`	Name of the PIM-DM interface.
`VIF Index`	The Virtual Interface index of the VLAN.
`Ver/Mode`	PIM version/Dense mode.
`Nbr Count`	Neighbor count of the PIM-DM interface.

Related Commands ip pim dense-mode
show ip pim dense-mode neighbor

show ip pim dense-mode interface detail

This command displays detailed information on a PIM-DM interface.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip pim dense-mode interface detail`

Mode User Exec and Privileged Exec

Example

```
awplus# show ip pim dense-mode interface detail
```

Output Figure 53-4: Example output from the **show ip pim dense-mode interface detail** command

```
vlan2 (vif-id: 0):
  Address 192.168.1.53/24
  Hello period 30 seconds, Next Hello in 30 seconds
  Neighbors:
    192.168.1.152/32
    192.168.1.149/32
vlan3 (vif-id: 2):
  Address 192.168.10.53/24
  Hello period 30 seconds, Next Hello in 8 seconds
  Neighbors: none
```

show ip pim dense-mode mroute

This command displays the IP PIM-DM multicast routing table.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip pim dense-mode mroute`

Mode User Exec and Privileged Exec

Example

```
awplus# show ip pim dense-mode mroute
```

Output Figure 53-5: Example output from the **show ip pim dense-mode mroute** command

```
PIM-DM Multicast Routing Table
(192.168.10.52, 224.1.1.1)
  Source directly connected on vlan3
  State-Refresh Originator State: Originator
  Upstream IF: vlan3, State: Forwarding
  Downstream IF List:
    vlan2, in 'olist':
      Downstream State: NoInfo
      Assert State: NoInfo
```

show ip pim dense-mode neighbor

This command displays PIM-DM neighbor information.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip pim dense-mode neighbor`

Mode User Exec and Privileged Exec

Usage The total number of PIM-DM neighbors is restricted to 500 PIM-DM neighbors.

When the 500 PIM-DM neighbor limit is reached, as a result of receiving hello packets from new PIM-DM neighbors, a log entry will be issued to the log file in the below format:

```
<date> <time> <facility>.<severity> <program[<pid>]>: <message>
-------------------------------------------------------------------
2008 Dec 10 00:58:39 user.err x900 PIM-DM[1150]: [VIF] Nbr
Create: Cannot create more than 500 neighbours - ignoring
neighbour 100.0.1.247/32 on vlan100
```

Example

```
awplus# show ip pim dense-mode neighbor
```

Output Figure 53-6: Example output from the **show ip pim dense-mode neighbor** command

```
Total number of neighbors: 500
Neighbor-Address  Interface          Uptime/Expires    Ver
192.168.1.152     vlan2                17:15:42/00:01:28 v2
192.168.1.149     vlan2                17:15:34/00:01:34 v2
```

show ip pim dense-mode neighbor detail

This command displays detailed PIM-DM neighbor information.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip pim dense-mode neighbor detail`

Mode User Exec and Privileged Exec

Example

```
awplus# show ip pim dense-mode neighbor detail
```

Output Figure 53-7: Example output from the **show ip pim dense-mode neighbor detail** command

```
Neighbor 192.168.1.152 (vlan2)
 Up since 17:16:20, Expires in 00:01:20
Neighbor 192.168.1.149 (vlan2)
 Up since 17:16:12, Expires in 00:01:26
```

show ip pim dense-mode nexthop

This command displays the nexthop information as used by PIM-DM. In the context of PIM-DM, the term 'nexthop' refers to the nexthop router on the path back to the source address of a multicast stream.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip pim dense-mode nexthop`

Mode User Exec and Privileged Exec

Example

```
awplus# show ip pim dense-mode nexthop
```

Output Figure 53-8: Example output from the **show ip pim dense-mode neighbor nexthop** command

```
Destination      Nexthop   Nexthop         Nexthop          Metric Pref
                 Num       Addr            Interface
192.168.10.52    1         0.0.0.0         vlan2            3      1
```

Table 53-2: Parameters in the output of the **show ip pim dense-mode neighbor nexthop** command

Parameter	Description
`Destination`	Destination address for which PIM-DM requires nexthop information.
`Nexthop Num`	Number of nexthops to the destination. PIM can only use one nexthop.
`Nexthop Addr`	Address of the current nexthop gateway.
`Nexthop Interface`	Name of the nexthop interface.
`Metric`	Metric of the route towards the destination.
`Preference`	Preference of the route towards the destination.

undebug all pim dense-mode

Use this command from the Global Configuration mode to disable all PIM-DM debugging.

Syntax `undebug all pim dense-mode`

Mode Global Configuration

Example

```
awplus# configure terminal
awplus(config)# undebug all pim dense-mode
```

Introduction

Multicast Listener Discovery (MLD) is used to exchange membership status information between IPv6 routers that support multicasting and members of multicast groups on a network segment. Host membership in a multicast group is reported by individual member hosts, and membership status is periodically polled by multicast routers. For a general overview of multicasting, see Chapter 47, Multicast Introduction and Commands.

MLD is defined in RFC 2710, "Multicast Listener Discovery (MLD) for IPv6."

MLD Snooping

MLD Snooping is a feature whereby a Layer 2 switch listens to or "snoops" the MLD messages passing through the switch or from member hosts and multicast routers. The purpose of MLD Snooping is to provide efficient Layer 2 multicast forwarding, by sending only to hosts that have expressed an interest in receiving the multicast data.

Hosts express an interest in receiving multicast data for a given multicast group by sending an MLD join message. Without MLD Snooping, if one host expresses an interest in getting multicast data for a given group, by sending an MLD join for the multicast group, then all hosts connected to the same VLAN will also receive the multicast data. This wastes bandwidth on the switch ports connected to the host that are not interested in receiving the multicast data. Snooping takes note of exactly which ports have received joins for a given group, and send that group only to those ports.

MLD Snooping is enabled by default globally for the switch. It can be enabled and disabled on a per-VLAN basis.

MLD Snooping makes a distinction between Member ports, which are ports connected to members hosts, and Router ports, which are ports connected to, or directed towards, a Layer 3 router or a Layer 3 switch.

Command List

This chapter provides an alphabetical reference of configuration, clear, and show commands related to MLD Snooping.

clear ipv6 mld

Use this command to clear all MLD local memberships on all interfaces.

Syntax `clear ipv6 mld`

Mode Privileged Exec

Usage This command applies to groups learned by MLD Snooping.

Example

```
awplus# clear ipv6 mld
```

Related Commands clear ipv6 mld group
clear ipv6 mld interface

clear ipv6 mld group

Use this command to clear MLD specific local-membership(s) on all interfaces, for a particular group.

Syntax `clear ipv6 mld group {*|<ipv6-address>}`

Parameter	Description
*	Clears all groups on all interfaces. This is an alias to the clear ipv6 mld command.
<ipv6-address>	Specify the group address for which MLD local-memberships are to be cleared from all interfaces. Specify the IPv6 multicast group address in the format in the format X:X::X:X.

Mode Privileged Exec

Usage This command applies to groups learned by MLD Snooping.

Example

```
awplus# clear ipv6 mld group *
```

Related Commands clear ipv6 mld
clear ipv6 mld interface

clear ipv6 mld interface

Use this command to clear MLD interface entries.

Syntax `clear ipv6 mld interface <interface>`

Parameter	Description
<interface>	Specifies name of the interface; all groups learned from this interface are deleted.

Mode Privileged Exec

Usage This command applies to interfaces configured for MLD Snooping.

Example

```
awplus# clear ipv6 mld interface vlan2
```

Related Commands clear ipv6 mld
clear ipv6 mld group

debug mld

Use this command to enable all MLD debugging modes, or a specific MLD debugging mode.

Use the no variant of this command to disable all MLD debugging modes, or a specific MLD debugging mode.

Syntax

```
debug mld {all|decode|encode|events|fsm|tib}
no debug mld {all|decode|encode|events|fsm|tib}
```

Parameter	Description
`all`	Debug all MLD.
`decode`	Debug MLD decoding.
`encode`	Debug MLD encoding.
`events`	Debug MLD events.
`fsm`	Debug MLD Finite State Machine (FSM).
`tib`	Debug MLD Tree Information Base (TIB).

Mode Privileged Exec and Global Configuration

Examples

```
awplus# configure terminal
awplus(config)# debug mld all

awplus# configure terminal
awplus(config)# debug mld decode

awplus# configure terminal
awplus(config)# debug mld encode

awplus# configure terminal
awplus(config)# debug mld events
```

ipv6 mld access-group

Use this command to control the multicast local-membership groups learned on an interface.

Use the no variant of this command to disable this access control.

Syntax

```
ipv6 mld access-group <access-list-name>
no ipv6 mld access-group
```

Parameter	Description
<access-list-name>	Standard IPv6 access-list name.

Default No access list is configured by default.

Mode Interface Configuration for a specified VLAN interface or a range of VLAN interfaces.

Usage This command applies to groups learned by MLD Snooping.

Example In the following example, `vlan2` will only accept MLD joins for groups in the range `ff1e:0db8:0001::/64`:

```
awplus# configure terminal
awplus(config)# ipv6 access-list standard group1 permit
ff1e:0db8:0001::/64
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld access-group group1
```

In the following example, `vlan2-vlan4` will only accept MLD joins for groups in the range `ff1e:0db8:0001::/64`:

```
awplus# configure terminal
awplus(config)# ipv6 access-list standard group1 permit
ff1e:0db8:0001::/64
awplus(config)# interface vlan2-vlan4
awplus(config-if)# ipv6 mld access-group group1
```

ipv6 mld limit

Use this command to configure a limit on the maximum number of group memberships that may be learned. The limit may be set for the switch as a whole, or for a specific interface.

Once the specified group membership limit is reached, all further local-memberships will be ignored.

Optionally, an exception access-list can be configured to specify the group-address(es) that are exempted from being subject to the limit.

Use the no variant of this command to unset the limit and any specified exception access-list.

Syntax

```
ipv6 mld limit <limitvalue> [except <access-list-name>]
no ipv6 mld limit
```

Parameter	Description
<limitvalue>	<2-512> Maximum number of group membership states.
<access-list-name>	Standard IPv6 access-list name that defines multicast groups which are exempted from being subject to the configured limit.

Default The default limit, which is reset by the no variant of this command, is the same as maximum number of group membership entries that can be learned with the ipv6 mld limit command.

The default limit of group membership entries that can be learned is 512 entries.

Mode Global Configuration and Interface Configuration for a specified VLAN interface or a range of VLAN interfaces.

Usage This command applies to interfaces learned by MLD Snooping.

If this command is issued on multiple VLAN interfaces, the limits apply individually to each of those interfaces.

Examples The following example configures an MLD limit of 100 group-memberships across all VLAN interfaces on which MLD is enabled, and excludes groups in the range `ff1e:0db8:0001::/64` from this limitation:

```
awplus# configure terminal
awplus(config)# ipv6 access-list standard v6grp permit
ff1e:0db8:0001::/64
awplus(config)# ipv6 mld limit 100 except v6grp
```

The following example configures an MLD limit of 100 group-membership states on `vlan2`:

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld limit 100
```

The following example configures an MLD limit of 100 group-membership states on `vlan2-vlan4`:

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config-if)# ipv6 mld limit 100
```

Related Commands show ipv6 mld groups

ipv6 mld snooping

Use this command to enable MLD Snooping. When this command is issued in the Global Configuration mode, MLD Snooping is enabled globally for the switch. When this command is issued in Interface mode for a VLAN then MLD Snooping is enabled for the specified VLAN. Note that MLD Snooping is enabled on the VLAN only if it is enabled globally and on the VLAN.

Use the no variant of this command to globally disable MLD Snooping in Global Configuration mode, or for the specified VLAN interface in Interface mode.

Syntax

```
ipv6 mld snooping
no ipv6 mld snooping
```

Default By default, MLD Snooping is enabled both globally and on all VLANs.

Mode Global Configuration and Interface Configuration for a specified VLAN interface or a range of VLANs.

Usage For MLD Snooping to operate on particular VLAN interfaces, it must be enabled both globally by using this command in Global Configuration mode, and on individual VLAN interfaces by using this command in Interface Configuration mode (Both are enabled by default).

Examples To configure MLD Snooping on `vlan2`, enter the following commands:

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld snooping
```

To configure MLD Snooping on `vlan2-vlan4`, enter the following commands:

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config-if)# ipv6 mld snooping
```

To disable MLD Snooping for `vlan2`, enter the following commands:

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config)# no ipv6 mld snooping
```

To disable MLD Snooping for `vlan2-vlan4`, enter the following commands:

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config)# no ipv6 mld snooping
```

To configure MLD Snooping globally for the switch, enter the following commands:

```
awplus# configure terminal
awplus(config)# ipv6 mld snooping
```

To disable MLD Snooping globally for the switch, enter the following commands:

```
awplus# configure terminal
awplus(config)# no ipv6 mld snooping
```

ipv6 mld snooping fast-leave

Use this command to enable MLD Snooping fast-leave processing. Fast-leave processing is analogous to immediate-leave processing; the MLD group-membership is removed as soon as an MLD leave group message is received, without sending out a group-specific query.

Use the no variant of this command to disable fast-leave processing.

Syntax

```
ipv6 mld snooping fast-leave
no ipv6 mld snooping fast-leave
```

Default MLD Snooping fast-leave processing is disabled.

Mode Interface Configuration for a specified VLAN interface or a range of VLAN interfaces.

Usage This MLD Snooping command can only be configured on VLAN interfaces.

Example This example shows how to enable fast-leave processing on `vlan2`.

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld snooping fast-leave
```

This example shows how to enable fast-leave processing on `vlan2-vlan4`.

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config-if)# ipv6 mld snooping fast-leave
```

ipv6 mld snooping mrouter

Use this command to statically configure the specified port as a Multicast Router interface for MLD Snooping within the specified VLAN.

Use the no variant of this command to remove the static configuration of the interface as a Multicast Router interface.

Syntax

```
ipv6 mld snooping mrouter interface <port>
no ipv6 mld snooping mrouter interface <port>
```

Parameter	Description
<port>	Specify the name of the port.

Mode Interface Configuration for a specified VLAN interface or a range of VLAN interfaces.

Usage This MLD Snooping command statically configures a switch port as a Multicast Router interface.

Example This example shows how to specify the next-hop interface to the multicast router for `vlan2`.

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld snooping mrouter interface
port1.0.5
```

This example shows how to specify the next-hop interface to the multicast router for `vlan2-vlan4`.

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config-if)# ipv6 mld snooping mrouter interface
port1.0.5
```

ipv6 mld snooping report-suppression

Use this command to enable report suppression from hosts for Multicast Listener Discovery version 1 (MLDv1) on a VLAN in interface configuration mode.

Use the no variant of this command to disable report suppression on a VLAN in interface configuration mode.

Syntax

```
ipv6 mld snooping report-suppression
no ipv6 mld snooping report-suppression
```

Default Report suppression does not apply to MLDv2, and is turned on by default for MLDv1 reports.

Mode Interface Configuration for a specified VLAN interface or a range of VLAN interfaces.

Usage This MLD Snooping command can only be configured on VLAN interfaces.

MLDv1 Snooping maybe configured to suppress reports from hosts. When a querier sends a query, only the first report for particular set of group(s) from a host will be forwarded to the querier by the MLD Snooping switch. Similar reports (to the same set of groups) from other hosts, which would not change group memberships in the querier, will be suppressed by the MLD Snooping switch to prevent 'flooding' of query responses.

Examples This example shows how to enable report suppression for MLD reports on `vlan2`.

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld snooping report-suppression
```

This example shows how to enable report suppression for MLD reports on `vlan2-vlan4`.

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config-if)# ipv6 mld snooping report-suppression
```

This example shows how to disable report suppression for MLD reports on `vlan2`:

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# no ipv6 mld snooping report-suppression
```

This example shows how to disable report suppression for MLD reports on `vlan2-vlan4`:

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config-if)# no ipv6 mld snooping report-suppression
```

ipv6 mld static-group

Use this command to statically configure IPv6 group membership entries on an interface. To statically add only a group membership, do not specify any parameters.

Use the no variant of this command to delete static group membership entries.

Syntax

```
ipv6 mld static-group <ipv6-group-address>
   [source <ipv6-source-address>] [interface <port>]

no ipv6 mld static-group <ipv6-group-address>
   [source <ipv6-source-address>] [interface <port>]
```

Parameter	Description
<ipv6-group-address>	Specify a standard IPv6 Multicast group address to be configured as a static group member. The IPv6 address uses the format X:X::X:X.
<ipv6-source-address>	Optional. Specify a standard IPv6 source address to be configured as a static source from where multicast packets originate. The IPv6 address uses the format X:X::X:X.
<port>	Optional. Physical interface. This parameter specifies a physical port. If this parameter is used, the static configuration is applied to just to that physical interface. If this parameter is not used, the static configuration is applied on all ports in the VLAN.

Mode Interface Configuration for a specified VLAN interface.

Usage This command applies to MLD Snooping on a VLAN interface to statically add groups and/or source records.

Example The following examples show how to statically add group and/or source records for MLD Snooping on `vlan2`:

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld static-group ff1e::10
```

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld static-group ff1e::10 source
fe80::2fd:6cff:fe1c:b
```

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld static-group ff1e::10
```

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld static-group ff1e::10 interface
port1.0.8
```

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld static-group ff1e::10 source
fe80::2fd:6cff:fe1c:b interface port1.0.8
```

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ipv6 mld static-group ff1e::10 interface
port1.0.8
```

show ipv6 mld groups

Use this command to display the multicast groups with receivers directly connected to the router, and learned through MLD.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax

```
show ipv6 mld groups [<ipv6-address> |<interface> detail]
```

Parameter	Description
<ipv6-address>	Optional. Specify Address of the multicast group in format X:X::X:X.
<interface>	Optional. Specify the Interface name for which to display local information.

Mode User Exec and Privileged Exec

Example The following command displays local-membership information for all interfaces:

```
awplus# show ipv6 mld groups
```

Output Figure 54-1: Example output from the **show ipv6 mld groups** command

```
MLD Connected Group Membership
Group Address    Interface     Uptime      Expires    Last
Reporter
ff1e::10         ge10          00:03:16    00:01:09
fe80::202:b3ff:fef0:79d8
```

show ipv6 mld interface

Use this command to display the state of MLD Snooping for a specified interface, or all interfaces.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ipv6 mld interface [<interface>]`

Parameter	Description
<interface>	Interface name.

Mode User Exec and Privileged Exec

Example The following command displays MLD interface status on all interfaces enabled for MLD:

```
awplus# show ipv6 mld interface
```

Output Figure 54-2: Example output from the **show ipv6 mld interface** command

```
Interface vlan1 (Index 2)
 MLD Enabled, Active, Querier, Version 2 (default)
 Internet address is fe80::2fd:6cff:fe1c:b
 MLD interface has 0 group-record states
 MLD activity: 0 joins, 0 leaves
 MLD query interval is 125 seconds
 MLD querier timeout is 255 seconds
 MLD max query response time is 10 seconds
 Last member query response interval is 1000 milliseconds
 Group Membership interval is 260 seconds
```

show ipv6 mld snooping mrouter

Use this command to display the multicast router interfaces, both configured and learned, in a VLAN.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ipv6 mld snooping mrouter <interface>`

Parameter	Description
<interface>	The name of the VLAN interface.

Mode User Exec and Privileged Exec

Example The following command displays the multicast router interfaces in `vlan2`:

```
awplus# show ipv6 mld snooping mrouter vlan2
```

Output Figure 54-3: Example output from the **show ipv6 mld snooping mrouter** command

```
VLAN    Interface    Static/Dynamic
2       port1.0.2
2       port1.0.3
```

show ipv6 mld snooping statistics

Use this command to display MLD Snooping statistics data.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ipv6 mld snooping statistics interface <interface>`

Parameter	Description
<interface>	The name of the VLAN interface.

Mode User Exec and Privileged Exec

Example The following command displays MLDv2 statistical information for `vlan2`:

```
awplus# show ipv6 mld snooping statistics interface vlan2
```

Output Figure 54-4: Example output from the **show ipv6 mld snooping statistics** command

```
Interface:      vlan2
Group:          ff1e::10
Uptime:         00:00:13
Group mode:     Include
Last reporter:  fe80::202:b3ff:fef0:79d8
Group source list: (R - Remote, M - SSM Mapping)
  Source Address        Uptime    v2 Exp    Fwd  Flags
  7ffe::4               00:00:13  00:04:06  Yes  R
```

Introduction

This chapter describes Access Control Lists (ACLs), and general ACL configuration information.

See Chapter 56, IPv4 Hardware Access Control List (ACL) Commands and Chapter 58, IPv6 Hardware Access Control List (ACL) Commands for detailed command information and command examples about IPv4 and IPv6 hardware ACLs that are applied directly to interfaces.

See Chapter 57, IPv4 Software Access Control List (ACL) Commands and Chapter 59, IPv6 Software Access Control List (ACL) Commands for detailed command information and command examples about IPv4 and IPv6 software ACLs as applied to Routing and Multicasting.

See all relevant Routing commands and configurations in "Layer Three, Switching and Routing" and all relevant Multicast commands and configurations in "Multicast Applications".

Overview

An Access Control List (ACL) is one filter, or a sequence of filters, that are applied to an interface to either block, pass, or when using QoS, apply priority to, packets that match the filter definitions. ACLs are used to restrict network access by hosts and devices and to limit network traffic.

An ACL contains an ordered list of filters. Each filter specifies either permit or deny and a set of conditions the packet must satisfy in order to match the filter. The meaning of permit or deny entries depends on the context in which the ACL is used - either on an inbound or an outbound interface.

When a packet is received on an interface, the switch compares fields in the packet against filters in the ACL to check whether the packet has permission to be forwarded, based on the filter properties. The first match determines whether the switch accepts or rejects the packets. If no entries match, the switch rejects the packets. If there are no restrictions, the switch forwards the packets.

Because filters in an ACL are applied sequentially and their action stops at the first match, it is very important that you apply the filters in the correct order. For example you might want to pass all traffic from VLAN 4 except for that arriving from two selected addresses A and B. Setting up a filter that first passes all traffic from VLAN 4 then denies traffic from addresses A and B will not filter out traffic from A and B if they are members VLAN 4. To ensure that the traffic from A and B is always blocked you should first apply the filter to block traffic from A and B, then apply the filter to allow all traffic from VLAN 4.

You can assign sequence numbers to filters. See "ACL Filter Sequence Numbers" on page 55.15 for more information.

ACL Rules

- The source or destination address or the protocol of each packet being filtered are tested against the filters in the ACL, one condition at a time (for a permit or a deny filter).
- If a packet does not match a filter then the packet is checked against the next filter in the ACL.
- If a packet and a filter match, the subsequent filters in the ACL are not checked and the packet is permitted or denied as specified in the matched filter.
- The first filter that the packet matches determines whether the packet is permitted or denied. After the first match, no subsequent filters are considered.
- If the ACL denies the address or protocol then the software discards the packet.
- For software ACLs, if no filters match then the packet is dropped.
- For hardware ACLs, if no filters match then the packet is forwarded.
- Checking stops after the first match, so the order of the filters in the ACL is critical. The same permit or deny filter specified in a different order could result in a packet being passed in one situation and denied in another situation.
- One ACL per interface, per protocol, per direction is allowed. However, each ACL assigned per interface, per protocol, per direction may also have multiple filters.
- For inbound ACLs, a permit filter continues to process the packet after receiving it on an inbound interface, and a deny filter discards the packet.

ACL Source and Destination Addresses

Configure source addresses in ACL filters to filter packets coming from specified networking devices or hosts. Configure destination addresses in ACL filters to filter packets going to specified networking devices or hosts.

ACL Reverse Masking

ACLs uses reverse masking, also referred to as wildcard masking, to indicate to the switch whether to check or ignore corresponding IP address bits when comparing the address bits in an ACL filter to a packet being submitted to the ACL.

Reverse masking for IP address bits specify how the switch treats the corresponding IP address bits. A reverse mask is also called an inverted mask because a 1 and 0 mean the opposite of what they mean in a subnet or a network mask.

- A reverse mask bit 0 means check the corresponding bit value.
- A reverse mask bit 1 means ignore the corresponding bit value.

Hardware and Software ACL Types

Access Control Lists (ACLs) used in AlliedWare Plus™ are separated into two different types, Software ACLs and Hardware ACLs. You can define both types as either named or numbered.

Note

The filtering principles applied to software ACLs (those in the range 1 to 2699) are different to those applied to hardware ACLs (those in the range 3000 to 4699).

Software ACLs will deny access unless explicitly permitted by an ACL action. Hardware ACLs will permit access unless explicitly denied by an ACL action.

Numbered ACLs (for Hardware and Software ACLs)

Numbered ACLs are assigned an ACL number within the range 1 to 4699. ACL numbers are grouped into ranges, where each range denotes a specific functionality. The following table shows the number ranges and functionality that your switch supports.

Table 55-1: ACL Numeric Ranges and Functionality

ACL Number Range	Function
1 to 99	IP standard ACL [1]
100 to 199	IP extended ACL [1]
1300 to 1999	IP standard expanded ACL [1]
2000 to 2699	IP extended expanded ACL [1]
3000 to 3699	Hardware IP ACL
4000 to 4699	Hardware MAC ACL

1. Software ACLs that use either the ranges 1-99, 100-199, 1300-1999, 2000-2699, or are named ACLs (that use the standard or extended keyword followed by a text string), are used in features such as SNMP, IGMP, BGP and OSPF.

Hardware ACLs

These ACL types are applied directly to an interface, or are used for QoS classifications. They use the following ranges:

- 3000-3699 for Hardware IP ACLs
- 4000-4699 for Hardware MAC ACLs
- named hardware IPv4 ACLs
- named hardware IPv6 ACLs

See Chapter 56, IPv4 Hardware Access Control List (ACL) Commands and Chapter 58, IPv6 Hardware Access Control List (ACL) Commands for detailed command information and command examples about IPv4 and IPv6 hardware ACLs that are applied directly to interfaces.

Software ACLs

These ACLs types can be either named ACLs, using the standard or extended keyword followed by a text string, or they can use the following ranges:

- 1-99 (IP standard ACL range)
- 100-199 (IP extended ACL range)
- 1300-1999 (IP standard expanded ACL range)
- 2000-2699 (IP extended expanded ACL range)
- named standard IPv4 ACLs
- named extended IPv4 ACLs
- named standard IPv6 ACLs
- named extended IPv6 ACLs

Software ACLs are used in features such as SNMP, PIM, IGMP, BGP and OSPF.

See Chapter 57, IPv4 Software Access Control List (ACL) Commands and Chapter 59, IPv6 Software Access Control List (ACL) Commands for detailed command information and command examples about IPv4 and IPv6 software ACLs as applied to Routing and Multicasting. See all relevant Routing commands and configurations in "Layer Three, Switching and Routing" and all relevant Multicast commands and configurations in "Multicast Applications".

Defining Hardware MAC ACLs

These are used to filter traffic based on specific source or destination MAC addresses contained within the data frames. They can be applied to ports in the form of access groups.

A MAC access list requires the following components:

- an ACL number in the range 4000-4699
- an action, permit, deny etc. See "Actions for Hardware ACLs" on page 55.7
- a source MAC address. You can use the format, HHHH.HHHH.HHHH to filter on a specific MAC address (where H is a hexadecimal number), or you can filter on any source MAC address by entering the word "any".
- a source MAC mask. This mask determines which portion of the source MAC address header will be compared with that found in the incoming packets. The mask is configured in the format <HHHH.HHHH.HHHH> where each H is a hexadecimal number. In practice each hex number will normally be either 0 (to represent a match) or F (to represent a don't care condition). A mask is not required if the source address is specified as "any".
- a destination MAC address. You can use the format, HHHH.HHHH.HHHH to filter on a specific MAC address (where H is a hexadecimal number), or you can filter on any destination MAC address by entering the word "any".
- a destination MAC mask. This mask determines which portion of the destination MAC address header will be compared with that found in the incoming packets. The mask is configured in the format <HHHH.HHHH.HHHH> where each H is a hexadecimal number. In practice each hex number will normally be either 0 (to represent a match) or F (to represent a don't care condition). A mask is not required if the source address is specified as "any".

Example To permit packets coming from a specific MAC address of 0030.841A.1234 and with any destination address:

```
awplus# configure terminal
awplus(config)# access-list 4000 permit 0030.841A.1234
0000.0000.0000 any
```

Defining Hardware IP ACLs

These are used to filter traffic based on specific source or destination IP addresses contained within the data frames. They can be applied to ports in the form of access groups.

An IP access list requires the following components:

- an ACL number in the range 3000-3699
- an action, see "Actions for Hardware ACLs" on page 55.7
- a packet type:
  - « IP: This matches any type of IP packet. A source and destination address must also be specified, although they can be "any".
  - « ICMP: This matches ICMP packets. A source and destination address must also be specified, although they can be "any". An ICMP type can optionally be specified after the destination address.
  - « TCP: This matches TCP packets. A source and destination address must also be specified, although they can be "any". After the source address, a source port can optionally be specified and after the destination address a destination port can optionally be specified. The port matching can be done using eq (equal to), gt (greater than), lt (less than), ne (not equal to), or range (for a range of ports, which requires a start port and an end port).
  - « UDP: This matches UDP packets and has the same options as TCP.
  - « proto: This allows any IP protocol type to be specified (e.g. 89 for OSPF). A source and destination address must be also specified, although they can be "any".

For example, to match (and permit) any type of IP packet containing a destination address of 192.168.1.1

```
awplus(config)# access-list 3000 permit ip any 192.168.1.1/32
```

To match (and permit) an ICMP packet with a source address of 192.168.x.x and an ICMP code of 4

```
awplus(config)# access-list 3001 permit icmp 192.168.0.0/16
any icmp-type 4
```

To match a TCP packet with a source address of 192.168.x.x, source port of 80 and a destination port from 100 to 150:

```
awplus(config)# access-list 3002 permit tcp 192.168.0.0/16 eq
80 any range 100 150
```

To match a UDP packet with a source address of 192.168.x.x, a destination address of 192.168.1.x, and a destination port greater than 80:

```
awplus(config)# access-list 3003 permit udp 192.168.0.0/16
                192.168.1.0/24 gt 80
```

To match to any OSPF packet:

```
awplus(config)# access-list 3004 permit proto 89 any any
```

Note that an IP address mask can be specified using either of the following notations:

- "A.B.C.D/M": This is the most common; e.g. 192.168.1.0/24
- "A.B.C.D A.B.C.D": 192.168.1.1 0.0.0.0 is the same as 192.168.1.1/32 and 192.168.1.1 255.255.255.255 is the same as "any"
- "host A.B.C.D": This is the same as A.B.C.D/32

Actions for Hardware ACLs

The following actions are available for Hardware ACLs:

- deny: Discard the packet.
- permit: Allow the packet.
- copy-to-cpu: Send a copy of the packet to the CPU and forward it as well. This is the same as copy, forward in AW hardware filters.
- send-to-cpu: Send the packet to the CPU and does not forward it. Note that specifying this action could result in EPSR healthcheck messages and other control packets being dropped.
- copy-to-mirror: Send a copy of the packet to the mirror port and forward it as well.

Attaching hardware ACLs to interfaces

A hardware ACL is attached directly to a switchport using the access-group command. For example, to permit traffic from 192.168.1.x, but discard from 192.168.x.x:

```
awplus# configure terminal
awplus(config)# access-list 3000 permit ip 192.168.1.0/24
                any
awplus(config)# access-list 3001 deny ip 192.168.0.0/24 any
awplus(config)# interface port1.0.1
awplus(config-if)# access-group 3000
awplus(config-if)# access-group 3001
```

Hardware ACLs and QoS classifications

Interface ACLs and QoS policies can both be attached to the same port. Where this is done, packets received on the port will be matched against the ACLs first.

The interface ACLs and QoS classifications are implemented by taking the first matching filter and applying the action defined for that filter. All subsequent matches in the table are then ignored. Thus, because ACLs are also matched first, if the matching ACL has a permit action, the packet is forwarded due to that rule's action and any subsequent QoS rules are bypassed.

You can also apply permit rules using QoS.

For example, you might want to permit a source IP address of 192.168.1.x, but block everything else on 192.168.x.x.

In this case you could create both the permit and deny rules using QoS.

Classifying Your Traffic

Classification is the process of filtering and marking. Filtering involves sorting your data into appropriate traffic types. Marking involves tagging the data so that downstream ports and routers can apply appropriate service policy rules.

There are two reasons to classify data:

1. To provide network security (Security ACLs)
2. To apply service quality criteria QoS.

Security ACLs

The main application of security ACLs is to block undesired traffic. Other applications include:

- copy-to-cpu
- copy-to-mirror
- send-to-cpu

For more information on these applications see “Actions for Hardware ACLs” on page 55.7

QoS ACLs

When using ACLs though QoS, the same classification and action abilities are available, but QoS has some additional fields that it can match on (see Match Commands) and also provides the ability to perform metering, marking and remarking on packets that match the filter definitions.

The action used by a QoS class-map is determined by the ACL that is attached to it. If no ACL is attached, it uses the permit action. If an ACL is not required by the class-map (for example, only matching on the VLAN) and a deny action is required, a MAC ACL should be added with `any` for source address and `any` for destination address.

The following example creates a class-map with will deny all traffic on vlan 2:

```
awplus(config)# access-list 4000 deny any any
awplus(config)# class-map cmap1
awplus(config-cmap)# match access-group 4000
awplus(config-cmap)# match vlan 2
```

The default class-map matches to all traffic and so cannot have any match or ACL commands applied to it. The action for this class-map is set via the default-action command and is `permit` by default. It can be changed to `deny` by using the following commands:

```
awplus(config)# policy-map pmap1
awplus(config-pmap)# default-action deny
```

For more information on applying QoS filtering, see "Classifying your Data" on page 60.7.

Profile Limitations

A profile is a mask that comprises 16 bytes. Each filter item that is added to the ACL set will consume a portion of the 16 bytes. Note that Hardware ACLs and QoS filters both share this single mask. However each time a mask component is defined within the mask, it can by used in many ACLs - so it is the number of different components that is important.

How many filters can you create?

The following table will help you manage your ACL mask.

Protocol Component	Bytes Used in the Mask
Protocol Type	2
Ethernet format	2
VLAN ID	2
IP protocol type (TCP, UDP, etc.)	1
source IPv4 address	4
destination IPv4 address	4
source IPv6 address[1]	0
destination IPv6 address[1]	0
TCP port number	2
UDP port number	2

Protocol Component	Bytes Used in the Mask
DSCP	1
MAC source address	6
MAC destination address	6

1. Normally any classification field, i.e. the destination MAC address, will use some of the 16 'profile bytes' that are available to classify incoming packets. For example an ACL with both source and destination MAC address fields set, will consume 12 of the 16 bytes. However the classification fields IPv6 Next Header, and IPv6 source and destination address will not consume any of these bytes, allowing greater freedom in ACL configuration options.

Hardware Filter Example

If you make a hardware filter that matches on destination IP address and source TCP port, this adds 7 bytes to the mask:

- 1 byte for the IP protocol field (to indicate TCP)
- 4 bytes for the destination IP address
- 2 bytes for the source TCP port number.

If you now create the following (additional) hardware filters:

- A hardware filter that matches on source MAC address. This adds 6 more bytes to the mask
- A QoS class map that matches on destination IP address (4 bytes) and DSCP (1 byte). This adds 1 more byte to the mask, for the DSCP. Note that it does not add 4 more bytes for the destination IP address, because the switch already matches on that field.
- A hardware filter that matches on source IP address and source TCP port. This does not change the mask, because the switch already matches on those fields.
- A hardware filter that matches on source UDP port. This does not add any length to the mask, because it shares the same 2 bytes as the source TCP port. However, if you next make a hardware filter that matches on destination TCP or UDP port, that uses another 2 bytes.

Are there now enough bytes for your set of filters?

The mask has a maximum size of 16 bytes. When it reaches the 16-byte limit, no more classifiers can be used that would cause the mask to increase in size. The switch can still accept classifiers that use fields that have already been included in the mask.

There is no particular number of hardware filters or QoS flow groups that will cause the mask to reach its 16-byte limit - it could happen after a few filters, or you might be able to create hundreds of filters without the mask reaching its limit.

So to determine whether you will have enough filter length, look at the fields you want to filter, determine the number of bytes for each field, and sum up the total number of bytes. If that number is less than 16, there is enough filter length. Don't forget to count TCP and UDP source port as a single field, and likewise to count TCP and UDP destination port as a single field.

Attaching hardware ACLs using QoS

The same functionality can be achieved using QoS, by attaching the ACL to a class-map, attaching the class-map to a policy-map and attaching the policy-map to a port:

Step 1: Enable QoS on the switch

```
awplus(config)# mls qos enable
```

Step 2: Create access lists

Create ACL `3000` to permit all packets from the 192.168.1 subnet:

```
awplus(config)# access-list 3000 permit ip 192.168.1.0/24 any
```

Create ACL `3001` to deny all packets from the 192.168.0 subnet.:

```
awplus(config)# access-list 3001 deny ip 192.168.0.0/24 any
```

Step 3: Attach access-groups to class-maps

Attach ACL `3000` to the class-map `cmap1`:

```
awplus(config)# class-map cmap1
awplus(config-cmap)# match access-group 3000
awplus(config-cmap)# exit
```

Attach ACL `3001` to the same class-map (`cmap2`):

```
awplus(config-cmap)# match access-group 3001
awplus(config-cmap)# exit
```

Step 4: Attach class-maps to policy-maps

Attach the class-map `cmap1` to policy-map `pmap1`:

```
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# exit
```

Add the class-map `cmap2` to the policy-map `pmap1`:

```
awplus(config-pmap)# class cmap2
awplus(config-pmap-c)# exit
```

Return to Global Configuration mode:

```
awplus(config-pmap)# exit
```

Step 5: Add policy-maps to ports

Add policy-map `pmap1` to `port1.0.1`:

```
awplus(config)# interface port1.0.1
awplus(config-if)# service-policy input pmap1
```

Note that multiple interface ACLs can be attached to the same port, or either type and can be interleaved. The order of matching is based on the order in which the ACLs were attached to the port. Only one ACL can be attached to a class-map, but multiple class-maps can be attached to a policy-map. Interface ACLs can be attached to the same port as a QoS policy, with the interface ACLs being matched first as described at the beginning of the Classification section.

Filtering hardware ACLs with QoS

Another reason for using QoS rather than interface ACLs is that QoS provides a lot more fields on which to match. These are accessed through the match commands in config-cmap mode.

Config-cmap mode describes the fields that can be matched on. Only one of each type can be matched, with the exception of tcp-flags (see below for classification). If multiple matches are specified, they are ANDed together.

The following example shows how you can match a packet on vlan 2, that has a source IP address of 192.168.x.x and a DSCP of 12:

Create ACL `3000` to permit all packets from the 192.168 subnet.:

```
awplus# configure terminal
awplus(config)# access-list 3000 permit ip 192.168.0.0/16 any
```

Apply ACL 3000 to the class-map cmap1 and add the matching criteria of vlan 2 and DSCP 12:

```
awplus(config)# class-map cmap1
awplus(config-cmap)# match access-group 3000
awplus(config-cmap)# match vlan 2
awplus(config-cmap)# match dscp 12
awplus(config-cmap)# exit
```

Using QoS Match Commands with TCP Flags

Usually, if multiple matches of the same type are specified, the matching process will apply to the last match that you specified. For TCP flags however, the arguments are ANDed together. For example, the following series of commands will match on a packet that has ack, syn and fin set:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match tcp-flags ack
awplus(config-cmap)# match tcp-flags syn
awplus(config-cmap)# match tcp-flags fin
awplus(config-cmap)# exit
```

The following commands will achieve the same result:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match tcp-flags ack syn fin
awplus(config-cmap)# exit
```

Note that the matching is looking to see whether “any” of the specified flags are set. There is no checking for whether any of these flags are unset. Therefore the following commands will match on a packet in any of the following combinations of syn and ack status flags as shown in the following table:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match tcp-flags syn
awplus(config-cmap)# exit
```

Syn	Ack	Match on Packet
Set	Set	Yes
Set	Unset	Yes
Unset	Set	No
Unset	Unset	No

If you want to drop packets with syn only, but not with ack and syn, the following two class-maps can be used (note that ACL 4000 is used to apply a drop action as described in “Actions for Hardware ACLs” on page 55.7):

Step 1: Create access lists

Create ACL `4000` to deny all packets with `any` source or destination address:

```
awplus# configure terminal
awplus(config)# access-list 4000 deny any any
```

Step 2: Create class-maps

Create the class-map `cmap1` and configure it to match on the TCP flags, `ack` and `syn`:

```
awplus(config)# class-map cmap1
awplus(config-cmap)# match tcp-flags ack syn
awplus(config-cmap)# exit
```

Create the class-map `cmap2` and configure it to match on the TCP flag, `syn`:

```
awplus(config)# class-map cmap2
awplus(config-cmap)# match tcp-flags syn
```

Step 3: Apply access-groups to class-maps

Apply ACL `4000` to this class-map (i.e. to `cmap2`):

```
awplus(config-cmap)# match access-group 4000
awplus(config-cmap)# exit
```

Step 4: Create policy-maps

Create the policy-map pmap1 and associate it with cmap1:

```
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# exit
```

Step 5: Associate class-maps with policy-maps

Associate `cmap2` with this policy-map (`pmap1`):

```
awplus(config-pmap)# class cmap2
awplus(config-pmap-c)# exit
```

ACL Filter Sequence Numbers

To help you manage ACLs you can apply sequence numbers to filters. This allows you to remove filters from named and numbered ACLs without having to reconfigure an ACL.

The ability to add sequence numbers to filters simplifies updates through the ability to position a filter within an ACL. When you add a new filter, you can specify a sequence number to position the filter in the ACL and you can also remove a current filter in an ACL by specifying a sequence number.

ACL Filter Sequence Number Behavior

- If filters with no sequence numbers are applied then the first filter is assigned a sequence number of 10, and successive filters are incremented by 10. Sequence numbers are generated automatically if they are not specified at entry.
- The maximum filter sequence number is 65535. If the sequence number exceeds this maximum, the command will not be recognized and will show the error message:
  `% Unrecognized command`
- If you enter a filter without a sequence number it is assigned a sequence number that is 10 greater than the last sequence number and is placed at the end of the ACL.
- If you enter a filter that matches an already existing filter then the first filter is overwritten with the subsequent filter.
- ACL sequence numbers determine the order of execution of filters in an ACL. Filters in a ACL with a lower value sequence number are executed before filters with a higher value.
- Output from show running-config displays ACL entries without filter sequence numbers. Output from relevant show commands displays ACL entries with their sequence numbers.
- ACL sequence numbers are re-numbered upon switch restart following a reload command, or after powering off and powering on the switch. ACL sequence numbers are renumbered starting from 10 and increment by 10 for each filter. See the sample output in the configuration section that follows for an illustration of this behavior. No ACL sequence number re-number command is available to perform this action.
- The ACL sequence number feature works with numbered and named standard and extended IPv4 and IPv6 access lists, plus named hardware IPv4 and IPv6 access lists
- The name of an access list can be designated as a number. Number in named ACLs must not exist within the range or designated numbered ACLs. (where <1-99> and <1300-1999> are standard numbered ACLs, <100-199> and <2000-2699> are extended numbered ACLs, <3000-3699> and <4000-4699> are hardware numbered ACLs).

ACL Filter Sequence Number Applicability

The ACL sequence number support feature is available with numbered and named standard and extended IPv4 and IPv6 ACLs, and the named hardware IPv4 and IPv6 ACLs.

Numbered standard ACLs are available in the range <1-99> and <1300-1999>, which permit or deny source addresses to control packets coming from network devices or hosts, in software.

Numbered extended ACLs are available in the range <100-199> and <2000-2699>, which permit or deny source addresses and destination addresses (plus ICMP, TCP, UDP messages) to control packets coming from and going to network devices or hosts.

Named hardware IPv4 and IPv6 ACLs are available which permit or deny IP and MAC source and destination addresses plus VLAN IDs to control packets coming from and going to network device and hosts. Named hardware IPv4 and IPv6 ACLs use the ACL sequence number support feature for ACL revision.

The ACL sequence number support feature is available for use with named hardware IPv4 and IPv6 ACLs, but this feature is not available for use with the numbered hardware IPv4 ACLs.

Numbered hardware ACLs are available in the range <3000-3699>, which permit or deny IP source addresses, IP destination addresses, and VLAN IDs to control packets coming from and going to network devices and hosts, in hardware.

Numbered hardware ACLs are available in the range <4000-4699>, which permit or deny MAC source addresses, MAC destination addresses, and VLAN IDs to control packets coming from and going to network devices and hosts, in hardware.

ACL Filter Sequence Number Types

There are ACL filter sequence numbers available for the following types of ACLs:

ACL Type	ACL Command Syntax
IPv4 Standard Numbered ACLs	access-list <1-99> access-list <1300-1999>
IPv4 Extended Numbered ACLs	access-list <100-199> access-list <2000-2699>
IPv4 Standard Named ACLs	access-list standard <*name*>
IPv4 Extended Named ACLs	access-list extended <*name*>
IPv4 Hardware Named ACLs	access-list hardware <*name*>
IPv6 Standard Named ACLs	ipv6 access-list standard <*name*>
IPv6 Extended Named ACLs	ipv6 access-list extended <*name*>
IPv6 Hardware Named ACLs	ipv6 access-list <*name*>

Note that ACL sequence number support for these ACL commands is optional not required. An ACL sequence number will be added automatically, starting at 10 and incrementing by 10.

ACL Commands Without ACL Filter Sequence Numbers

ACL filter sequence numbers is not available for numbered hardware ACL commands:

access-list <3000-3699>
access-list <4000-4699>

ACL Filter Sequence Number Entry Examples

See the below CLI entry examples for prompt sub-modes for ACL filters after ACL commands:

- To create an IPv4 Standard ACL and then define ACL filters at the IPv4 Standard ACL Configuration mode prompt awplus(config-ip-std-acl)#, enter the following commands:

```
awplus(config)# access-list 1
awplus(config-ip-std-acl)# permit 192.168.1.0 0.0.0.255

awplus(config)# access-list standard std_name
awplus(config-ip-std-acl)# permit 192.168.1.0/24
```

- To create an IPv4 Extended ACL and then define ACL filters at the IPv4 Extended ACL Configuration mode prompt awplus(config-ip-ext-acl)#, enter the following commands:

```
awplus(config)# access-list 100
awplus(config-ip-ext-acl)# permit ip 192.168.1.0 0.0.0.255
                           192.168.2.0 0.0.0.255

awplus(config)# access-list extended ext_name
awplus(config-ip-ext-acl)# permit ip 192.168.1.0 0.0.0.255
                           192.168.2.0 0.0.0.255
```

- To create an IPv4 Hardware ACL and then define ACL filters at the IPv4 Hardware ACL Configuration mode prompt awplus(config-ip-hw-acl)#, enter the following commands:

```
awplus(config)# access-list hardware hw_name
awplus(config-ip-hw-acl)# permit ip 192.168.1.0 0.0.0.255
                           192.168.2.0 0.0.0.255
```

- To create an IPv6 Standard ACL and then define ACL filters at the IPv6 Standard ACL Configuration mode prompt awplus(config-ipv6-std-acl)#, enter the following commands:

```
awplus(config)# ipv6 access-list standard
                ipv6_std_name
awplus(config-ipv6-std-acl)# permit 2001:db8::/64
```

- To create an IPv6 Extended ACL and then define ACL filters at the IPv6 Extended

Configuration mode prompt awplus(config-ipv6-ext-acl)#, enter the following commands:

```
awplus(config)# ipv6 access-list extended
                ipv6_ext_name
awplus(config-ipv6-ext-acl)# permit ip 2001:db8::/64
                2001:db9::/64
```

- To create an IPv6 Hardware ACL and then define ACL filters at the IPv6 Hardware Configuration mode prompt awplus(config-ipv6-hw-acl)#, enter the following commands:

```
awplus(config)# ipv6 access-list ipv6_hw_name
awplus(config-ipv6-hw-acl)# permit ip 2001:db8::/64 2001:db9::/
                64
```

ACL Filter Sequence Configuration

First create a named or numbered ACL to enter ACL filters in the ACL sub-modes available:

Step 1: Create a new ACL and add a new filter

Create ACL `10` and then add a new filter to the access-list to permit all packets from the `192.168.1` subnet:

```
awplus# configure terminal
awplus(config)# access-list 10
awplus(config-ip-std-acl)# permit 192.168.1.0 0.0.0.255
awplus(config-ip-std-acl)# end
awplus# show access-list 10
```

```
Standard IP access list 10
   10 permit 192.168.1.0, wildcard bits 0.0.0.255
```

Step 2: Add another filter to the ACL

Append to, or add at the end of, ACL `10` a new filter to deny all packets from the `192.168.2` subnet:

```
awplus# configure terminal
awplus(config)# access-list 10
awplus(config-ip-std-acl)# deny 192.168.2.0 0.0.0.255
awplus(config-ip-std-acl)# end
awplus# show access-list 10
```

```
Standard IP access list 10
   10 permit 192.168.1.0, wildcard bits 0.0.0.255
   20 deny   192.168.2.0, wildcard bits 0.0.0.255
```

Note that if you add a filter to an ACL without specifying a sequence number the new filter is automatically assigned a sequence number. Sequence numbers are assigned in multiples of ten from the sequence number of the last filter.

Step 3: Insert a filter into the ACL

Insert a new filter with the sequence number `15` into ACL `10` to permit packets from the `192.168.3` subnet:

```
                    awplus# configure terminal
             awplus(config)# access-list 10
awplus(config-ip-std-acl)# 15 permit 192.168.3.0 0.0.0.255
awplus(config-ip-std-acl)# end
                    awplus# show access-list 10
```

```
Standard IP access list 10
   10 permit 192.168.1.0, wildcard bits 0.0.0.255
   15 permit 192.168.3.0, wildcard bits 0.0.0.255
   20 deny   192.168.2.0, wildcard bits 0.0.0.255
```

The new filter has precedence over the filter with the sequence number `20`.

Step 4: Remove a filter from the ACL by specifying a filter pattern

Remove the filter with the IP address `192.168.2` from ACL `10`:

```
                    awplus# configure terminal
             awplus(config)# access-list 10
awplus(config-ip-std-acl)# no deny 192.168.2.0 0.0.0.255
awplus(config-ip-std-acl)# end
                    awplus# show access-list 10
```

```
Standard IP access list 10
   10 permit 192.168.1.0, wildcard bits 0.0.0.255
   15 permit 192.168.3.0, wildcard bits 0.0.0.255
```

Step 5: Remove a filter from the ACL by specifying a sequence number

Remove the filter with the sequence number `10` from ACL `10`:

```
                awplus# configure terminal
          awplus(config)# access-list 10
awplus(config-ip-std-acl)# no 10
awplus(config-ip-std-acl)# end
                awplus# show access-list
```

```
Standard IP access list 10
   15 permit 192.168.3.0, wildcard bits 0.0.0.255
```

Creating ACLs in Global Configuration Mode

You can add new filters in Global Configuration mode with the access-list extended (named) command on page 57.4. In this mode the filters are assigned a sequence number corresponding to the order in which there are entered, i.e. the first filter entered has higher precedence in the ACL.

Step 1: Add filters with the **access-list** command

Add filters to ACL `10` using the access-list command:

```
        awplus# configure terminal
awplus(config)# access-list 10 permit 192.168.1.0 0.0.0.255
awplus(config)# access-list 10 deny 192.168.2.0 0.0.0.255
awplus(config)# end
        awplus# show access-list 10
```

```
Standard IP access list 10
   15 permit 192.168.3.0, wildcard bits 0.0.0.255
   20 permit 192.168.1.0, wildcard bits 0.0.0.255
   30 deny 192.168.2.0, wildcard bits 0.0.0.255
```

You can then enter the IPv4 Standard ACL Configuration mode and use the (access-list standard named filter) command on page 57.32 to specify sequence numbers to reorder the filters.

Step 2: Reorder the filters

Reorder the filters in ACL `10` by specifying a sequence number for each filter. The specified sequence number will overwrite the previous sequence number assigned to the filter:

```
                awplus# configure terminal
          awplus(config)# access-list 10
awplus(config-ip-std-acl)# 1021 permit 192.168.1.0 0.0.0.255
awplus(config-ip-std-acl)# 3333 permit 192.168.3.0 0.0.0.255
awplus(config-ip-std-acl)# 2772 deny 192.168.2.0 0.0.0.255
awplus(config-ip-std-acl)# end
                awplus# show access-list 10
```

```
Standard IP access list 10
 1021 permit 192.168.1.0, wildcard bits 0.0.0.255
 2772 deny   192.168.2.0, wildcard bits 0.0.0.255
 3333 permit 192.168.3.0, wildcard bits 0.0.0.255
```

Step 3: Copy the running-config file into the startup-config file

Copy the running-config into the file set as the current startup-config file and then reload the device. Before the reload occurs, you will receive a confirmation request saying: "`reboot system? (y/n):`".

When the device has reboot you can then enter Global Configuration mode and use the show access-group command to display ACL `10`:

```
awplus(config)# exit
       awplus# copy running-config startup-config
       awplus# reload
       awplus# show access-list 10
```

```
Standard IP access list 10
   10 permit 192.168.1.0, wildcard bits 0.0.0.255
   20 deny   192.168.2.0, wildcard bits 0.0.0.255
   30 permit 192.168.3.0, wildcard bits 0.0.0.255
```

After the device has reboot the sequence numbers of the filters in the ACL have been reassigned incrementing from 10.

Display the ACL configuration details

Display the running system status and configuration details for ACLs:

```
awplus# show running-config access-list
```

```
!
access-list 1 deny 10.1.1.0 0.0.0.255
access-list 1 permit any
access-list 2
access-list 5
access-list 10 permit 192.168.1.0 0.0.0.255
access-list 10 deny 192.168.2.0 0.0.0.255
access-list 10 permit 192.168.3.0 0.0.0.255
access-list 20
access-list 25 permit 10.1.2.0 0.0.0.255
access-list 25 deny 192.168.1.0 0.0.0.255
access-list 50
access-list 95 permit any
access-list 100
access-list 1300
access-list 2000
access-list extended acl
access-list extended my-list
access-list extended name
access-list extended name1
access-list standard name3
ipv6 access-list extended ipv6_acl
ipv6 access-list standard ipv6_acl2
ipv6 access-list extended my-ipv6-list
ipv6 access-list extended my-list
ipv6 access-list standard my-new-list
ipv6 access-list standard name
ipv6 access-list standard name1 deny any
ipv6 access-list extended name5
ipv6 access-list standard name6
access-list hw_acl
access-list icmp
access-list my-hw-list
access-list name2
access-list name4
!
```

For more information see show running-config access-list command on page 7.39.

(access-list hardware MAC filter) 56.30
(access-list hardware TCP UDP filter) 56.33
commit (IPv4) 56.37
show access-group 56.38
show access-list (IPv4 Hardware ACLs) 56.39
show interface access-group 56.41

Introduction

This chapter provides an alphabetical reference for the IPv4 Hardware Access Control List (ACL) commands, and contains detailed command information and command examples about IPv4 hardware ACLs, which are applied directly to interfaces using the access-group command.

Note

See Chapter 55, Access Control Lists Introduction for descriptions of ACLs, and for further information about rules when applying ACLs see the ACL Rules section.

See ACL Filter Sequence Numbers and ACL Filter Sequence Number Behavior sections in Chapter 55, Access Control Lists Introduction about ACL Filters.

To apply ACLs to an LACP channel group, apply it to all the individual switch ports in the channel group. To apply ACLs to a static channel group, apply it to the static channel group itself. For more information on link aggregation see Chapter 20, Link Aggregation Introduction and Configuration, and Chapter 21, Link Aggregation Commands.

Note

Text in parenthesis in command names indicates usage not keyword entry. For example, access-list hardware (named) indicates named IPv4 hardware ACLs entered as `access-list hardware` <*name*> where <*name*> is a placeholder not a keyword.

Note

Parenthesis surrounding ACL filters indicates the type of ACL filter not the keyword entry in the CLI, such as (access-list standard numbered filter) represents command entry in the format shown in the syntax `[<sequence-number>] {deny|permit} {<source>|host <host-address>|any}`.

Note

Software ACLs will deny access unless explicitly permitted by an ACL action.

IPv4 Hardware Access List Commands and Prompts

Many of the ACL commands operate from sub-modes that are specific to particular ACL types. The table "IPv4 Hardware Access List Commands and Prompts" shows the CLI prompts at which ACL commands are entered.

Table 56-1: IPv4 Hardware Access List Commands and Prompts

Command Name	Command Mode	Prompt
show interface access-group	Privileged Exec	awplus#
show access-group	Privileged Exec	awplus#
show access-list (IPv4 Hardware ACLs)	Privileged Exec	awplus#
show interface access-group	Privileged Exec	awplus#
access-group	Global Configuration	awplus(config)#
access-list (hardware IP numbered)	Global Configuration	awplus(config)#
access-list (hardware MAC numbered)	Global Configuration	awplus(config)#
access-list hardware (named)	Global Configuration	awplus(config)#
access-group	Interface Configuration	awplus(config-if)#
(access-list hardware ICMP filter)	IPv4 Hardware ACL Configuration	awplus(config-ip-hw-acl)#
(access-list hardware IP protocol filter)	IPv4 Hardware ACL Configuration	awplus(config-ip-hw-acl)#
(access-list hardware MAC filter)	IPv4 Hardware ACL Configuration	awplus(config-ip-hw-acl)#
(access-list hardware TCP UDP filter)	IPv4 Hardware ACL Configuration	awplus(config-ip-hw-acl)#
commit (IPv4)	IPv4 Hardware ACL Configuration	awplus(config-ip-hw-acl)#

Command List

access-group

This command adds or removes a hardware-based access-list to a switch port interface. The number of hardware numbered and named access-lists that can be added to a switch port interface is determined by the available memory in hardware-based packet classification tables. This command works in both Global Configuration and Interface Configuration modes to apply hardware access-lists to all switch port interfaces or selected switch port interfaces respectively.

The no variant of this command removes the selected access-list from an interface.

Syntax

```
access-group [<3000-3699>|<4000-4699>|<hardware-access-list-name>]
no access-group [<3000-3699>|4000-4699|<hardware-access-list-name>]
```

Parameter	Description
<3000-3699>	Hardware IP access-list.
<4000-4699>	Hardware MAC access-list.
<hardware-access-list-name>	The hardware access-list name.

Mode Interface Configuration or Global Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicitly match a filter is permitted.

Usage First create an IP access-list that applies the appropriate permit, deny requirements etc with the access-list (hardware IP numbered) command on page 56.6, the access-list (hardware MAC numbered) command on page 56.16 or the access-list hardware (named) command on page 56.19. Then use this command to apply this hardware access-list to a specific port or port range. Note that this command will apply the access-list only to incoming data packets.

To apply ACLs to an LACP aggregated link, apply it to all the individual switch ports in the aggregated group. To apply ACLs to a static channel group, apply it to the static channel group itself. Do not apply an ACL to a dynamic (LACP) or static aggregated link that spans more than one switch instance (Chapter 21, Link Aggregation Commands).

Note that you cannot apply software standard and extended numbered ACLs to switch port interfaces with the access-group command. This command will only apply hardware ACLs.

Note Hardware ACLs will permit access unless explicitly denied by an ACL action.

Examples To add the numbered hardware access-list `3005` to all switch ports, enter the following commands:

```
awplus# configure terminal
awplus(config)# access-group 3005
```

To add the numbered hardware access-list `3005` to switch port interface `port1.0.1`, enter the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# access-group 3005
```

To add the named hardware access-list `hw-acl` to switch port interface `port1.0.2`, enter the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# access-group hw-acl
```

To apply an ACL to static channel group 2 containing switch `port1.0.5` and `port1.0.6`, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.5-1.0.6
awplus(config-if)# static-channel-group 2
awplus(config)# interface sa2
awplus(config-if)# access-group 3000
```

Related Commands

access-list hardware (named)
access-list (hardware IP numbered)
access-list (hardware MAC numbered)
show interface access-group

access-list (hardware IP numbered)

This command creates an access-list for use with hardware classification, such as QoS. The access-list will match on either TCP or UDP type packets that have the specified source and destination IP addresses and Layer 4 port values or ranges. The parameter any may be specified if an address does not matter and the port values are optional.

Note that specifying the send-to-cpu parameter could result in EPSR healthcheck messages and other control packets being dropped.

The optional vlan parameter can be applied to match tagged (802.1q) packets.

The no variant of this command removes the previously specified IP hardware access-list.

Syntax [ip]

```
access-list <3000-3699>
   {deny|permit|copy-to-cpu|copy-to-mirror|send-to-cpu} ip <source>
   <destination> [vlan <1-4094>]
```

Syntax [icmp]

```
access-list <3000-3699>
   {deny|permit|copy-to-cpu|copy-to-mirror|send-to-cpu} icmp
   <source> <destination> [icmp-type <type-number>]
   [vlan <1-4094>]
```

```
no access-list <3000-3699>
```

Table 56-2: Parameters in the access-list (hardware IP numbered) command - ip|icmp

Parameter	Description
<3000-3699>	Hardware IP access-list number.
deny	Access-list rejects packets that match the source and destination filtering specified with this command.
permit	Access-list permits packets that match the source and destination filtering specified with this command.
copy-to-cpu	Specify packets to copy to the CPU.
copy-to-mirror	Specify packets to copy to the mirror port.
send-to-cpu	Specify packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.
icmp	ICMP packet.
ip	IP packet.

Table 56-2: Parameters in the access-list (hardware IP numbered) command - ip|icmp(cont.)

Parameter(cont.)	**Description**(cont.)	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	`any`	Matches any source IP address.
	`host` *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>`/`*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	`any`	Matches any destination IP address.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>`/`*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
`icmp-type`	Matches only a specified type of ICMP messages. This is valid only when the filtering is set to match ICMP packets.	

Table 56-2: Parameters in the access-list (hardware IP numbered) command - ip|icmp(cont.)

Parameter(cont.)	**Description**(cont.)	
<type-number>	The ICMP type, as defined in RFC792 and RFC950. Specify one of the following integers to create a filter for the ICMP message type:	
	0	Echo replies.
	3	Destination unreachable messages.
	4	Source quench messages.
	5	Redirect (change route) messages.
	8	Echo requests.
	11	Time exceeded messages.
	12	Parameter problem messages.
	13	Timestamp requests.
	14	Timestamp replies.
	15	Information requests.
	16	Information replies.
	17	Address mask requests.
	18	Address mask replies.
`vlan`	Specifies that the ACL will match on the ID in the packet's VLAN tag.	
<1-4094>	The VLAN VID.	

Syntax [tcp|udp]

```
access-list <3000-3699>
    {copy-to-cpu|copy-to-mirror|deny|permit|send-to-cpu} {tcp|udp}
    <source>
    {eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>|
    [range <start-range> <end-range>}
    <destination>
    [eq <destport>|lt <destport>|gt <destport>|ne <destport>]
    [range <start-range> <end-range>]

no access-list <3000-3699>
```

Table 56-3: Parameters in the access-list (hardware IP numbered) command - tcp|udp

Parameter	Description	
<3000-3699>	Hardware IP access-list.	
copy-to-cpu	Specify packets to copy to the CPU.	
copy-to-mirror	Specify packets to copy to the mirror port.	
deny	The access-list rejects packets that match the type, source, and destination filtering specified with this command.	
permit	The access-list permits packets that match the type, source, and destination filtering specified with this command.	
send-to-cpu	Specify packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.	
tcp	The access-list matches only TCP packets.	
udp	The access-list matches only UDP packets.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	any	Matches any source IP address.
	host *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering 192.168.1.1 0.0.0.255 is the same as entering 192.168.1.1/24.

Table 56-3: Parameters in the access-list (hardware IP numbered) command - tcp|udp(cont.)

Parameter(cont.)	**Description**(cont.)	
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	`any`	Matches any destination IP address.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
<sourceport>	The source (TCP or UDP) port number, specified as an integer between 0 and 65535.	
`range`	Range of port numbers.	
<start-range>	Port number at start of range *<0-65535>*.	
<end-range>	Port number at end of range *<0-65535>*.	
<destport>	The destination (TCP or UDP) port number, specified as an integer between 0 and 65535.	
`eq`	Matches port numbers that are equal to the port number specified immediately after this parameter.	
`lt`	Matches port numbers that are less than the port number specified immediately after this parameter.	
`gt`	Matches port numbers that are greater than the port number specified immediately after this parameter.	
`ne`	Matches port numbers that are not equal to the port number specified immediately after this parameter.	
`range`	Range of port numbers.	
<start-range>	Port number at start of range *<0-65535>*.	
<end-range>	Port number at end of range *<0-65535>*.	
`vlan`	Specifies that the ACL will match on the ID in the packet's VLAN tag.	
<1-4094>	The VLAN VID.	

Syntax [proto]

```
access-list <3000-3699>
    {copy-to-cpu|copy-to-mirror|deny|permit|send-to-cpu} proto <ip-
    protocol> <source> <destination>

no access-list <3000-3699>
```

Table 56-4: Parameters in the access-list (hardware IP numbered) command - proto

Parameter	Description	
<3000-3699>	Hardware IP access-list.	
copy-to-cpu	Specify packets to copy to the CPU.	
copy-to-mirror	Specify packets to copy to the mirror port.	
deny	Access-list rejects packets that match the source and destination filtering specified with this command.	
permit	Access-list permits packets that match the source and destination filtering specified with this command.	
send-to-cpu	Specify packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	any	Matches any source IP address.
	host *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering 192.168.1.1 0.0.0.255 is the same as entering 192.168.1.1/24.

Table 56-4: Parameters in the access-list (hardware IP numbered) command - proto

Parameter(cont.)	**Description**(cont.)	
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	`any`	Matches any destination IP address.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>`/`*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
`proto`	Matches only a specified type of IP Protocol <1-255>.	
<ip-protocol>	The IP protocol number, as defined by IANA (Internet Assigned Numbers Authority http://www.iana.org/assignments/protocol-numbers)	
	Protocol Number	Protocol Description [RFC Reference]
	1	Internet Control Message [RFC792]
	2	Internet Group Management [RFC1112]
	3	Gateway-to-Gateway [RFC823]
	4	IP in IP [RFC2003]
	5	Stream [RFC1190] [RFC1819]
	6	TCP (Transmission Control Protocol) [RFC793]
	8	EGP (Exterior Gateway Protocol) [RFC888]
	9	IGP (Interior Gateway Protocol) [IANA]
	11	Network Voice Protocol [RFC741]
	17	UDP (User Datagram Protocol) [RFC768]
	20	Host monitoring [RFC869]
	27	RDP (Reliable Data Protocol) [RFC908]
	28	IRTP (Internet Reliable Transaction Protocol) [RFC938]
	29	ISO-TP4 (ISO Transport Protocol Class 4) [RFC905]

Table 56-4: Parameters in the access-list (hardware IP numbered) command - proto

Parameter(cont.)	**Description**(cont.)	
<ip-protocol>	30	Bulk Data Transfer Protocol [RFC969]
(cont.)	33	DCCP (Datagram Congestion Control Protocol) [RFC4340]
	48	DSR (Dynamic Source Routing Protocol) [RFC4728]
	50	ESP (Encap Security Payload) [RFC2406]
	51	AH (Authentication Header) [RFC2402]
	54	NARP (NBMA Address Resolution Protocol) [RFC1735]
	58	ICMP for IPv6 [RFC1883]
	59	No Next Header for IPv6 [RFC1883]
	60	Destination Options for IPv6 [RFC1883]

	112	Virtual Router Redundancy Protocol / RFC3768
	134	RSVP-E2E-IGNORE / RFC3175
	135	Mobility Header / RFC3775
	136	UDPLite / RFC3828
	137	MPLS-in-IP / RFC4023
	138	MANET Protocols / RFC-ietf-manet-iana-07.txt
	139-252	Unassigned / IANA
	253	Use for experimentation and testing / RFC3692
	254	Use for experimentation and testing / RFC3692
	255	Reserved / IANA
vlan	Specifies that the ACL will match on the ID in the packet's VLAN tag.	
<1-4094>	The VLAN VID.	

Mode Global Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicitly match a filter is permitted.

Usage This command creates an access-list for use with hardware classification, such as when applying QoS. This command can be used to match ICMP packets, IP protocols, or TCP/UDP packets.

For ICMP packets, the <3000-3699> range IP hardware access-list will match any ICMP packet that has the specified source and destination IP addresses and ICMP type.

You may apply the any parameter if the source or destination IP address is not important. The ICMP type is an optional parameter.

Note Hardware ACLs will permit access unless explicitly denied by an ACL action.

Examples Follow the below example commands to configure access-lists for ICMP, IP protocol and TCP.

ICMP Example To create an access-list that will permit ICMP packets with a source address of `192.168.1.0/24` with any destination address and an ICMP type of `5` enter the below commands:

```
awplus# configure terminal
awplus(config)# access-list 3000 permit icmp 192.168.1.0/24
any icmp-type 5
```

To destroy the access-list with an access-list identity of `3000` enter the below commands:

```
awplus# configure terminal
awplus(config)# no access-list 3000
```

IP Example To create an access-list that will permit any type of IP packet with a source address of `192.168.1.1` and any destination address, enter the commands:

```
awplus# configure terminal
awplus(config)# access-list 3000 permit ip 192.168.1.1/32 any
```

To create an access-list that will deny all IGMP packets (IP protocol `2`) from the `192.168.0.0` network, enter the commands:

```
awplus# configure terminal
awplus(config)# access-list 3000 deny proto 2 192.168.0.0/16 any
```

TCP Example To create an access-list that will permit TCP packets with a destination address of `192.168.1.1`, a destination port of 80 and any source address and source port, enter the commands:

```
awplus# configure terminal
awplus(config)# access-list 3000 permit tcp any 192.168.1.1/32
eq 80
```

copy-to-mirror Example

To create an access-list that will copy-to-mirror TCP packets with a destination address of `192.168.1.1`, a destination port of 80 and any source address and source port for use with the mirror interface command, enter the commands:

```
awplus# configure terminal

awplus(config)# access-list 3000 copy-to-mirror tcp any
192.168.1.1/32 eq 80
```

Related Commands

access-group
mirror interface
show running-config
show access-list (IPv4 Hardware ACLs)

access-list (hardware MAC numbered)

This command creates an access-list for use with hardware classification, such as QOS. The access-list will match on packets that have the specified source and destination MAC addresses. The parameter any may be specified if an address does not matter.

Note that specifying the send-to-cpu parameter could result in EPSR healthcheck messages and other control packets being dropped.

Optionally, the vlan and inner-vlan parameters can be matched for tagged (802.1q) packets.

The no variant of this command removes the specified MAC hardware filter access-list.

Syntax

```
access-list <4000-4699>
   {copy-to-cpu|copy-to-mirror|deny|permit|send-to-cpu}
   {<source-mac-address> <source-mac-mask>|any}
   {<destination-mac-address> <destination-mac-mask>|any}
   [vlan <1-4094> [inner-vlan <1-4094>]]

no access-list <4000-4699>
```

Parameter	Description
<4000-4699>	Hardware MAC access-list.
copy-to-cpu	Specify packets to copy to the CPU.
copy-to-mirror	Specify packets to copy to the mirror port.
deny	Access-list rejects packets that match the source and destination filtering.
permit	Access-list permits packets that match the source and destination filtering.
send-to-cpu	Specify packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.
<source-mac-address>	The source MAC address of the packets. Enter this in the format <HHHH.HHHH.HHHH> Where each *H* is a hexadecimal number that represents a 4 bit binary number.
<source-mac-mask	The mask that will be applied to the source MAC addresses. Enter this in the format <HHHH.HHHH.HHHH> Where each *H* is a hexadecimal number that represents a 4 bit binary number. For a mask, each value will be either 0 or F. Where Hex FF = Ignore, and Hex 00 = Match.
any	Any source MAC address.
<destination-mac-address>	The destination MAC address of the packets. Enter this in the format <HHHH.HHHH.HHHH> Where each H is a hexadecimal number that represents a 4 bit binary number.
<destination-mac-mask>	The mask that will be applied to the destination MAC addresses. Enter this in the format <HHHH.HHHH.HHHH> Where each H is a hexadecimal number that represents a 4 bit binary number. For a mask, each value will be either 0 or F. Where Hex FF = Ignore, and Hex 00 = Match.

Parameter(cont.)	**Description**(cont.)
`any`	Any destination MAC address.
`vlan`	Specifies that the ACL will match on the ID in the packet's VLAN tag.
<1-4094>	The VLAN VID.
`inner-vlan`	This parameter is used within double-tagged VLANs. It is the inner VLAN tag (VID); sometimes referred to as the C-TAG (Customer VLAN TAG), where the vlan VID tag is referred to as the S-TAG (Service VLAN TAG).
<1-4094>	The inner VLAN VID.

Mode Global Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicitly match a filter is permitted.

Usage This command creates an access-list for use with hardware classification, such as when applying QoS. The <4000-4699> range MAC hardware access-list will match on packets that have the specified source and destination MAC addresses. You may apply the any parameter if the source or destination MAC host address is not important.

Note Hardware ACLs will permit access unless explicitly denied by an ACL action.

Examples To create an access-list that will permit packets with a MAC address of `0000.00ab.1234` and any destination address enter the commands:

```
awplus# configure terminal
awplus(config)# access-list 4000 permit 0000.00ab.1234
0000.0000.0000 any
```

To create an access-list that will permit packets with an initial MAC address component of `0000.00ab` and any destination address, enter the commands:

```
awplus# configure terminal
awplus(config)# access-list 4001 permit 0000.00ab.1234
0000.0000.FFFF any
```

To create an access-list that will copy-to-mirror packets with an initial MAC address component of `0000.00ab` and any destination address for use with the mirror interface command, enter the commands:

```
awplus# configure terminal
awplus(config)# access-list 4001 copy-to-mirror 0000.00ab.1234
0000.0000.FFFF any
```

To destroy the access-list with an access-list identity of `4000` enter the commands:

```
awplus# configure terminal
awplus(config)# no access-list 4000
```

Related Commands

access-group
mirror interface
show running-config
show access-list (IPv4 Hardware ACLs)

access-list hardware (named)

This command creates a named hardware access-list that can be applied to a switch port interface. ACL filters for a named hardware ACL are created in the IPv4 Hardware ACL Configuration mode.

The no variant of this command removes the specified named hardware ACL.

Syntax

```
access-list hardware <hardware-access-list-name>
no access-list hardware <hardware-access-list-name>
```

Parameter	Description
<hardware-access-list-name>	Specify the hardware ACL name to then define ACL filters for in the subsequent IPv4 Hardware ACL Configuration mode.

Mode Global Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicitly match a filter is permitted.

Usage Use this command to name a hardware ACL and enter the IPv4 Hardware ACL Configuration mode. If the named hardware ACL doesn't exist, it will be created after entry. If the named hardware ACL does exist, then you can enter IPv4 Hardware ACL Configuration mode for that existing ACL.

Entering this command with the hardware ACL name moves you to the `(config-ip-hw-acl)` prompt for the IPv4 Hardware ACL Configuration mode so you can enter ACL filters with sequence numbers. From this prompt, configure the filters for the ACL. See Chapter 55, Access Control Lists Introduction for complete examples of configured sequenced numbered ACLs.

See also the table "IPv4 Hardware Access List Commands and Prompts" in this chapter. This table shows the relevant prompts at which ACL commands and ACL filters are entered for sequenced ACLs.

Note Hardware ACLs will permit access unless explicitly denied by an ACL action.

Example To create the hardware access-list named `ACL-1` and enter the IPv4 Hardware ACL Configuration mode to specify the ACL filter entry, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware ACL-1
awplus(config-ip-hw-acl)#
```

To remove the hardware access-list named `ACL-1`, use the commands:

```
awplus# configure terminal
awplus(config)# no access-list hardware ACL-1
```

Related Commands

access-group
(access-list hardware ICMP filter)
(access-list hardware IP protocol filter)
(access-list hardware TCP UDP filter)
(access-list standard named filter)
show access-group
show access-list (IPv4 Hardware ACLs)

(access-list hardware ICMP filter)

Use this ACL filter to add a new ICMP filter entry to the current hardware access-list. The filter will match on any ICMP packet that has the specified source and destination IP addresses and ICMP type. The parameter any may be specified if an address does not matter and the ICMP type is an optional parameter. If a sequence number is specified, the new filter is inserted at the specified location. Otherwise, the new filter is added at the end of the access-list.

Note that specifying the send-to-cpu parameter could result in EPSR healthcheck messages and other control packets being dropped.

The optional vlan parameter can be applied to match tagged (802.1q) packets.

The no variant of this command removes an ICMP filter entry from the current hardware access-list. You can specify the ICMP filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its ICMP filter profile without specifying its sequence number.

Note that the sequence number can be found by running the command, the show access-list (IPv4 Hardware ACLs) command on page 56.39.

Syntax [icmp]

```
[<sequence-number>]
   {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   icmp <source> <destination>
   [icmp <icmp-value>] [vlan <1-4094>]

no {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   icmp <source> <destination>
   [icmp <icmp-value>] [vlan <1-4094>]

no <sequence-number>
```

Parameter	Description
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.
deny	Access-list rejects packets that match the source and destination filtering specified with this command.
permit	Access-list permits packets that match the source and destination filtering specified with this command.
send-to-cpu	Specify packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.
copy-to-cpu	Specify packets to copy to the CPU.
copy-to-mirror	Specify packets to copy to the mirror port.
icmp	ICMP packet type.

Parameter(cont.)	**Description**(cont.)	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	<ip-addr>/ <prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	<ip-addr> <reverse-mask>	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
	`host` *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	`any`	Matches any source IP address.
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	<ip-addr>/ <prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr> <reverse-mask>	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	`any`	Matches any destination IP address.
`icmp-type`	The ICMP type.	
<icmp-value>	The value of the ICMP type.	
`vlan`	Specifies that the ACL will match on the ID in the packet's VLAN tag.	
<1-4094>	The VLAN VID.	

Mode IPv4 Hardware ACL Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicitly match a filter is permitted.

Usage First create a named hardware access-list that applies the appropriate permit, deny requirements etc. Then use the access-group command on page 56.4 to apply this access-list to a specific port or range. Note that this command will apply the access-list only to incoming data packets.

An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number.

Note

You must reach the prompt `awplus(config-ip-hw-acl)#` by running the access-list hardware (named) command on page 56.19, and entering an appropriate access-list name.

Note

Hardware ACLs will permit access unless explicitly denied by an ACL action.

Example To add an access-list filter entry with a sequence number of `100` to the access-list named `my-list` that will permit ICMP packets with a source address of `192.168.1.0/24`, any destination address and an icmp type of `5`, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware my-list
awplus(config-ip-hw-acl)# 100 permit icmp 192.168.1.0/24 any
icmp-type 5
```

To remove an access-list filter entry with a sequence number of `100` in the access-list named `my-list`, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware my-list
awplus(config-ip-hw-acl)# no 100
```

Related Commands
access-list hardware (named)
show running-config
show access-list (IPv4 Hardware ACLs)

(access-list hardware IP protocol filter)

Use this ACL filter to add an IP protocol type filter entry to the current hardware access-list. The filter will match on any IP packet that has the specified source and destination IP addresses and IP protocol type, or has the optionally specified source and destination MAC addresses. The parameter any may be specified if an address does not matter. If a sequence number is specified, the new filter is inserted at the specified location. Otherwise, the new filter is added at the end of the access-list.

Note that specifying the send-to-cpu parameter could result in EPSR healthcheck messages and other control packets being dropped.

The optional vlan parameter can be applied to match tagged (802.1q) packets.

The no variant of this command removes an IP protocol type filter entry from the current hardware access-list. You can specify the IP protocol type filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its IP protocol type filter profile without specifying its sequence number.

Note that the sequence number can be found by running the show access-list (IPv4 Hardware ACLs) command on page 56.39.

Syntax [ip|proto]

```
[<sequence-number>]
   {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   {ip|any|proto <ip-protocol>}
   {<source>|dhcpsnooping} <destination>
   [mac {<mac-source-address> <mac-source-mask>|any}
   {<mac-destination-address> <mac-destination-mask>|any}]
   [vlan <1-4094>]

no {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   {ip|any|proto <ip-protocol>}
   {<source>|dhcpsnooping} <destination>
   [mac {<mac-source-address> <mac-source-mask>|any}
   {<mac-destination-address> <mac-destination-mask>|any}]
   [vlan <1-4094>]

no <sequence-number>
```

Parameter	Description
`<sequence-number>`	`<1-65535>` The sequence number for the filter entry of the selected access control list.
`deny`	Access-list rejects packets of the type specified.
`permit`	Access-list allows packets of the type specified
`send to cpu`	Specify packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.
`copy to cpu`	Specify packets to copy to the CPU.
`copy to mirror`	Specify packets to copy to the mirror port.
`ip`	IP packets.
`any`	Any packet.

Parameter(cont.)	**Description**(cont.)
`proto <ip-protocol>`	The IP Protocol type specified by it protocol number <1-255>.
`<ip-protocol>`	The IP protocol number, as defined by IANA (Internet Assigned Numbers Authority http://www.iana.org/assignments/protocol-numbers)

Protocol Number	Protocol Description [RFC Reference]
1	Internet Control Message [RFC792]
2	Internet Group Management [RFC1112]
3	Gateway-to-Gateway [RFC823]
4	IP in IP [RFC2003]
5	Stream [RFC1190] [RFC1819]
6	TCP (Transmission Control Protocol) [RFC793]
8	EGP (Exterior Gateway Protocol) [RFC888]
9	IGP (Interior Gateway Protocol) [IANA]
11	Network Voice Protocol [RFC741]
17	UDP (User Datagram Protocol) [RFC768]
20	Host monitoring [RFC869]
27	RDP (Reliable Data Protocol) [RFC908]
28	IRTP (Internet Reliable Transaction Protocol) [RFC938]
29	ISO-TP4 (ISO Transport Protocol Class 4) [RFC905]
30	Bulk Data Transfer Protocol [RFC969]
33	DCCP (Datagram Congestion Control Protocol) [RFC4340]
48	DSR (Dynamic Source Routing Protocol) [RFC4728]
50	ESP (Encap Security Payload) [RFC2406]
51	AH (Authentication Header) [RFC2402]

Parameter(cont.)	**Description**(cont.)	
<ip-protocol> (cont.)	54	NARP (NBMA Address Resolution Protocol) [RFC1735]
	58	ICMP for IPv6 [RFC1883]
	59	No Next Header for IPv6 [RFC1883]
	60	Destination Options for IPv6 [RFC1883]
	88	EIGRP (Enhanced Interior Gateway Routing Protocol)
	89	OSPFIGP [RFC1583]
	97	Ethernet-within-IP Encapsulation / RFC3378

	134	RSVP-E2E-IGNORE / RFC3175
	135	Mobility Header / RFC3775
	136	UDPLite / RFC3828
	137	MPLS-in-IP / RFC4023
	138	MANET Protocols / RFC-ietf-manet-iana-07.txt
	139-252	Unassigned / IANA
	253	Use for experimentation and testing / RFC3692
	254	Use for experimentation and testing / RFC3692
	255	Reserved / IANA
dhcpsnooping	The source address learned from the DHCP Snooping binding database.	

Parameter(cont.)	**Description**(cont.)	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	`any`	Matches any source IP address.
	`host` *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	`any`	Matches any destination IP address.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
`mac`	Signifies a MAC and based hardware access-list.	
<mac-source-address>	The source hosts MAC address, entered in HHHH.HHHH.HHHH format.	
<mac-source-mask>	The source hosts MAC wildcard mask entered in HHHH.HHHH.HHHH format. Where Hex `FF` = Ignore, and Hex `00` = Match.	
`any`	Matches any source MAC address.	
<mac-destination-address>	The destination hosts MAC address, entered in HHHH.HHHH.HHHH format.	

Parameter(cont.)	**Description**(cont.)
<mac-destination-mask>	The destination hosts wildcard mask entered in HHHH.HHHH.HHHH format. Where Hex `FF` = Ignore, and Hex `00` = Match.
`any`	Matches any destination MAC address.
`vlan`	Specifies that the ACL will match on the ID in the packet's VLAN tag.
<1-4094>	The VLAN VID.

Mode IPv4 Hardware ACL Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicitly match a filter is permitted.

Usage First create a named hardware access-list that applies the appropriate permit, deny requirements etc. Then use the access-group command on page 56.4 to apply this access-list to a specific port or range. Note that this command will apply the access-list only to incoming data packets.

An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number.

Note
The access control list being configured is selected by running the access-list hardware (named) command on page 56.19. with the required access control list number, or name, but with no further parameters selected.

Note
Hardware ACLs will permit access unless explicitly denied by an ACL action.

Examples To add an access-list filter entry to the access-list named `my-list` that will permit any type of IP packet with a source address of `192.168.1.1` and any destination address, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware my-list
awplus(config-ip-hw-acl)# permit ip 192.168.1.1/32 any
```

To add an access-list filter entry to the access-list named `my-list` that will permit any type of IP packet with a source address of `192.168.1.1` and a MAC source address of `ffee.ddcc.bbaa` with any IP and MAC destination address, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware my-list
awplus(config-ip-hw-acl)# permit ip 192.168.1.1/32 any mac
ffee.ddcc.bbaa any
```

To add an access-list filter entry to the access-list named `my-list` a filter that will deny all IGMP packets (protocol `2`) from the `192.168.0.0` network with sequence number `50` in access-list, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware my-list
awplus(config-ip-hw-acl)# 50 deny proto 2 192.168.0.0/16 any
```

To add an access-list filter entry to the access-list named `my-list` that will deny all IP packets on vlan `2`, use the commands:

```
awplus# ena
awplus(config)# configure terminal
awplus(config)# access-list hardware my-list
awplus(config-ip-hw-acl)# deny ip any any vlan 2
```

Related Commands

access-list hardware (named)
show running-config
show access-list (IPv4 Hardware ACLs)

(access-list hardware MAC filter)

Use this ACL filter to add a MAC filter entry to the current hardware access-list. The filter will match on any IP packet that has the specified source and destination MAC addresses. The parameter any may be specified if an address does not matter. If a sequence number is specified, the new filter is inserted at the specified location. Otherwise, the new filter is added at the end of the access-list.

Note that specifying the send-to-cpu parameter could result in EPSR healthcheck messages and other control packets being dropped.

Optionally, the vlan and inner-vlan parameters can be matched for tagged (802.1q) packets.

The no variant of this command removes a MAC filter entry from the current hardware access-list. You can specify the MAC filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its MAC filter profile without specifying its sequence number.

Note that the sequence number can be found by running the show access-list (IPv4 Hardware ACLs) command on page 56.39.

Syntax [mac]

```
[<sequence-number>]
   {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   mac {<source-mac-address> <source-mac-mask>|any}
   {<destination-mac-address> <destination-mac-mask>|any}
   [{vlan <1-4094>|inner-vlan <1-4094>}]

no {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   mac {<source-mac-address> <source-mac-mask>|any}
   {<destination-mac-address> <destination-mac-mask>|any}
   [{vlan <1-4094>|inner-vlan <1-4094>}]

no <sequence-number>
```

Parameter	Description
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.
deny	Specify packets to reject.
permit	Specify packets to accept.
send-to-cpu	Specify packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.
copy-to-cpu	Specify packets to copy to the CPU.
copy-to-mirror	Specify packets to copy to the CPU.
mac	MAC address.
<source-mac-address>	The source MAC address of the packets. Enter this in the format <HHHH.HHHH.HHHH> Where each H is a hexadecimal number that represents a 4 bit binary number.

Parameter(cont.)	Description(cont.)
<source-mac-mask	The mask that will be applied to the source MAC addresses. Enter this in the format <HHHH.HHHH.HHHH> Where each H is a hexadecimal number that represents a 4 bit binary number. For a mask, each value will be either `0` or `F`. Where Hex `FF` = Ignore, and Hex `00` = Match.
`any`	Any source MAC host.
<destination-mac-address>	The destination MAC address of the packets. Enter this in the format <HHHH.HHHH.HHHH> Where each H is a hexadecimal number that represents a 4 bit binary number.
<destination-mac-mask>	The mask that will be applied to the destination MAC addresses. Enter this in the format <HHHH.HHHH.HHHH> Where each H is a hexadecimal number that represents a 4 bit binary number. For a mask, each value will be either `0` or `F`. Where Hex `FF` = Ignore, and Hex `00` = Match.
`any`	Any destination MAC host.
`vlan`	Specifies that the ACL will match on the ID in the packet's VLAN tag.
<1-4094>	The VLAN VID.
`inner-vlan`	This parameter is used within double-tagged VLANs. It is the inner VLAN tag (VID); sometimes referred to as the C-TAG (Customer VLAN TAG), where the vlan VID tag is referred to as the S-TAG (Service VLAN TAG).
<1-4094>	The inner VLAN VID.

Mode IPv4 Hardware ACL Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicitly match a filter is permitted.

Usage First create a named hardware access-list that applies the appropriate permit, deny requirements etc. Then use the access-group command on page 56.4 to apply this access-list to a specific port or range. Note that this command will apply the access-list only to incoming data packets.

An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number

Note

The access control list being configured is selected by running the access-list hardware (named) command on page 56.19. with the required access control list number, or name, but with no further parameters selected.

Note Hardware ACLs will permit access unless explicitly denied by an ACL action.

Example To add an access-list filter entry to the access-list named `my-list` that will permit packets with a source MAC address of `0000.00ab.1234` and any destination MAC address, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware my-list
awplus(config-ip-hw-acl)# permit mac 0000.00ab.1234
0000.0000.0000 any
```

Example To remove an access-list filter entry that permit packets with a source MAC address of `0000.00ab.1234` and any destination MAC address, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware my-list
awplus(config-ip-hw-acl)# no permit mac 0000.00ab.1234
0000.0000.0000 any
```

Related Commands
access-group
access-list hardware (named)
show running-config

(access-list hardware TCP UDP filter)

Use this ACL filter to add a TCP or UDP filter entry to the current hardware access-list. The filter will match on any TCP or UDP type packet that has the specified source and destination IP addresses. The parameter any may be specified if an address does not matter. If a sequence number is specified, the new filter is inserted at the specified location. Otherwise, the new filter is added at the end of the access-list.

Note that specifying the send-to-cpu parameter could result in EPSR healthcheck messages and other control packets being dropped.

The optional vlan parameter can be applied to match tagged (802.1q) packets.

The no variant of this command removes a TCP or UDP filter entry from the current hardware access-list. You can specify the TCP or UDP filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its TCP or UDP filter profile without specifying its sequence number.

Note that the sequence number can be found by running the show access-list (IPv4 Hardware ACLs) command on page 56.39.

Syntax [tcp|udp]

```
[<sequence-number>]
   {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   {tcp|udp}
   [<source>|
   eq <sourceport>|gt <sourceport>|lt <sourceport>|
   ne <sourceport>|range <start-range> <end-range>]
   [<destination>|
   eq <destport>|gt <destport>|lt <destport>|
   ne <destport>|range <start-range> <end-range>]
   [vlan <1-4094>]

no {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   {tcp|udp}
   [<source>|
   eq <sourceport>|gt <sourceport>|lt <sourceport>|
   ne <sourceport>|range <start-range> <end-range>]
   [<destination>|
   eq <destport>|gt <destport>|lt <destport>|
   ne <destport>|range <start-range> <end-range>]
   [vlan <1-4094>]

no <sequence-number>
```

Parameter	Description
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.
deny	Access-list rejects packets that match the source and destination filtering specified with this command.
permit	Access-list permits packets that match the source and destination filtering specified with this command.
send-to-cpu	Specify packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.
copy-to-cpu	Specify packets to copy to the CPU.

Parameter(cont.)	**Description**(cont.)	
`copy-to-mirror`	Specify packets to copy to the mirror port.	
`tcp`	TCP packets.	
`udp`	UDP packets.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	`any`	Matches any source IP address.
	`host` *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	<ip-addr> <reverse-mask>	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
<sourceport>	The source TCP or UDP port number, specified as an integer between 0 and 65535.	
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	`any`	Matches any destination IP address.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr> <reverse-mask>	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
`eq`	Equal to.	

Parameter(cont.)	**Description**(cont.)
`lt`	Less than.
`gt`	Greater than.
`ne`	Not equal to.
<destport>	The source TCP or UDP port number, specified as an integer between 0 and 65535.
`range`	Specify the range of port numbers between 0 and 65535.
<start-range>	The source or destination port number at the start of the range *<0-65535>*.
<end-range>	The source or destination port number at the end of the range *<0-65535>*.
`vlan`	Specifies that the ACL will match on the ID in the packet's VLAN tag.
<1-4094>	The VLAN VID.

Mode IPv4 Hardware ACL Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicitly match a filter is permitted.

Usage First create a named hardware access-list that applies the appropriate permit, deny requirements etc. Then use the access-group command on page 56.4 to apply this access-list to a specific port or range. Note that this command will apply the access-list only to incoming data packets.

An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number.

Note
The access control list being configured is selected by running the access-list hardware (named) command on page 56.19. with the required access control list number, or name, but with no further parameters selected.

Note
Hardware ACLs will permit access unless explicitly denied by an ACL action.

Example To add an access-list filter entry to access-list named `my-hw-list` that will permit TCP packets with a destination address of `192.168.1.1`, a destination port of `80`, and any source address, and source port, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware my-hw-list
awplus(config-ip-hw-acl)# permit tcp any 192.168.1.1/32 eq 80
```

Related Commands

access-list hardware (named)
show running-config
show access-list (IPv4 Hardware ACLs)

commit (IPv4)

Use this command to commit the ACL filter configuration to hardware immediately without exiting Hardware ACL Configuration mode.

Syntax `commit`

Mode IPv4 Hardware ACL Configuration

Usage Normally, when a hardware ACL is edited, the new configuration state of the ACL is not written to hardware until you exit Hardware ACL Configuration mode. By entering this command you can ensure that the current state of a hardware access-list that is being edited is written to hardware immediately.

Scripts typically do not include the exit command to exit configuration modes, potentially leading to ACL filters in hardware not being correctly updated. Using this commit command in a configuration script after specifying a hardware ACL filter ensures that it is updated in the hardware.

Examples To update the hardware with the ACL filter configuration, use the command:

```
awplus# configure terminal
awplus(config)# access-list hardware my-hw-list
awplus(config-ip-hw-acl)# commit
```

Related Commands access-list hardware (named)

show access-group

Use this command to show the access-lists attached globally. If an access-list is specified, only that access-list will be displayed.

Syntax `show access-group [{<3000-3699>|<4000-4699>|<access-list-name>}]`

Parameter	Description
<3000-3699>	Specify a Hardware IP access-list.
<4000-4699>	Specify a Hardware MAC access-list.
<access-list-name>	Specify a Hardware IPv4 access-list name.

Mode User Exec and Privileged Exec

Example To show all access-lists attached globally:

```
awplus# show access-group
```

Output Figure 56-1: Example output from the **show access-group** command

```
Global access control list
access-group 3000
access-group 4000
```

Related Commands ip prefix-list

show access-list (IPv4 Hardware ACLs)

Use this command to display the specified access-list, or all access-lists if none have been specified. Note that only defined access-lists are displayed. An error message is displayed for an undefined access-list.

Syntax

```
show access-list
    [<1-99>|<100-199>|<1300-1999>|<2000-2699>|<3000-3699>|
    <4000-4499>|<access-list-name>]
```

Parameter	Description
<1-99>	IP standard access-list.
<100-199>	IP extended access-list.
<1300-1999>	IP standard access-list (standard - expanded range).
<2000-2699>	IP extended access-list (extended - expanded range).
<3000-3699>	Hardware IP access-list.
<4000-4499>	Hardware MAC access-list.
<access-list-name>	IP named access-list.

Mode User Exec and Privileged Exec

Example To show all access-lists configured on the switch:

```
awplus# show access-list
```

```
Standard IP access list 1
    deny 172.16.2.0, wildcard bits 0.0.0.255
Standard IP access list 20
    deny 192.168.10.0, wildcard bits 0.0.0.255
    deny 192.168.12.0, wildcard bits 0.0.0.255
Hardware IP access list 3001
    permit ip 192.168.20.0 255.255.255.0 any
Hardware IP access list 3020
    permit tcp any 192.0.2.0/24
awplus#show access-list 20
```

Example To show the access-list with an ID of 20:

```
awplus# show access-list 20
```

```
Standard IP access-list 20
    deny 192.168.10.0, wildcard bits 0.0.0.255
    deny 192.168.12.0, wildcard bits 0.0.0.255
```

Note the below error message if you attempt to show an undefined access-list:

```
awplus# show access-list 2
```

```
% Can't find access-list 2
```

Related Commands

access-list extended (named)
access-list (hardware MAC numbered)
access-list hardware (named)

show interface access-group

Use this command to display the access groups attached to a port. If an access group is specified, then the output only includes the ports that the specified access group is attached to. If no access group is specified then this command displays all access groups that are attached to the ports that are specified with *<port-list>*.

Note that access group is the term given for an access-list when it is applied to an interface.

Syntax

```
show interface <port-list> access-group
    [<3000-3699>|<4000-4699>|<access-list-name>]
```

Parameter	Description
<port-list>	Specify the ports to display information. A port-list can be either: ■ a switch port (e.g. port1.0.12) a static channel group (e.g., sa3) or a dynamic (LACP) channel group (e.g., po3) ■ a continuous range of ports separated by a hyphen, e.g., port1.0.1-1.0.24 or port1.0.1-port1.0.24 or po1-po4 ■ a comma-separated list of ports and port ranges, e.g. port1.0.1,port1.0.3-1.0.24. Do not mix switch ports, static channel groups, and LACP channel groups in the same list.
`access group`	Select the access group whose details you want to show.
<3000-3699>	Specifies the Hardware IP access-list.
<4000-4699>	Specifies the Hardware MAC access-list.
<access-list-name>	Specify the Hardware IPv6 access-list name.

Mode User Exec and Privileged Exec

Example To show all access-lists attached to `port1.0.1`, use the command:

```
awplus# show interface port1.0.1 access-group
```

Output Figure 56-2: Example output from the **show interface access-group** command

```
Interface port1.0.1
  access-group 3000
  access-group 3002
  access-group 3001
```

Introduction

This chapter provides an alphabetical reference for the IPv4 Software Access Control List (ACL) commands, and contains detailed command information and command examples about IPv4 software ACLs as applied to Routing and Multicasting, which are not applied to interfaces.

Note

See Chapter 55, Access Control Lists Introduction for descriptions of ACLs, and for further information about rules when applying ACLs see the ACL Rules section.

See ACL Filter Sequence Numbers and ACL Filter Sequence Number Behavior sections in Chapter 55, Access Control Lists Introduction about ACL Filters.

See all relevant Routing commands and configurations in "IPv4 Software Access Control List (ACL) Commands" and all relevant Multicast commands and configurations in "Multicast Applications".

To apply ACLs to an LACP channel group, apply it to all the individual switch ports in the channel group. To apply ACLs to a static channel group, apply it to the static channel group itself. For more information on link aggregation see Chapter 20, Link Aggregation Introduction and Configuration, and Chapter 21, Link Aggregation Commands.

Note

Text in parenthesis in command names indicates usage not keyword entry. For example, access-list hardware (named) indicates named IPv4 hardware ACLs entered as `access-list hardware` <*name*> where <*name*> is a placeholder not a keyword.

Note

Parenthesis surrounding ACL filters indicates the type of ACL filter not the keyword entry in the CLI, such as (access-list standard numbered filter) represents command entry in the format shown in the syntax `[<sequence-number>] {deny|permit} {<source>|host <host-address>|any}`.

Note

Software ACLs will deny access unless explicitly permitted by an ACL action.

IPv4 Software Access List Commands and Prompts

Many of the ACL commands operate from sub-modes that are specific to particular ACL types. The table "IPv4 Software Access List Commands and Prompts" shows the CLI prompts at which ACL commands are entered.

Table 57-1: IPv4 Software Access List Commands and Prompts

Command Name	Command Mode	Prompt
clear ip prefix-list	Privileged Exec	awplus#
show ip access-list	Privileged Exec	awplus#
show ip prefix-list	Privileged Exec	awplus#
access-group	Global Configuration	awplus(config)#
access-list (extended numbered)	Global Configuration	awplus(config)#
access-list standard (named)	Global Configuration	awplus(config)#
access-list (standard numbered)	Global Configuration	awplus(config)#
ip prefix-list	Global Configuration	awplus(config)#
maximum-access-list	Global Configuration	awplus(config)#
(access-list extended ICMP filter)	IPv4 Extended ACL Configuration	awplus(config-ip-ext-acl)#
(access-list extended IP filter)	IPv4 Extended ACL Configuration	awplus(config-ip-ext-acl)#
(access-list extended IP protocol filter)	IPv4 Extended ACL Configuration	awplus(config-ip-ext-acl)#
(access-list extended TCP UDP filter)	IPv4 Extended ACL Configuration	awplus(config-ip-ext-acl)#
(access-list standard named filter)	IPv4 Standard ACL Configuration	awplus(config-ip-std-acl)#
(access-list standard numbered filter)	IPv4 Standard ACL Configuration	awplus(config-ip-std-acl)#

Command List

access-list extended (named)

This command configures an extended named access-list that permits or denies packets from specific source and destination IP addresses. You can either create an extended named ACL together with an ACL filter entry in the Global Configuration mode, or you can use the IPv4 Extended ACL Configuration mode for sequenced ACL filter entry after entering a list name.

The no variant of this command removes a specified extended named access-list.

Syntax [list-name]

```
access-list extended <list-name>

no access-list extended <list-name>
```

Parameter	Description
<list-name>	A user-defined name for the access-list

Syntax [icmp]

```
access-list extended <list-name>
    {deny|permit}
    icmp <source> <destination>
    [icmp-type <type-number>]
    [log]

no access-list extended <list-name>
    {deny|permit}
    icmp <source> <destination>
    [icmp-type <type-number>]
    [log]
```

Table 57-2: Parameters in the access-list extended (named) command - icmp

Parameter	Description
<list-name>	A user-defined name for the access-list.
`deny`	The access-list rejects packets that match the type, source, and destination filtering specified with this command.
`permit`	The access-list permits packets that match the type, source, and destination filtering specified with this command.
`icmp`	The access-list matches only ICMP packets.
`icmp-type`	Matches only a specified type of ICMP messages. This is valid only when the filtering is set to match ICMP packets.

Table 57-2: Parameters in the access-list extended (named) command - icmp(cont.)

Parameter(cont.)	**Description**(cont.)	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	`any`	Matches any source IP address.
	`host` *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	`any`	Matches any destination IP address.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.

Table 57-2: Parameters in the access-list extended (named) command - icmp(cont.)

Parameter(cont.)	**Description**(cont.)	
<type-number>	The ICMP type, as defined in RFC792 and RFC950. Specify one of the following integers to create a filter for the ICMP message type:	
	0	Echo replies.
	3	Destination unreachable messages.
	4	Source quench messages.
	5	Redirect (change route) messages.
	8	Echo requests.
	11	Time exceeded messages.
	12	Parameter problem messages.
	13	Timestamp requests.
	14	Timestamp replies.
	15	Information requests.
	16	Information replies.
	17	Address mask requests.
	18	Address mask replies.
log	Logs the results.	

Syntax [tcp|udp]

```
access-list extended <list-name>
    {deny|permit}
    {tcp|udp}
    <source>
    [eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>]
    <destination>
    [eq <destport>|lt <destport>|gt <destport>|ne <destport>]
    [log]]

no access-list extended <list-name>
    {deny|permit}
    {tcp|udp}
    <source>
    [eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>]
    <destination>
    [eq <destport>|lt <destport>|gt <destport>|ne <destport>]
    [log]]
```

Table 57-3: Parameters in the access-list extended (named) command - tcp|udp

Parameter	Description	
<list-name>	A user-defined name for the access-list.	
deny	The access-list rejects packets that match the type, source, and destination filtering specified with this command.	
permit	The access-list permits packets that match the type, source, and destination filtering specified with this command.	
tcp	The access-list matches only TCP packets.	
udp	The access-list matches only UDP packets.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	any	Matches any source IP address.
	host *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	<ip-addr> <reverse-mask>	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.

Table 57-3: Parameters in the access-list extended (named) command - tcp|udp(cont.)

Parameter(cont.)	**Description**(cont.)	
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	`any`	Matches any destination IP address.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/ *<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
<sourceport>	The source port number, specified as an integer between 0 and 65535.	
<destport>	The destination port number, specified as an integer between 0 and 65535.	
`eq`	Matches port numbers equal to the port number specified immediately after this parameter.	
`lt`	Matches port numbers less than the port number specified immediately after this parameter.	
`gt`	Matches port numbers greater than the port number specified immediately after this parameter.	
`ne`	Matches port numbers not equal to the port number specified immediately after this parameter.	
`log`	Log the results.	

Syntax [proto|any|ip]

```
access-list extended <list-name>
    {deny|permit}
    {proto <ip-protocol>|any|ip}
    {<source>}
    {<destination>}
    [log]

no access-list extended <list-name>
    {deny|permit}
    {proto <ip-protocol>|any|ip}
    {<source>}
    {<destination>}
    [log]
```

Table 57-4: Parameters in the access-list extended (named) command - proto|ip|any

Parameter	Description	
<list-name>	A user-defined name for the access-list.	
deny	The access-list rejects packets that match the type, source, and destination filtering specified with this command.	
permit	The access-list permits packets that match the type, source, and destination filtering specified with this command.	
proto	Matches only a specified type of IP Protocol.	
any	The access-list matches any type of IP packet.	
ip	The access-list matches only IP packets.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	any	Matches any source IP address.
	host *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering 192.168.1.1 0.0.0.255 is the same as entering 192.168.1.1/24.

Table 57-4: Parameters in the access-list extended (named) command - proto|ip|any(cont.)

Parameter(cont.)	Description(cont.)	
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	`any`	Matches any destination IP address.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr>/*<prefix>*	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr> *<reverse-mask>*	Alternatively, you can enter a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
`log`	Logs the results.	
<ip-protocol>	The IP protocol number, as defined by IANA (Internet Assigned Numbers Authority http://www.iana.org/assignments/protocol-numbers)	
	Protocol Number	**Protocol Description [RFC Reference]**
	`1`	Internet Control Message [RFC792]
	`2`	Internet Group Management [RFC1112]
	`3`	Gateway-to-Gateway [RFC823]
	`4`	IP in IP [RFC2003]
	`5`	Stream [RFC1190] [RFC1819]
	`6`	TCP (Transmission Control Protocol) [RFC793]
	`8`	EGP (Exterior Gateway Protocol) [RFC888]
	`9`	IGP (Interior Gateway Protocol) [IANA]
	`11`	Network Voice Protocol [RFC741]
	`17`	UDP (User Datagram Protocol) [RFC768]
	`20`	Host monitoring [RFC869]
	`27`	RDP (Reliable Data Protocol) [RFC908]
	`28`	IRTP (Internet Reliable Transaction Protocol) [RFC938]
	`29`	ISO-TP4 (ISO Transport Protocol Class 4) [RFC905]
	`30`	Bulk Data Transfer Protocol [RFC969]

Table 57-4: Parameters in the access-list extended (named) command - proto|ip|any(cont.)

Parameter(cont.)	Description(cont.)	
<ip-protocol> (cont.)	**Protocol Number**	**Protocol Description [RFC Reference]**
	33	Datagram Congestion Control Protocol [RFC4340]
	48	DSR (Dynamic Source Routing Protocol) [RFC4728]
	50	ESP (Encap Security Payload) [RFC2406]
	51	AH (Authentication Header) [RFC2402]
	54	NARP (NBMA Address Resolution Protocol) [RFC1735]
	88	EIGRP (Enhanced Interior Gateway Routing Protocol)
	89	OSPFIGP [RFC1583]
	97	Ethernet-within-IP Encapsulation / RFC3378
	98	Encapsulation Header / RFC1241
	108	IP Payload Compression Protocol / RFC2393
	112	Virtual Router Redundancy Protocol / RFC3768
	134	RSVP-E2E-IGNORE / RFC3175
	135	Mobility Header / RFC3775
	136	UDPLite / RFC3828
	137	MPLS-in-IP / RFC4023
	138	MANET Protocols / RFC-ietf-manet-iana-07.txt
	139-252	Unassigned / IANA
	253	Use for experimentation and testing / RFC3692
	254	Use for experimentation and testing / RFC3692
	255	Reserved / IANA

Mode Global Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage Use this command when configuring access-list for filtering IP software packets. To enable backwards compatibility you can either create access-lists from within this command, or you can enter access-list followed by only the number. This latter method moves you to the IPv4 Extended ACL Configuration mode for the selected access-list number, and from here you can configure your access-lists by using the commands (access-list extended ICMP filter), (access-list extended IP filter), and (access-list extended IP protocol filter).

The table "IPv4 Software Access List Commands and Prompts" on page 57.3 shows the prompts at which ACL commands are entered. See the relevant links shown for the Related Commands.

Note that packets must match both the source and the destination details.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Example You can enter the extended named ACL in the Global Configuration mode together with the ACL filter entry on the same line, as in previous software releases as shown below:

```
awplus# configure terminal
awplus(config)# access-list extended TK deny tcp 2.2.2.3/24 eq
14 3.3.3.4/24 lt 12 log
```

Alternatively, you can enter the extended named ACL in Global Configuration mode before specifying the ACL filter entry in the IPv4 Extended ACL Configuration mode, as shown below:

```
awplus# configure terminal
awplus(config)# access-list extended TK
awplus(config-ip-ext-acl)# deny tcp 2.2.2.3/24 eq 14 3.3.3.4/24
lt 12 log
```

Related Commands
(access-list extended ICMP filter)
(access-list extended IP filter)
(access-list extended TCP UDP filter)
show access-group
show running-config
show ip access-list

access-list (extended numbered)

This command configures an extended numbered access-list that permits or denies packets from specific source and destination IP addresses. You can either create an extended numbered ACL together with an ACL filter entry in the Global Configuration mode, or you can use the IPv4 Extended ACL Configuration mode for sequenced ACL filter entry after entering a list number.

The no variant of this command removes a specified extended named access-list.

Syntax [list-number]

```
access-list {<100-199>|<2000-2699>}

no access-list {<100-199>|<2000-2699>}
```

Parameter	Description
<100-199>	IP extended access-list.
<2000-2699>	IP extended access-list (expanded range).

Syntax [deny|permit]

```
access-list {<100-199>|<2000-2699>}
   {deny|permit}
   ip <source> <destination>

no access-list {<100-199>|<2000-2699>}
   {deny|permit}
   ip <source> <destination>
```

Parameter	Description	
<100-199>	IP extended access-list.	
<2000-2699>	IP extended access-list (expanded range).	
deny	Access-list rejects packets that match the source and destination filtering specified with this command.	
permit	Access-list permits packets that match the source and destination filtering specified with this command.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	any	Matches any source IP address.
	host *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr> *<reverse-mask>*	An IPv4 address, followed by a reverse mask in dotted decimal format. For example, entering 192.168.1.1 0.0.0.255 is the same as entering 192.168.1.1/24. This matches any source IP address within the specified subnet.
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	

Parameter(cont.)	**Description**(cont.)	
	`any`	Matches any destination IP address.
	`host <ip-addr>`	Matches a single destination host with the IP address given by `<ip-addr>` in dotted decimal notation.
	`<ip-addr> <reverse-mask>`	An IPv4 address, followed by a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`. This matches any destination IP address within the specified subnet.

Mode Global Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage Use this command when configuring access-list for filtering IP software packets. To enable backwards compatibility you can either create access-lists from within this command, or you can enter access-list followed by only the number. This latter method moves you to the IPv4 Extended ACL Configuration mode for the selected access-list number, and from here you can configure your access-lists by using the commands (access-list extended ICMP filter), (access-list extended IP filter), and (access-list extended IP protocol filter).

The table "IPv4 Software Access List Commands and Prompts" on page 57.3 shows the prompts at which ACL commands are entered. See the relevant links shown for the Related Commands.

Note that packets must match both the source and the destination details.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Example You can enter the extended named ACL in the Global Configuration mode together with the ACL filter entry on the same line, as in previous software releases as shown below:

```
awplus# configure terminal
awplus(config)# access-list 101 deny ip 172.16.10.0 0.0.0.255
any
```

Alternatively, you can enter the extended named ACL in Global Configuration mode before specifying the ACL filter entry in the IPv4 Extended ACL Configuration mode, as shown below:

```
awplus# configure terminal
awplus(config)# access-list 101
awplus(config-ip-ext-acl)# deny ip 172.16.10.0 0.0.0.255 any
```

Related Commands

(access-list extended ICMP filter)
(access-list extended IP filter)
(access-list extended TCP UDP filter)
show access-group
show running-config
show ip access-list

(access-list extended ICMP filter)

Use this ACL filter to add a new ICMP filter entry to the current extended access-list. If the sequence number is specified, the new filter is inserted at the specified location. Otherwise, the new filter is added at the end of the access-list.

The no variant of this command removes an ICMP filter entry from the current extended access-list. You can specify the ICMP filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its ICMP filter profile without specifying its sequence number.

Note that the sequence number can be found by running the show access-list (IPv4 Software ACLs) command.

Syntax [icmp]

```
[<sequence-number>] {deny|permit}
    icmp <source> <destination>
    [icmp-type <icmp-value>] [log]

no {deny|permit} icmp <source> <destination>
    [icmp-type <icmp-value>] [log]

no <sequence-number>
```

Parameter	Description	
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.	
deny	Access-list rejects packets that match the source and destination filtering specified with this command.	
permit	Access-list permits packets that match the source and destination filtering specified with this command.	
icmp	ICMP packet type.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	any	Matches any source IP address.
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	any	Matches any destination IP address.
icmp-type	The ICMP type.	

Parameter(cont.)	Description(cont.)
<icmp-value>	The value of the ICMP type.
log	Log the results.

Mode IPv4 Extended ACL Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number.

Note
The access control list being configured is selected by running the access-list (extended numbered) command or the access-list extended (named) command, with the required access control list number, or name - but with no further parameters selected.

Note
Software ACLs will deny access unless explicitly permitted by an ACL action.

Examples To add a new entry in access-list called `my-list` that will reject ICMP packets from `10.0.0.1` to `192.168.1.1`, use the commands:

```
awplus# configure terminal
awplus(config)# access-list extended my-list
awplus(config-ip-ext-acl)# deny icmp 10.0.0.1/32 192.168.1.1/32
```

Use the following commands to add a new filter at sequence number `5` position of the access-list called `my-list`. The filter will accept the ICMP type `8` packets from `10.1.1.0/24` network, to `192.168.1.0` network:

```
awplus# configure terminal
awplus(config)# access-list extended my-list
awplus(config-ip-ext-acl)# 5 permit icmp 10.1.1.0/24
                           192.168.1.0/24 icmp-type 8
```

Related Commands
access-group
show access-group
show running-config
show ip access-list

(access-list extended IP filter)

Use this ACL filter to add a new IP filter entry to the current extended access-list. If the sequence number is specified, the new filter is inserted at the specified location. Otherwise, the new filter is added at the end of the access-list.

The no variant of this command removes an IP filter entry from the current extended access-list. You can specify the IP filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its IP filter profile without specifying its sequence number.

Note that the sequence number can be found by running the show access-list (IPv4 Software ACLs) command.

Syntax [ip]

```
[<sequence-number>] {deny|permit} ip <source> <destination>
no {deny|permit} ip <source> <destination>
no <sequence-number>
```

Parameter	Description	
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.	
`deny`	Access-list rejects packets that match the source and destination filtering specified with this command.	
`permit`	Access-list permits packets that match the source and destination filtering specified with this command.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	`any`	Matches any source IP address.
	`host` *<ip-addr>*	Matches a single source host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr> *<reverse-mask>*	Alternatively, enter an IPv4 address followed by a reverse mask in dotted decimal format. For example, enter `192.168.1.1 0.0.0.255`.
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	`any`	Matches any destination IP address.
	`host` *<ip-addr>*	Matches a single destination host with the IP address given by *<ip-addr>* in dotted decimal notation.
	<ip-addr> *<reverse-mask>*	Alternatively, enter an IPv4 address followed by a reverse mask in dotted decimal format. For example, enter `192.168.1.1 0.0.0.255`.

Mode Extended ACL Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number.

Note

The access control list being configured is selected by running the access-list (extended numbered) command or the access-list extended (named) command, with the required access control list number, or name - but with no further parameters selected.

Note

Software ACLs will deny access unless explicitly permitted by an ACL action.

Example 1 [list-number] First use the following commands to enter the IPv4 Extended ACL Configuration mode and define a numbered extended access-list `101`:

```
awplus# configure terminal
awplus(config)# access-list 101
awplus(config-ip-ext-acl)#
```

Then use the following commands to add a new entry to the numbered extended access-list `101` that will reject packets from `10.0.0.1` to `192.168.1.1`:

```
awplus(config-ip-ext-acl)# deny ip host 10.0.0.1 host
                           192.168.1.1
awplus(config-ip-ext-acl)# 20 permit ip any any
```

Example 2 [list-name] First use the following commands to enter the IPv4 Extended ACL Configuration mode and define a named access-list called `my-acl`:

```
awplus# configure terminal
awplus(config)# access-list extended my-acl
awplus(config-ip-ext-acl)#
```

Then use the following commands to add a new entry to the named access-list `my-acl` that will reject packets from `10.0.0.1` to `192.168.1.1`:

```
awplus(config-ip-ext-acl)# deny ip host 10.0.0.1 host
                           192.168.1.1
awplus(config-ip-ext-acl)# 20 permit ip any any
```

Example 3 [list-number] Use the following commands to remove the access-list filter entry with sequence number `20` from extended numbered access-list `101`.

```
awplus# configure terminal
awplus(config)# access-list 101
awplus(config-ip-ext-acl)# no 20
```

Example 4 [list-name] Use the following commands to remove the access-list filter entry with sequence number `20` from extended named access-list `my-acl`:

```
awplus# configure terminal
awplus(config)# access-list extended my-acl
awplus(config-ip-ext-acl)# no 20
```

Related Commands

access-list extended (named)
access-list (extended numbered)
show access-group
show running-config
show ip access-list

(access-list extended IP protocol filter)

Use this ACL filter to add a new IP protocol type filter entry to the current extended access-list. If the sequence number is specified, the new filter is inserted at the specified location. Otherwise, the new filter is added at the end of the access-list.

The no variant of this command removes an IP protocol filter entry from the current extended access-list. You can specify the IP filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its IP filter profile without specifying its sequence number.

Note that the sequence number can be found by running the show access-list (IPv4 Software ACLs) command.

Syntax [proto]

```
[<sequence-number>] {deny|permit} proto <ip-protocol>
   <source> <destination> [log]

no {deny|permit} proto <ip-protocol> <source> <destination> [log]

no <sequence-number>
```

Parameter	Description
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.
deny	Access-list rejects packets that match the source and destination filtering specified with this command.
permit	Access-list permits packets that match the source and destination filtering specified with this command.
proto *<ip-protocol>*	The IP Protocol type specified by its protocol number <1-255>.
<ip-protocol>	The IP protocol number, as defined by IANA (Internet Assigned Numbers Authority http://www.iana.org/assignments/protocol-numbers).

Protocol Number	Protocol Description [RFC Reference]
1	Internet Control Message [RFC792]
2	Internet Group Management [RFC1112]
3	Gateway-to-Gateway [RFC823]
4	IP in IP [RFC2003]
5	Stream [RFC1190] [RFC1819]
6	TCP (Transmission Control Protocol) [RFC793]
8	EGP (Exterior Gateway Protocol) [RFC888]
9	IGP (Interior Gateway Protocol) [IANA]
11	Network Voice Protocol [RFC741]

Parameter(cont.)	**Description**(cont.)	
<ip-protocol> (cont.)	17	UDP (User Datagram Protocol) [RFC768]
	20	Host monitoring [RFC869]
	27	RDP (Reliable Data Protocol) [RFC908]
	28	IRTP (Internet Reliable Transaction Protocol) [RFC938]
	29	ISO-TP4 (ISO Transport Protocol Class 4) [RFC905]
	30	Bulk Data Transfer Protocol [RFC969]
	33	DCCP (Datagram Congestion Control Protocol) [RFC4340]

	51	AH (Authentication Header) [RFC2402]
	54	NARP (NBMA Address Resolution Protocol) [RFC1735]
	88	EIGRP (Enhanced Interior Gateway Routing Protocol)
	89	OSPFIGP [RFC1583]
	97	Ethernet-within-IP Encapsulation / RFC3378
	98	Encapsulation Header / RFC1241
	108	IP Payload Compression Protocol / RFC2393
	112	Virtual Router Redundancy Protocol / RFC3768
	134	RSVP-E2E-IGNORE / RFC3175
	135	Mobility Header / RFC3775
	136	UDPLite / RFC3828
	137	MPLS-in-IP / RFC4023
	138	MANET Protocols / RFC-ietf-manet-iana-07.txt
	139-252	Unassigned / IANA
	253	Use for experimentation and testing / RFC3692
	254	Use for experimentation and testing / RFC3692
	255	Reserved / IANA

Parameter(cont.)	**Description**(cont.)	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	`any`	Matches any source IP address.
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	`any`	Matches any destination IP address.
`log`	Log the results.	

Mode IPv4 Extended ACL Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number.

Note The access control list being configured is selected by running the access-list (extended numbered) command or the access-list extended (named) command, with the required access control list number, or name - but with no further parameters selected.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Example 1 [creating a list] Use the following commands to add a new access-list filter entry to the access-list named `my-list` that will reject IP packets from source address `10.10.1.1/32` to destination address `192.68.1.1/32`:

```
awplus# configure terminal
awplus(config)# access-list extended my-list
awplus(config-ip-ext-acl)# deny ip 10.10.1.1/32 192.168.1.1/32
```

Example 2 [adding to a list]

Use the following commands to add a new access-list filter entry at sequence position `5` in the access-list named `my-list` that will accept packets from source address `10.10.1.1/24` to destination address `192.68.1.1/24`:

```
awplus# configure terminal
awplus(config)# access-list extended my-list
awplus(config-ip-ext-acl)# 5 permit ip 10.10.1.1/24 192.168.1.1/
24
```

Related Commands

access-list extended (named)
access-list (extended numbered)
show access-group
show running-config
show ip access-list

(access-list extended TCP UDP filter)

Use this ACL filter to add a new TCP or UDP filter entry to the current extended access-list. If the sequence number is specified, the new filter is inserted at the specified location. Otherwise, the new filter is added at the end of the access-list.

The no variant of this command removes a TCP or UDP filter entry from the current extended access-list. You can specify the TCP or UDP filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its TCP or UDP filter profile without specifying its sequence number.

Note that the sequence number can be found by running the show access-list (IPv4 Software ACLs) command.

Syntax [tcp|udp]

```
[<sequence-number>] {deny|permit} {tcp|udp}
   <source>
   {eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>}
   <destination>
   [eq <destport>|lt <destport>|gt <destport>|ne <destport>]
   [log]

no {deny|permit} {tcp|udp}
   <source>
   {eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>}
   <destination>
   [eq <destport>|lt <destport>|gt <destport>|ne <destport>]
   [log]

no <sequence-number>
```

Parameter	Description	
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.	
deny	Access-list rejects packets that match the source and destination filtering specified with this command.	
permit	Access-list permits packets that match the source and destination filtering specified with this command.	
tcp	The access-list matches only TCP packets.	
udp	The access-list matches only UDP packets.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	any	Matches any source IP address.
<sourceport>	The source port number, specified as an integer between 0 and 65535.	

Parameter(cont.)	**Description**(cont.)	
<destination>	The destination address of the packets. You can specify a single host, a subnet, or all destinations. The following are the valid formats for specifying the destination:	
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	`any`	Matches any destination IP address.
<destport>	The destination port number, specified as an integer between 0 and 65535.	
`eq`	Matches port numbers equal to the port number specified immediately after this parameter.	
`lt`	Matches port numbers less than the port number specified immediately after this parameter.	
`gt`	Matches port numbers greater than the port number specified immediately after this parameter.	
`ne`	Matches port numbers not equal to the port number specified immediately after this parameter.	
`log`	Log the results.	

Mode IPv4 Extended ACL Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number.

Note The access control list being configured is selected by running the access-list (extended numbered) command or the access-list extended (named) command, with the required access control list number, or name - but with no further parameters selected.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Example 1 [creating a list] To add a new entry to the access-list named `my-list` that will reject TCP packets from `10.0.0.1` on TCP port `10` to `192.168.1.1` on TCP port `20`, use the commands:

```
awplus# configure terminal
awplus(config)# access-list extended my-list
awplus(config-ip-ext-acl)# deny tcp 10.0.0.1/32 eq 10
                           192.168.1.1/32 eq 20
```

Example 2 [adding to a list]

To insert a new entry with sequence number `5` of the access-list named `my-list` that will accept UDP packets from `10.1.1.0/24` network to `192.168.1.0/24` network on UDP port `80`, use the commands:

```
awplus# configure terminal
awplus(config)# access-list extended my-list
awplus(config-ip-ext-acl)# 5 permit udp 10.1.1.0/24
192.168.1.0/24 eq 80
```

Related Commands

access-list extended (named)
access-list (extended numbered)
show access-group
show running-config
show ip access-list

access-list standard (named)

This command configures a standard named access-list that permits or denies packets from a specific source IP address. You can either create a standard named ACL together with an ACL filter entry in the Global Configuration mode, or you can use the IPv4 Standard ACL Configuration mode for sequenced ACL filter entry after first entering an access-list name.

The no variant of this command removes a specified standard named access-list.

Syntax [list-name]

```
access-list standard <standard-access-list-name>

no access-list standard <standard-access-list-name>
```

Parameter	Description
<standard-access-list-name>	Specify a name for the standard access-list.

Syntax [deny|permit]

```
access-list standard <standard-access-list-name> {deny|permit}
   <source>

no access-list standard <standard-access-list-name> {deny|permit}
   <source>
```

Parameter	Description	
<standard-access-list-name>	Specify a name for the standard access-list.	
deny	The access-list rejects packets that match the source filtering specified with this command.	
permit	The access-list permits packets that match the source filtering specified with this command.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any source IP address within the specified subnet.
	any	Matches any source IP address.

Mode Global Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage Use this command when configuring a standard named access-list for filtering IP software packets. For backwards compatibility you can either create the access-list from within this command, or you can enter this command followed by only the standard access-list name then enter. This latter method moves you to the IPv4 Standard ACL Configuration mode for the selected standard named access-list, and from here you can configure the deny or permit filters for this selected standard named access-list.

See the table "IPv4 Software Access List Commands and Prompts" in this chapter which shows the prompts at which ACL commands are entered. See the relevant links shown for the Related Commands.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Examples To define a standard access-list named `my-list` and deny any packets from any source, use the commands:

```
awplus# configure terminal
awplus(config)# access-list standard my-list deny any
```

Alternatively, to define a standard access-list named `my-list` and enter the IPv4 Standard ACL Configuration mode to deny any packets from any source, use the commands:

```
awplus# configure terminal
awplus(config)# access-list standard my-list
awplus(config-ip-std-acl)# 5 deny any
```

Related Commands
(access-list standard named filter)
show access-group
show running-config
show ip access-list

access-list (standard numbered)

This command configures a standard numbered access-list that permits or denies packets from a specific source IP address. You can either create a standard numbered ACL together with an ACL filter entry in the Global Configuration mode, or you can use the IPv4 Standard ACL Configuration mode for sequenced ACL filter entry after first entering an access-list number.

The no variant of this command removes a specified standard numbered access-list.

Syntax [list-number]

```
access-list {<1-99>|<1300-1999>}
no access-list {<1-99>|<1300-1999>}
```

Parameter	Description
<1-99>	IP standard access-list.
<1300-1999>	IP standard access-list (expanded range).

Syntax [deny|permit]

```
access-list {<1-99>|<1300-1999>} {deny|permit} <source>
no access-list {<1-99>|<1300-1999>} {deny|permit} <source>
```

Parameter	Description	
<1-99>	IP standard access-list.	
<1300-1999>	IP standard access-list (expanded range).	
`deny`	Access-list rejects packets from the specified source.	
`permit`	Access-list accepts packets from the specified source.	
<source>	The source address of the packets. You can specify a single host, a subnet, or all sources. The following are the valid formats for specifying the source:	
	<ip-addr> <reverse-mask>	Enter an IPv4 address followed by a reverse mask in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
	`any`	Matches any source IP address.

Mode Global Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage Use this command when configuring a standard numbered access-list for filtering IP software packets. For backwards compatibility you can either create the access-list from within this command, or you can enter this command followed by only the standard access-list name. This moves you to the IPv4 Standard ACL Configuration mode for the selected standard numbered access-list, and from here you can configure the deny or permit filters for this selected standard numbered access-list.

See the table "IPv4 Software Access List Commands and Prompts" in this chapter which shows the prompts at which ACL commands are entered. See the relevant links shown for the Related Commands.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Example To create ACL number `67` that will deny packets from subnet `172.16.10`, use the commands:

```
awplus# configure terminal
awplus(config)# access-list 67 deny 172.16.10.0 0.0.0.255
```

Alternatively, to enter the IPv4 Standard ACL Configuration mode to create the ACL filter and deny packets from subnet `172.16.10.0` for the standard numbered access-list `67`, use the commands:

```
awplus# configure terminal
awplus(config)# access-list 67
awplus(config-ip-std-acl)# deny 172.16.10.0 0.0.0.255
```

Related Commands
(access-list standard named filter)
show access-group
show running-config
show ip access-list

(access-list standard named filter)

This ACL filter adds a source IP address filter entry to a current named standard access-list. If the sequence number is specified, the new filter entry is inserted at the specified location. Otherwise, the new entry is added at the end of the access-list.

The no variant of this command removes a source IP address filter entry from the current named standard access-list. You can specify the source IP address filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its source IP address filter profile without specifying its sequence number.

Note that the sequence number can be found by running the show access-list (IPv4 Software ACLs) command.

Syntax

```
[<sequence-number>] {deny|permit} {<source> [exact-match]|any}
no {deny|permit} {<source> [exact-match]|any}
no <sequence-number>
```

Parameter	Description	
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.	
deny	Access-list rejects packets of the source filtering specified.	
permit	Access-list allows packets of the source filtering specified	
<source>	The source address of the packets. You can specify either a subnet or all sources. The following are the valid formats for specifying the source:	
	<ip-addr>/<prefix>	An IPv4 address, followed by a forward slash, then the prefix length. This matches any destination IP address within the specified subnet.
	<ip-addr>	An IPv4 address in a.b.c.d format.
exact-match	Specify an exact IP prefix to match on.	
any	Matches any source IP address.	

Mode IPv4 Standard ACL Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number.

Note

The access control list being configured is selected by running the access-list standard (named) command with the required access control list number, or name, but with no further parameters selected.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Example Use the following commands to add a new filter entry to access-list `my-list` that will reject IP address `10.1.1.1`:

```
awplus# configure terminal
awplus(config)# access-list standard my-list
awplus(config-ip-std-acl)# deny 10.1.1.1/32
```

Example Use the following commands to insert a new filter entry into access-list `my-list` at sequence position number `15` that will accept IP network `10.1.2.0`:

```
awplus# configure terminal
awplus(config)# access-list standard my-list
awplus(config-ip-std-acl)# 15 permit 10.1.2.0/24
```

Related Commands
access-list standard (named)
show access-group
show running-config
show ip access-list

(access-list standard numbered filter)

This ACL filter adds a source IP address filter entry to a current standard numbered access-list. If a sequence number is specified, the new filter entry is inserted at the specified location. Otherwise, the new filter entry is added at the end of the access-list.

The no variant of this command removes a source IP address filter entry from the current standard numbered access-list. You can specify the source IP address filter entry for removal by entering either its sequence number (e.g. `no 10`), or by entering its source IP address filter profile without specifying its sequence number.

Note that the sequence number can be found by running the show access-list (IPv4 Software ACLs) command.

Syntax

```
[<sequence-number>] {deny|permit} {<source>|host <host-address>|any}
no {deny|permit} {<source>|host <host-address>|any}
no <sequence-number>
```

Parameter	Description	
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.	
deny	Access-list rejects packets of the type specified.	
permit	Access-list allows packets of the type specified	
<source>	The source address of the packets. You can specify either a subnet or all sources. The following are the valid formats for specifying the source:	
	<ip-addr> <reverse-mask>	Enter a reverse mask for the source address in dotted decimal format. For example, entering `192.168.1.1 0.0.0.255` is the same as entering `192.168.1.1/24`.
	<ip-addr>	An IPv4 address in a.b.c.d format.
host	A single source host.	
<host-address>	Single source host address.	
any	Matches any source IP address.	

Mode IPv4 Standard ACL Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage An ACL can be configured with multiple ACL filters using sequence numbers. If the sequence number is omitted, the next available multiple of 10 will be used as the sequence number for the new filter. A new ACL filter can be inserted into the middle of an existing list by specifying the appropriate sequence number.

Note The access control list being configured is selected by running the access-list standard (named) command with the required access control list number, or name, but with no further parameters selected.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Example To add a new entry accepting the IP network `10.1.1.0/24` at the sequence number `15` position, use the commands:

```
awplus# configure terminal
awplus(config)# access-list 99
awplus(config-ip-std-acl)# 15 permit 10.1.2.0 0.0.0.255
```

Related Commands
access-list (standard numbered)
show access-group
show running-config
show ip access-list

clear ip prefix-list

Use this command to reset the hit count to zero in the prefix-list entries.

Syntax `clear ip prefix-list [<list-name>] [<ip-address>/<mask>]`

Parameter	Description
<list-name>	The name of the prefix-list.
<ip-address>/<mask>	The IP prefix and length.

Mode Privileged Exec

Example To clear a prefix-list named List1:

```
awplus# clear ip prefix-list List1
```

ip prefix-list

Use this command to create an entry for a prefix list.

Use the no variant of this command to delete the prefix-list entry.

Syntax

```
ip prefix-list <list-name> seq <1-429496725>
   {deny|permit}
   {any|<ip-prefix>}
   [ge <0-32>] [le <0-32>]

ip prefix-list <list-name> description <text>

ip prefix-list sequence-number

no ip prefix-list <list-name> seq <1-429496725>

no ip prefix-list <list-name> description <text>

no ip prefix-list sequence-number
```

Parameter	Description
`<list-name>`	Specifies the name of a prefix list.
`seq <1-429496725>`	Sequence number of the prefix list entry.
`deny`	Specifies that the prefixes are excluded from the list.
`permit`	Specifies that the prefixes are included in the list.
`<ip-prefix>`	A.B.C.D/M specifies the IP address and length of the network mask.
`any`	Any prefix match. Same as 0.0.0.0/0 le 32.
`le <0-32>`	Specifies the maximum prefix length to be matched.
`ge <0-32>`	Specifies the minimum prefix length to be matched.
`description <text>`	Text description of the prefix list.
`sequence-number`	Specify sequence numbers included or excluded in prefix list.

Mode Global Configuration

Usage When the device processes a prefix list, it starts to match prefixes from the top of the prefix list, and stops whenever a match or deny occurs. To promote efficiency, use the seq parameter and place common matches or denials towards the top of the list. If you do not use the seq parameter, the sequence values are generated in the sequence of 5.

The parameters ge and le specify the range of the prefix lengths to be matched. When setting these parameters, set the le value to be less than 32, and the ge value to be less than the le value.

Example In the below sample configuration, the last `ip prefix-list` command in the below list matches all, and the first `ip prefix-list` command denies the IP network `76.2.2.0`:

```
awplus(config)# router bgp 100
awplus(config-router)# network 172.1.1.0
awplus(config-router)# network 172.1.2.0
awplus(config-router)# neighbor 10.6.5.3 remote-as 300
awplus(config-router)# neighbor 10.6.5.3 prefix-list mylist out
awplus(config-router)# exit
awplus(config)# ip prefix-list mylist seq 5 deny
                76.2.2.0/24
awplus(config)# ip prefix-list mylist seq 100 permit any
```

To deny the IP addresses between `10.0.0.0/14` (`10.0.0.0 255.252.0.0`) and `10.0.0.0/22` (`10.0.0.0 255.255.252.0`) within the `10.0.0.0/8` (`10.0.0.0 255.0.0.0`) addressing range, enter the following commands:.

```
awplus# configure terminal
awplus(config)# ip prefix-list mylist seq 12345 deny 10.0.0.0/
                8 le 22 ge 14
```

Related Commands

match ip address
neighbor prefix-list
match route-type
show access-group

maximum-access-list

Sets the maximum number of filters that can be added to any access-list. These are access-lists within the ranges <1-199>, <1300-1999> and <2000-2699> and named standard and extended access-lists.

The no variant of this command removes the limit on the number of filters that can be added to a software access-list

Syntax

```
maximum-access-list <1-4294967294>
no maximum-access-list
```

Parameter	Description
<1-4294967294>	Filter range.

Mode Global Configuration

Example To set the maximum number of software filters to `200`:

```
awplus# configure terminal
awplus(config)# maximum-access-list 200
```

Related Commands remote-command

show access-list (IPv4 Software ACLs)

Use this command to display the specified access-list, or all access-lists if none have been specified. Note that only defined access-lists are displayed. An error message is displayed for an undefined access-list

Syntax

```
show access-list
    [<1-99>|<100-199>|<1300-1999>|<2000-2699>|<3000-3699>|
    <4000-4499>|<access-list-name>]
```

Parameter	Description
<1-99>	IP standard access-list.
<100-199>	IP extended access-list.
<1300-1999>	IP standard access-list (standard - expanded range).
<2000-2699>	IP extended access-list (extended - expanded range).
<3000-3699>	Hardware IP access-list.
<4000-4499>	Hardware MAC access-list.
<access-list-name>	IP named access-list.

Mode User Exec and Privileged Exec

Example To show all access-lists configured on the switch:

```
awplus# show access-list
```

```
Standard IP access list 1
    deny 172.16.2.0, wildcard bits 0.0.0.255
Standard IP access list 20
    deny 192.168.10.0, wildcard bits 0.0.0.255
    deny 192.168.12.0, wildcard bits 0.0.0.255
Hardware IP access list 3001
    permit ip 192.168.20.0 255.255.255.0 any
Hardware IP access list 3020
    permit tcp any 192.0.2.0/24
awplus#show access-list 20
```

Example To show the access-list with an ID of 20:

```
awplus# show access-list 20
```

```
Standard IP access-list 20
    deny 192.168.10.0, wildcard bits 0.0.0.255
    deny 192.168.12.0, wildcard bits 0.0.0.255
```

Note the below error message if you attempt to show an undefined access-list:

```
awplus# show access-list 2
```

```
% Can't find access-list 2
```

Related Commands

access-list standard (named)
access-list (standard numbered)
access-list (extended numbered)

show ip access-list

Use this command to display IP access-lists.

Syntax

```
show ip access-list [<1-99>|<100-199>|<1300-1999>|<2000-2699>|
   <access-list-name>]
```

Parameter	Description
<1-99>	IP standard access-list.
<100-199>	IP extended access-list.
<1300-1999>	IP standard access-list (expanded range).
<2000-2699>	IP extended access-list (expanded range).
<access-list-name>	IP named access-list.

Mode User Exec and Privileged Exec

Example

```
awplus# show ip access-list
```

Output Figure 57-1: Example output from the **show ip access-list** command

```
Standard IP access-list 1
    permit 172.168.6.0, wildcard bits 0.0.0.255
    permit 192.168.6.0, wildcard bits 0.0.0.255
```

show ip prefix-list

Use this command to display the prefix-list entries. Note that this command is valid for RIP and BGP routing protocols only.

Syntax `show ip prefix-list [<name>|detail|summary]`

Parameter	Description
<name>	Name of a prefix list.
`detail`	Detail of the prefix list.
`summary`	Summary of prefix lists.

Mode User Exec and Privileged Exec

Example

```
awplus# show ip prefix-list
awplus# show ip prefix-list 10.10.0.98/8
awplus# show ip prefix-list detail
```

Chapter 58: IPv6 Hardware Access Control List (ACL) Commands

Introduction 58.2
IPv6 Hardware Access List Commands and Prompts 58.3
Command List 58.4
commit (IPv6) 58.4
ipv6 access-list (named) 58.5
(ipv6 access-list named ICMP filter) 58.7
(ipv6 access-list named protocol filter) 58.10
(ipv6 access-list named TCP UDP filter) 58.14
ipv6 traffic-filter 58.18
show ipv6 access-list (IPv6 Hardware ACLs) 58.20

Introduction

This chapter provides an alphabetical reference for the IPv6 Hardware Access Control List (ACL) commands, and contains detailed command information and command examples about IPv6 hardware ACLs, which are applied directly to interfaces using the ipv6 traffic-filter command.

Note

See Chapter 55, Access Control Lists Introduction for descriptions of ACLs, and for further information about rules when applying ACLs see the ACL Rules section.

See ACL Filter Sequence Numbers and ACL Filter Sequence Number Behavior sections in Chapter 55, Access Control Lists Introduction about ACL Filters.

To apply ACLs to an LACP channel group, apply it to all the individual switch ports in the channel group. To apply ACLs to a static channel group, apply it to the static channel group itself. For more information on link aggregation see Chapter 20, Link Aggregation Introduction and Configuration, and Chapter 21, Link Aggregation Commands.

Note that text in parenthesis in command names indicates usage not keyword entry. For example, ipv6-access-list (named) indicates named IPv6 ACLs entered as `ipv6-access-list <name>` where `<name>` is a placeholder not a keyword.

Note also that parenthesis surrounding ACL filters indicates the type of ACL filter not the keyword entry in the CLI, such as (ipv6 access-list standard IPv6 filter) represents command entry in the format shown in the syntax `[<sequence-number>] {deny|permit} {<IPv6-source-address/prefix-length>|any}`.

Note

Hardware ACLs will permit access unless explicitly denied by an ACL action.

IPv6 Hardware Access List Commands and Prompts

Many of the ACL commands operate from sub-modes that are specific to particular ACL types. The table "IPv6 Hardware Access List Commands and Prompts" shows the CLI prompts at which ACL commands are entered.

Table 58-1: IPv6 Hardware Access List Commands and Prompts

Command Name	Command Mode	Prompt
show ipv6 access-list (IPv6 Hardware ACLs)	Privileged Exec	awplus#
ipv6 access-list (named)	Global Configuration	awplus(config)#
(ipv6 access-list named ICMP filter)	Global Configuration	awplus(config)#
ipv6 traffic-filter	Interface Configuration	awplus(config-if)#
commit (IPv6)	IPv6 Hardware ACL Configuration	awplus(config-ipv6-hw-acl)#
(ipv6 access-list named ICMP filter)	IPv6 Hardware ACL Configuration	awplus(config-ipv6-hw-acl)#
(ipv6 access-list named protocol filter)	IPv6 Hardware ACL Configuration	awplus(config-ipv6-hw-acl)#
(ipv6 access-list named TCP UDP filter)	IPv6 Hardware ACL Configuration	awplus(config-ipv6-hw-acl)#

Command List

commit (IPv6)

Use this command to commit the ACL filter configuration to hardware immediately without exiting Hardware ACL Configuration mode.

Syntax `commit`

Mode IPv6 Hardware ACL Configuration

Usage Normally, when a hardware ACL is edited, the new configuration state of the ACL is not written to hardware until you exit Hardware ACL Configuration mode. By entering this command you can ensure that the current state of a hardware access-list that is being edited is written to hardware immediately.

Scripts typically do not include the exit command to exit configuration modes, potentially leading to ACL filters in hardware not being correctly updated. Using this commit command in a configuration script after specifying a hardware ACL filter ensures that it is updated in the hardware.

Examples To update the hardware with the ACL filter configuration, use the command:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-ipv6-acl
awplus(config-ipv6-hw-acl)# commit
```

Related Commands ipv6 access-list (named)

ipv6 access-list (named)

Use this command to either create a new IPv6 hardware access-list, or to select an existing IPv6 hardware access-list in order to apply a filter entry to it.

Use the no variant of this command to delete an existing IPv6 hardware access-list.

Note Before you can delete an access-list, you must first remove it from any interface it is assigned to.

Syntax

```
ipv6 access-list <ipv6-access-list-name>
no ipv6 access-list <ipv6-access-list-name>
```

Parameter	Description
<ipv6-access-list-name>	Specify an IPv6 access-list name.

Mode Global Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicitly match a filter is permitted.

Usage Use IPv6 hardware named access-lists to control the transmission of IPv6 packets on an interface, and restrict the content of routing updates. The switch stops checking the IPv6 hardware named access-list when a match is encountered.

For backwards compatibility you can either create IPv6 hardware named access-lists from within this command, or you can enter `ipv6 access-list` followed by only the IPv6 hardware named access-list name. This latter (and preferred) method moves you to the `(config-ipv6-hw-acl)` prompt for the selected IPv6 hardware named access-list number, and from here you can configure the filters for this selected IPv6 hardware named access-list.

Note Hardware ACLs will permit access unless explicitly denied by an ACL action.

Examples To create an IPv6 access-list named `my-ipv6-acl`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-ipv6-acl
awplus(config-ipv6-hw-acl)#
```

To delete the IPv6 access-list named `my-ipv6-acl`, use the commands:

```
awplus# configure terminal
awplus(config)# no ipv6 access-list my-ipv6-acl
```

Validation Commands show ipv6 access-list (IPv6 Hardware ACLs)

Related Commands (ipv6 access-list named ICMP filter)
(ipv6 access-list named protocol filter)
(ipv6 access-list named TCP UDP filter)
ipv6 traffic-filter
show ipv6 access-list (IPv6 Hardware ACLs)

(ipv6 access-list named ICMP filter)

Use this ACL filter to add a filter entry for an IPv6 source and destination address and prefix, with ICMP (Internet Control Message Protocol) packets, to the current named IPv6 access-list. If a sequence number is specified, the new entry is inserted at the specified location. Otherwise, the new entry is added at the end of the access-list.

Note that specifying the send-to-cpu parameter could result in EPSR healthcheck messages and other control packets being dropped.

As an optional parameter vlan can be matched for tagged (802.1q) packet.

The no variant of this command removes a filter entry for an IPv6 source and destination address and prefix, with ICMP (Internet Control Message Protocol) packets, from the current named IPv6 access-list. You can specify the filter entry for removal by entering either its sequence number, or its filter entry profile.

Note Hardware ACLs will permit access unless explicitly denied by an ACL action.

Syntax [ip|icmp]

```
[<sequence-number>
   {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   {ipv6|icmp}
   {<ipv6-source-address/prefix-length>|
   <ipv6-source-address> <ipv6-source-wildcard>|
   host <ipv6-source-host>|any}
   {<ipv6-destination-address/prefix-length>|
   <ipv6-destintation-addr> <ipv6-destination-wildcard>|
   host <ipv6-destination-host-address>|any} [<icmp-type>]
   [vlan <1-4094>]

no [<sequence-number>]
   {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   {ip|icmp}
   {<ipv6-source-address/prefix-length>|
   <ipv6-source-address> <ipv6-source-wildcard>|
   host <ipv6-source-host>|any}
   {<ipv6-destination-address/prefix-length>|
   <ipv6-destination-address> <ipv6-destination-wildcard>|
   host <ipv6-destination-host-address>|any} [<icmp-type>]
   [vlan <1-4094>]

no [<sequence-number>]
```

Parameter	Description
<*sequence-number*>	<1-65535> *The sequence number for the filter entry of the selected access control list.*
deny	Specifies the packets to reject.
permit	Specifies the packets to permit.
send-to-cpu	Specifies the packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.

Parameter(cont.)	Description(cont.)
copy-to-cpu	Specifies the packets to copy to the CPU.
copy-to-mirror	Specifies the packets to copy to the mirror port.
ipv6	IPv6 packet, defined by the following parameters.
icmp	ICMP packet, defined by the following parameters.
<ipv6-source-address/ prefix-length>	Specifies a source address and prefix length. The IPv6 address prefix uses the format X:X::/ prefix-length. The prefix-length is usually set between 0 and 64, or has the value 128.
<ipv6-source-address>	Specifies the IPv6 source address. The IPv6 address uses the format X:X::X:X.
<ipv6-source-wildcard>	Specifies source wildcard bits in IPv6 format X:X::X:X. Note that binary 1 represents a don't care condition, and binary 0 represents a match.
host *<ipv6-source-host>*	Specifies a single source host address. The IPv6 address uses the format X:X::X:X.
any	Specifies any Source host.
<ipv6-destination-address/prefix-length>	Specifies a destination address and prefix length. The IPv6 address uses the format X:X::X:X/Prefix-Length. The prefix-length is usually set between 0 and 64, or has the value 128.
<ipv6-destination-addrress>	Specifies a destination address. The IPv6 address uses the format X:X::X:X.
<ipv6-destination-wildcard>	Specify destination Wildcard bits in IPv6 format X:X::X:X.
host *<ipv6-destination-host-address>*	Specify a single destination host address. The IPv6 address uses the format X:X::X:X.
any	Specifies any destination host.
<icmp-type>	Optional. Specify to filter by ICMP message type number. Valid values are from 0 to 255.
vlan	This parameter can be used in either single or double-tagged VLAN networks. It is the conventional VLAN tag (VID). In a double-tagged network it is sometimes referred to as the STAG.
<1-4094>	The VLAN VID.

Mode IPv6 Hardware ACL Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicate match a filter is permitted.

Examples

To specify a hardware IPv6 access-list named `my-acl1` and add an ACL filter entry that blocks all ICMP6 echo requests, enter the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-acl1
awplus(config-ipv6-hw-acl)# deny icmp any any icmp-type 128
```

To specify a hardware IPv6 access-list named `my-acl2` and add an ACL filter entry that blocks all ICMP6 echo requests on the default VLAN (`vlan1`), enter the following commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-acl2
awplus(config-ipv6-hw-acl)# deny icmp any any icmp-type 128
vlan 1
```

To remove an ACL filter entry that blocks all ICMP6 echo requests from he hardware IPv6 access-list named `my-acl1`, enter the following commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-acl1
awplus(config-ipv6-hw-acl)# no deny icmp any any icmp-type 128
```

Validation Commands

show ipv6 access-list (IPv6 Hardware ACLs)

Related Commands

ipv6 access-list (named)
(ipv6 access-list named protocol filter)
(ipv6 access-list named TCP UDP filter)
ipv6 traffic-filter
show ipv6 access-list (IPv6 Hardware ACLs)

(ipv6 access-list named protocol filter)

Use this ACL filter to add a filter entry for an IPv6 source and destination address and prefix, with an IP protocol type specified, to the current named IPv6 access-list. If a sequence number is specified, the new entry is inserted at the specified location. Otherwise, the new entry is added at the end of the access-list.

Note that specifying the send-to-cpu parameter could result in EPSR healthcheck messages and other control packets being dropped.

The no variant of this command removes a filter entry for an IPv6 source and destination address and prefix, with an IP protocol type specified, from the current named IPv6 access-list. You can specify the filter entry for removal by entering either its sequence number, or its filter entry profile.

Syntax

```
[<sequence-number>
   {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   {ipv6|proto <ip-protocol>}
   {<ipv6-source-prefix/prefix-length>|<ipv6-source-address>
   <ipv6-source-wildcard>|host <ipv6-source-host>|any}
   {<ipv6-destination-prefix/prefix-length>|
   <ipv6-destination-address> <ipv6-destination-wildcard>|
   host <ipv6-destination-host>|any}

[<sequence-number>]
   no {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror}
   {ipv6|proto <ip-protocol>}
   {<ipv6-source-prefix/prefix-length>|<ipv6-source-address>
   <ipv6-source-wildcard>|host <ipv6-source-host>|any}
   {<ipv6-destination-prefix/prefix-length>|
   <ipv6-destination-address> <ipv6-destination-wildcard>|
   host <ipv6-destination-host>|any}

no [<sequence-number>]
```

Parameter	Description
<sequence-number>	<1-65535> *The sequence number for the filter entry of the selected access control list.*
deny	Specifies packets to reject.
permit	Specifies packets to permit.
send-to-cpu	Specifies packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.
copy-to-cpu	Specifies packets to copy to the CPU.
copy-to-mirror	Specifies packets to copy to the mirror port.
ipv6	Specifies IPv6 packet.
proto *<ip-protocol>*	Specify IP protocol number <1-255>.

Parameter(cont.)	Description(cont.)
<ip-protocol>	The IP protocol number, as defined by IANA (Internet Assigned Numbers Authority http://www.iana.org/assignments/protocol-numbers)
	Protocol Number
	1
	2
	3
	4

	254
	255
<ipv6-source-prefix/ prefix-length>	Specify source address and mask. The IPv6 address uses the format X:X::X:X/Prefix-Length. The prefix-length is usually set between 0 and 64, or has the value 128.
<ipv6-source-address>	Specifies the source address. The IPv6 address uses the format X:X::X:X.
<ipv6-source-wildcard>	Specifies the source wildcard bits, in IPv6 format X:X::X:X.
host *<ipv6-source-host>*	Specifies a single source host. The IPv6 address uses the format X:X::X:X.
any	Specifies any source host. An abbreviation for the IPv6 prefix *::/0*
<ipv6-dest-prefix/prefix-length>	Specifies a destination address and mask. The IPv6 address prefix uses the format X:X::/ prefix-length. The prefix-length is usually set between 0 and 64, or has the value 128.
<ipv6-destination-address>	Specify destination address. The IPv6 address uses the format X:X::X:X.
<ipv6-destination-wildcard>	Specify destination wildcard bits in IPv6 format X:X::X:X
host *<ipv6-destination-host>*	Specify a single destination host address. The IPv6 address uses the format X:X::X:X.
any	Specifies any destination host. An abbreviation for the IPv6 prefix *::/0*

Parameter(cont.)	Description(cont.)
`vlan`	This parameter can be used in either single or double-tagged VLAN networks. It is the conventional VLAN tag (VID). In a double-tagged network it is sometimes referred to as the STAG.
<1-4094>	The VLAN VID.

Mode IPv6 Hardware ACL Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicate match a filter is permitted.

Usage This command adds a hardware classification filter (for use with features such as QoS), to a current standard IPv6 access-list. The filter will match on any IP protocol type packet that has the specified source and destination IPv6 addresses and the specified IP protocol type. The parameter `any` may be specified if an address does not matter,

Note Hardware ACLs will permit access unless explicitly denied by an ACL action.

Examples To add an ACL filter entry to block IP traffic from network `2001:0db8::0/64` to the hardware IPv6 access-list named `my-acl`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-acl
awplus(config-ipv6-hw-acl)# deny ipv6 2001:0db8::0/64
```

To remove an ACL filter entry that blocks all IPv6 traffic from network `2001:0db8::0/64` from the hardware IPv6 access-list named `my-acl`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-acl
awplus(config-ipv6-hw-acl)# no deny ipv6 2001:0db8::0/64
```

Validation Commands show ipv6 access-list (IPv6 Hardware ACLs)

Related Commands ipv6 access-list (named)
(ipv6 access-list named ICMP filter)
(ipv6 access-list named TCP UDP filter)
ipv6 traffic-filter
show ipv6 access-list (IPv6 Hardware ACLs)

(ipv6 access-list named TCP UDP filter)

Use this ACL filter to add a filter entry for an IPv6 source and destination address and prefix, with TCP (Transmission Control Protocol) or UDP (User Datagram Protocol) source and destination ports specified, to the current named IPv6 access-list. If a sequence number is specified, the new entry is inserted at the specified location. Otherwise, the new entry is added at the end of the access-list.

Note that specifying the send-to-cpu parameter could result in EPSR healthcheck messages and other control packets being dropped.

The no variant of this command removes a filter entry for an IPv6 source and destination address and prefix, with TCP or UDP source and destination ports specified, from the current named IPv6 access-list. You can specify the filter entry for removal by entering either its sequence number, or its filter entry profile.

Syntax

```
[<sequence-number>]
   {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror} {tcp|udp}
   {<ipv6-source-prefix/prefix-length>|
   <ipv6-source-address> <ipv6-source-wildcard>|
   host <ipv6-source-host>|any}
   {eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>}|
   [range <start-range> <end-range>]
   {<ipv6-destination-prefix/prefix-length>|
   <ipv6-destination-address> <ipv6-destination-wildcard>|
   host <ipv6-destination-host>|any}
   {[eq <destport>|lt <destport>|gt <destport>|ne <destport>}
   [range <start-range> <end-range>]

no {deny|permit|send-to-cpu|copy-to-cpu|copy-to-mirror} {tcp|udp}
   {<ipv6-source-prefix/prefix-length>|
   <ipv6-source-address> <ipv6-source-wildcard>|
   host <ipv6-source-host>|any}
   {eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>}|
   [range <start-range> <end-range>]
   {<ipv6-destination-prefix/prefix-length>|
   <ipv6-destination-address> <ipv6-destination-wildcard>
   |host <ipv6-destination-host>|any}
   {eq <destport>|lt <destport>|gt <destport>|ne <destport>}|
   [range <start-range> <end-range>]

no <sequence-number>
```

Parameter	Description
<sequence-number>	<1-65535> *The sequence number for the filter entry of the selected access control list.*
deny	Specify packets to reject.
permit	Specifies the packets to permit.
send-to-cpu	Specifies the packets to send to the CPU. Specifying this parameter could result in EPSR healthcheck messages and other control packets being dropped.
copy-to-cpu	Specifies the packets to copy to the CPU.
copy-to-mirror	Specifies the packets to copy to the mirror port.
tcp	Specifies a TCP packet.

Parameter(cont.)	Description(cont.)
udp	Specifies a UDP packet.
<ipv6-source-prefix/ prefix-length>	Specifies the source address with mask. The IPv6 address prefix uses the format X:X::/prefix-length. The prefix-length is usually set between 0 and 64, or has the value 128.
<ipv6-source-address>	Specifies the source address. The IPv6 address uses the format X:X::X:X.
<ipv6-source-wildcard>	Specifies the Source Wildcard bits in IPv6 format X:X::X:X.
host *<ipv6-source-host>*	Specifies the a single source host. The IPv6 address uses the format X:X::X:X.
any	Specifies any Source host. An abbreviation for the IPv6 prefix *::/0*.
eq	Equal to.
lt	Less than.
gt	Greater than.
ne	Not equal to.
<sourceport>	The source port number, specified as an integer between 0 and 65535.
<destport>	The destination port number, specified as an integer between 0 and 65535.
range	Range of port numbers. Match only packets within range.
<start-range>	The port number at the start of the range *<0-65535>*.
<end-range>	The port number at the end of the range *<0-65535>*.
<ipv6-dest-prefix/ prefix-length>	Specify destination address with mask. The IPv6 address prefix uses the format X:X::/prefix-length. The prefix-length is usually set between 0 and 64, or has the value 128.
<ipv6-destination-address>	Specify destination address. The IPv6 address uses the format X:X::X:X.
<ipv6-destination-wildcard>	Specify destination wildcard bits in IPv6 format X:X::X:X .
host *<ipv6-destination-host>*	Specify a single destination host address. The IPv6 address uses the format X:X::X:X.
any	Specifies any destination host. An abbreviation for the IPv6 prefix ::/0.

Parameter(cont.)	Description(cont.)
`vlan`	This parameter can be used in either single or double-tagged VLAN networks. It is the conventional VLAN tag (VID). In a double-tagged network it is sometimes referred to as the STAG.
<1-4094>	The VLAN VID.

Mode IPv6 Hardware ACL Configuration

Default Any traffic on an interface controlled by a hardware ACL that does not explicate match a filter is permitted.

Usage The filter entry will match on any TCP or UDP packet that has the specified source and destination IPv6 addresses and TCP or UDP type. The parameter `any` may be specified if an address does not matter.

Note Hardware ACLs will permit access unless explicitly denied by an ACL action.

Example To add an ACL filter entry that blocks all SSH traffic from network `2001:0db8::0/64` to the hardware IPv6 access-list named `my-acl`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-acl
awplus(config-ipv6-hw-acl)# deny tcp 2001:0db8::0/64 any eq 22
```

To add an ACL filter entry that blocks all SSH traffic from network `2001:0db8::0/64` on the default VLAN (`vlan1`) to the hardware IPv6 access-list named `my-acl`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-acl
awplus(config-ipv6-hw-acl)# deny tcp 2001:0db8::0/64 any eq 22
vlan 1
```

To remove an ACL filter entry that blocks all SSH traffic from network `2001:0db8::0/64` from the hardware IPv6 access-list named `my-acl`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list my-acl
awplus(config-ipv6-hw-acl)# no deny tcp 2001:0db8::0/64 any eq
22
```

Validation Commands show ipv6 access-list (IPv6 Hardware ACLs)

Related Commands

ipv6 access-list (named)
(ipv6 access-list named ICMP filter)
(ipv6 access-list named protocol filter)
ipv6 traffic-filter
show ipv6 access-list (IPv6 Hardware ACLs)

ipv6 traffic-filter

This command adds an IPv6 hardware-based access-list to an interface. The number of access-lists that can be added is determined by the amount of available space in the hardware-based packet classification tables. You can apply an IPv6 hardware access-list to all ports or selected ports.

Use the no variant of this command to remove an IPv6 hardware-based access-list from an interface. You can remove an IPv6 hardware access-list from all ports or selected ports as required.

Syntax

```
ipv6 traffic-filter <ipv6-access-list-name>
no ipv6 traffic-filter <ipv6-access-list-name>
```

Parameter	Description
<ipv6-access-list-name>	Hardware IPv6 access-list name.

Mode Interface Configuration (to apply an IPv6 hardware ACL to a specific switch port) and Global Configuration (to apply an IPv6 hardware ACL to all of the switch ports)

Usage This command adds an IPv6 hardware-based access-list to an interface. The number of access-lists that can be added is determined by the amount of available space in the hardware-based packet classification tables.

To apply the access-list to all ports on the switch, execute the command in the Global Configuration mode. To apply the access-list to a Layer 2 interface or Layer 2 interface range, apply the command in the Interface Configuration mode. See the examples for each mode below.

Examples To add access-list `acl1` as a traffic-filter to all ports on the switch, enter the commands:

```
awplus# configure terminal
awplus(config)# ipv6 traffic-filter acl1
```

To add access-list `acl1` as a traffic-filter to interface `port1.0.1`, enter the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# ipv6 traffic-filter acl1
```

To remove access-list `acl1` as a traffic-filter from all ports on the switch, enter the commands:

```
awplus# configure terminal
awplus(config)# no ipv6 traffic-filter acl1
```

To remove access-list `acl1` as a traffic-filter from interface `port1.0.1`, enter the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# no ipv6 traffic-filter acl1
```

Related Commands

ipv6 access-list (named)
(ipv6 access-list named ICMP filter)
(ipv6 access-list named protocol filter)
(ipv6 access-list named TCP UDP filter)
ipv6 traffic-filter
show ipv6 access-list (IPv6 Hardware ACLs)

show ipv6 access-list (IPv6 Hardware ACLs)

Use this command to display all configured hardware IPv6 access-lists or the IPv6 access-list specified by name. Omitting the optional access-list name parameter will display all IPv6 ACLs.

Use the show ipv6 access-list standard command to display the IPv6 access-list specified by name as defined from the ipv6 access-list (named) command.

Syntax

```
show ipv6 access-list [<access-list-name>]
show ipv6 access-list standard [<access-list-name>]
```

Parameter	Description
standard	Named standard access-list.
<access-list-name>	Hardware IPv6 access-list name.

Mode User Exec and Privileged Exec

Example To show the standard named ipv6 access-list acl_name use the following command:

```
awplus# show ipv6 access-list standard acl_name
```

Output Figure 58-1: Example output from the **show ipv6 access-list standard** command

```
Named Standard IPv6 access-list acl_name
  deny any
```

Example To show all configured ipv6 access-lists use the command:

```
awplus# show ipv6 access-list
```

Output Figure 58-2: Example output from the **show ipv6 access-list** command

```
IPv6 access-list deny_icmp
  deny icmp any any vlan 1

IPv6 access-list deny_ssh
  deny tcp abcd::0/64 any eq 22
```

Introduction

This chapter provides an alphabetical reference for the IPv6 Software Access Control List (ACL) commands, and contains detailed command information and command examples about IPv6 software ACLs as applied to Routing and Multicasting, which are not applied to interfaces.

Note

See Chapter 55, Access Control Lists Introduction for descriptions of ACLs, and for further information about rules when applying ACLs see the ACL Rules section.

See ACL Filter Sequence Numbers and ACL Filter Sequence Number Behavior sections in Chapter 55, Access Control Lists Introduction about ACL Filters.

See all relevant Routing commands and configurations in "Layer Three, Switching and Routing" and all relevant Multicast commands and configurations in "Multicast Applications".

To apply ACLs to an LACP channel group, apply it to all the individual switch ports in the channel group. To apply ACLs to a static channel group, apply it to the static channel group itself. For more information on link aggregation see Chapter 20, Link Aggregation Introduction and Configuration, and Chapter 21, Link Aggregation Commands.

Note that text in parenthesis in command names indicates usage not keyword entry. For example, ipv6-access-list (named) indicates named IPv6 ACLs entered as `ipv6-access-list <name>` where `<name>` is a placeholder not a keyword.

Note also that parenthesis surrounding ACL filters indicates the type of ACL filter not the keyword entry in the CLI, such as (ipv6 access-list standard IPv6 filter) represents command entry in the format shown in the syntax `[<sequence-number>] {deny|permit} {<IPv6-source-address/prefix-length>|any}`.

Note

Software ACLs will deny access unless explicitly permitted by an ACL action.

IPv6 Software Access List Commands and Prompts

Many of the ACL commands operate from sub-modes that are specific to particular ACL types. The table "IPv6 Software Access List Commands and Prompts" shows the CLI prompts at which ACL commands are entered.

Table 59-1: IPv6 Software Access List Commands and Prompts

Command Name	Command Mode	Prompt
show ipv6 access-list (IPv6 Software ACLs)	Privileged Exec	`awplus#`
ipv6 access-list extended (named)	Global Configuration	`awplus(config)#`
ipv6 access-list standard (named)	Global Configuration	`awplus(config)#`
(ipv6 access-list extended IP protocol filter)	IPv6 Extended ACL Configuration	`awplus(config-ipv6-ext-acl)#`
(ipv6 access-list extended TCP UDP filter)	IPv6 Extended ACL Configuration	`awplus(config-ipv6-ext-acl)#`
(ipv6 access-list standard filter)	IPv6 Standard ACL Configuration	`awplus(config-ipv6-std-acl)#`

Command List

ipv6 access-list extended (named)

Use this command when configuring an IPv6 extended access-list for filtering frames that permit or deny IP, ICMP, TCP, UDP packets or ICMP packets with a specific value based on the source or destination.

The no variant of this command removes a specified IPv6 extended access-list.

Syntax [list-name]

```
ipv6 access-list extended <list-name>

no ipv6 access-list extended <list-name>
```

Parameter	Description
<list-name>	A user-defined name for the IPv6 software extended access-list.

Syntax [any|icmp|ip]

```
ipv6 access-list extended <list-name>
   {deny|permit} {any|icmp|ip}
   {<ipv6-source-address/prefix-length>|any}
   {<ipv6-destination-address/prefix-length>|any}
   [<icmp-type <icmp-type>][log]

no ipv6 access-list extended <list-name>
   {deny|permit} {any|icmp|ip}
   {<ipv6-source-address/prefix-length>|any}
   {<ipv6-destination-address/prefix-length>|any}
   [<icmp-type <icmp-type>][log]
```

Syntax [tcp|udp]

```
ipv6 access-list extended <list-name>
   {deny|permit} {tcp|udp}
   {<ipv6-source-address/prefix-length>|any}
   {eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>}
   {<ipv6-destination-address/prefix-length>|any}
   {eq <destport>|lt <destport>|gt <destport>|ne <destport>}
   [log]

no ipv6 access-list extended <list-name> {deny|permit} {tcp|udp}
   {<ipv6-source-address/prefix-length>|any}
   {eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>}
   {<ipv6-destination-addr/prefix-length>|any}
   {eq <destport>|lt <destport>|gt <destport>|ne <destport>}
   [log]
```

Parameter	Description
<list-name>	A user-defined name for the IPv6 software extended access-list.
deny	The IPv6 software extended access-list rejects packets that match the type, source, and destination filtering specified with this command.
permit	The IPv6 software extended access-list permits packets that match the type, source, and destination filtering specified with this command.

Parameter(cont.)	**Description**(cont.)
`any`	For ICMP|IP The IPv6 software extended access-list matches any type of packet.
`ip`	For ICMP|IP The IPv6 software extended access-list matches only IP packets.
`icmp`	For ICMP|IP The IPv6 software extended access-list matches only ICMP packets.
`tcp`	For TCP/UDP The IPv6 software extended access-list matches only TCP packets.
`udp`	For TCP/UDP The IPv6 software extended access-list matches only UDP packets.
<ipv6-source-address/prefix-length>	Specifies a source address and prefix length. The IPv6 address prefix uses the format X:X::/prefix-length. The prefix-length is usually set between 0 and 64, or has the value 128.
<ipv6-destination-address/prefix-length>	Specifies a destination address and prefix length. The IPv6 address uses the format X:X::X:X/Prefix-Length. The prefix-length is usually set between 0 and 64, or has the value 128.
`any`	Matches any IPv6 address.
<sourceport>	For TCP/UDP The source port number, specified as an integer between 0 and 65535.
<destport>	For TCP/UDP The destination port number, specified as an integer between 0 and 65535.
`icmp-type`	For ICMP|IP Matches only a specified type of ICMP messages. This is valid only when the filtering is set to match ICMP packets.
`eq`	For TCP/UDP Matches port numbers equal to the port number specified immediately after this parameter.
`lt`	For TCP/UDP Matches port numbers less than the port number specified immediately after this parameter.
`gt`	For TCP/UDP Matches port numbers greater than the port number specified immediately after this parameter.
`ne`	For TCP/UDP Matches port numbers not equal to the port number specified immediately after this parameter.

Parameter(cont.)	**Description**(cont.)	
<icmp-type>	For ICMP|IP The ICMP type, as defined in RFC792 and RFC950. Specify one of the following integers to create a filter for the ICMP message type:	
	0	Echo replies.
	3	Destination unreachable messages.
	4	Source quench messages.
	5	Redirect (change route) messages.
	8	Echo requests.
	11	Time exceeded messages.
	12	Parameter problem messages.
	13	Timestamp requests.
	14	Timestamp replies.
	15	Information requests.
	16	Information replies.
	17	Address mask requests.
	18	Address mask replies.
`log`	Logs the results.	

Mode Global Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage Use IPv6 extended access-lists to control the transmission of IPv6 packets on an interface, and restrict the content of routing updates. The switch stops checking the IPv6 extended access-list when a match is encountered.

For backwards compatibility you can either create IPv6 extended access-lists from within this command, or you can enter `ipv6 access-list extended` followed by only the IPv6 extended access-list name. This latter (and preferred) method moves you to the `(config-ipv6-ext-acl)` prompt for the selected IPv6 extended access-list number, and from here you can configure the filters for this selected access-list.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Example 1 [creating a list]

To add a new filter to the access-list named `my-list` that will reject incoming ICMP packets from `2001:0db8::0/64` to `2001:0db8::f/64`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list extended my-list
awplus(config-ipv6-ext-acl)# icmp 2001:0db8::0/64 2001:0db8::f/64
```

Example 2 [adding to a list]

To insert a new filter at sequence number `5` of the access-list named `my-list` that will accept ICMP type 8 packets from the `2001:0db8::0/64` network to the `2001:0db8::f/64` network, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list extended my-list
awplus(config-ipv6-ext-acl)# 5 icmp 2001:0db8::0/64
2001:0db8::f/64
```

Example 3 [list with filter]

To create the access-list named `TK` to deny TCP protocols, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list extended TK deny tcp any eq
14 any lt 12 log
```

Related Commands

ipv6 access-list extended proto
(ipv6 access-list extended IP protocol filter)
(ipv6 access-list extended TCP UDP filter)
show ipv6 access-list (IPv6 Software ACLs)
show running-config

ipv6 access-list extended proto

Use this command when configuring an IPv6 extended access-list for filtering frames that permit or deny packets with a specific value based on the IP protocol number specified.

The no variant of this command removes a specified IPv6 extended access-list with an IP protocol number.

Syntax

```
ipv6 access-list extended <list-name>
    {deny|permit} proto <ip-protocol>}
    {<ipv6-source-address/prefix>|any}
    {<ipv6-destination-address/prefix>|any} [log]

no ipv6 access-list extended <list-name>
    {deny|permit} proto <ip-protocol>
    {<ipv6-source-address/prefix>|any}
    {<ipv6-destination-address/prefix>|any} [log]
```

Parameter	Description
<list-name>	A user-defined name for the IPv6 software extended access-list.
deny	Specifies the packets to reject.
permit	Specifies the packets to accept.
proto	The IP Protocol type specified by it protocol number <1-255>.
<ip-protocol>	The IP protocol number, as defined by IANA (Internet Assigned Numbers Authority http://www.iana.org/assignments/protocol-numbers).

<ipv6-source-address/prefix>	IPv6 source address, or local address. The IPv6 address uses the format X:X::X:X/Prefix-Length. The prefix-length is usually set between 0 and 64, or has the value 128.
any	Any source address or local address.

Parameter(cont.)	Description(cont.)
<ipv6-destination-address/prefix>	IPv6 destination address, or local address. The IPv6 address uses the format X:X::X:X/Prefix-Length. The prefix-length is usually set between 0 and 64, or has the value 128.
`any`	Any destination address or remote address.
`log`	Log the results.

Mode Global Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage Use IPv6 extended access-lists to control the transmission of IPv6 packets on an interface, and restrict the content of routing updates. The switch stops checking the IPv6 extended access-list when a match is encountered.

The filter entry will match on any IP protocol type packet that has the specified source and destination IPv6 addresses and the specified IP protocol type. The parameter `any` may be specified if an address does not matter.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Examples To create the IPv6 access-list named `ACL-1` to deny IP protocol `9` packets from `2001:0db8:1::1/128` to `2001:0db8:f::1/128`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list extended ACL-1 deny proto 9
2001:0db8:1::1/128 2001:0db8:f::1/128
```

To remove the IPv6 access-list named `ACL-1` to deny IP protocol `9` packets from `2001:0db8:1::1/128` to `2001:0db8:f::1/128`, use the commands:

```
awplus# configure terminal
awplus(config)# no ipv6 access-list extended ACL-1 deny proto
10 2001:0db8:1::1/128 2001:0db8:f::1/128
```

Related Commands ipv6 access-list extended (named)
(ipv6 access-list extended IP protocol filter)
show ipv6 access-list (IPv6 Software ACLs)
show running-config

(ipv6 access-list extended IP protocol filter)

Use this ACL filter to add a filter entry for an IPv6 source and destination address and prefix, with or without an IP protocol specified, to the current extended IPv6 access-list. If a sequence is specified, the new entry is inserted at the specified location. Otherwise, the new entry is added at the end of the access-list.

The no variant of this command removes a filter entry for an IPv6 source and destination address and prefix, with or without an IP protocol filter entry, from the current extended IPv6 access-list. You can specify the ACL filter entry by entering either its sequence number, or its filter entry profile.

Syntax [ip|proto]

```
[<sequence-number>]
   {deny|permit} {ip|any|proto <ip-protocol>}
   {<ipv6-source-address/prefix>|any}
   {<ipv6-destination-address/prefix>|any} [log]

no {deny|permit} {ip|any|proto <ip-protocol>}
   {<ipv6-source-address/prefix>|any}
   {<ipv6-destination-address/prefix>|any} [log]

no [<sequence-number>]
```

Parameter	Description
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.
deny	Specifies the packets to reject.
permit	Specifies the packets to accept.
ip	IP packet.
any	Any packet.
proto *<ip-protocol>*	The IP Protocol type specified by it protocol number <1-255>.
<ip-protocol>	The IP protocol number, as defined by IANA (Internet Assigned Numbers Authority http://www.iana.org/assignments/protocol-numbers).

<ipv6-source-address/prefix>	IPv6 source address, or local address. The IPv6 address uses the format X:X::X:X/Prefix-Length. The prefix-length is usually set between 0 and 64, or has the value 128.
any	Any source address or local address.

Parameter(cont.)	Description(cont.)
<ipv6-destination-address/prefix>	IPv6 destination address, or local address. The IPv6 address uses the format X:X::X:X/Prefix-Length. The prefix-length is usually set between 0 and 64, or has the value 128.
`any`	Any destination address or remote address.
`log`	Log the results.

Mode IPv6 Extended ACL Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage The filter entry will match on any IP protocol type packet that has the specified source and destination IPv6 addresses and the specified IP protocol type. The parameter `any` may be specified if an address does not matter.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Examples To add a new ACL filter entry to the extended IPv6 access-list named `my-list` with sequence number `5` rejecting the IPv6 packet from `2001:db8:1:1` to `2001:db8:f:1`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list extended my-list
awplus(config-ipv6-ext-acl)# 5 deny ip 2001:db8:1::1/128
2001:db8:f::1/128
```

To remove the ACL filter entry to the extended IPv6 access-list named `my-list` with sequence number `5`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list extended my-list
awplus(config-ipv6-ext-acl)# no 5
```

Related Commands
ipv6 access-list extended (named)
show ipv6 access-list (IPv6 Software ACLs)
show running-config

(ipv6 access-list extended TCP UDP filter)

Use this ACL filter to add a filter entry for an IPv6 source and destination address and prefix, with a TCP (Transmission Control Protocol) or UDP (User Datagram Protocol) source and destination port specified, to the current extended IPv6 access-list. If a sequence number is specified, the new entry is inserted at the specified location. Otherwise, the new entry is added at the end of the access-list.

The no variant of this command removes a filter entry for an IPv6 source and destination address and prefix, with a TCP or UDP source and destination port specified, from the current extended IPv6 access-list. You can specify the filter entry for removal by entering either its sequence number, or its filter entry profile.

Syntax [tcp|udp]

```
[<sequence-number>] {deny|permit} {tcp|udp}
    {<ipv6-source-address/prefix>|any}
    {eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>}
    {<IPv6-destination-address/prefix>|any}
    {eq <destport>|lt <destport>|gt <destport>|ne <destport>} [log]

no {deny|permit} {tcp|udp}
    {<ipv6-source-address/prefix>|any}
    {eq <sourceport>|lt <sourceport>|gt <sourceport>|ne <sourceport>}}
    {<IPv6-destination-address/prefix>|any}
    {eq <destport>|lt <destport>|gt <destport>|ne <destport>} [log]

no <sequence-number>
```

Parameter	Description
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.
deny	Specifies the packets to reject.
permit	Specifies the packets to accept.
tcp	TCP packet.
udp	UDP packet.
<ipv6-source-address/prefix>	IPv6 source address, or local address. The IPv6 address uses the format X:X::X:X/Prefix-Length. The prefix-length is usually set between 0 and 64, or has the value 128.
any	Any source address or local address.
eq	Equal to.
lt	Less than.
gt	Greater than.
ne	Not equal to.
<sourceport>	The source port number, specified as an integer between 0 and 65535.

Parameter(cont.)	Description(cont.)
<ipv6-destination-address/prefix>	IPv6 destination address, or local address. The IPv6 address uses the format X:X::X:X/Prefix-Length. The prefix-length is usually set between 0 and 64, or has the value 128.
<destport>	The destination port number, specified as an integer between 0 and 65535.
`log`	Log the results.

Mode IPv6 Extended ACL Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage The filter entry will match on any packet that has the specified source and destination IPv6 addresses and the specified TCP or UDP source and destination port. The parameter `any` may be specified if an address does not matter.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Examples To add a new filter entry with sequence number `5` to the access-list named `my-list` to reject TCP packets from `2001:0db8::0/64` port `10` to `2001:0db8::f/64` port `20`, use the following commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list extended my-list
awplus(config-ipv6-ext-acl)# 5 deny tcp 2001:0db8::0/64 eq 10
                             2001:0db8::f/64 eq 20
```

To add a new filter entry with sequence number `5` to the extended IPv6 access-list named `my-list` to reject UDP packets from `2001:0db8::0/64` port `10` to `2001:0db8::f/64` port `20`, use the following commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list extended my-list
awplus(config-ipv6-ext-acl)# 5 deny udp 2001:0db8::0/64 eq 10
                             2001:0db8::f/64 eq 20
```

To remove the filter entry with sequence number `5` to the extended IPv6 access-list named `my-list`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list extended my-list
awplus(config-ipv6-ext-acl)# no 5
```

Related Commands

ipv6 access-list extended (named)
show ipv6 access-list (IPv6 Software ACLs)
show running-config

ipv6 access-list standard (named)

This command configures an IPv6 standard access-list for filtering frames that permit or deny IPv6 packets from a specific source IPv6 address.

The no variant of this command removes a specified IPv6 standard access-list.

Syntax [list-name]

```
ipv6 access-list standard <ipv6-acl-list-name>

no ipv6 access-list standard <ipv6-acl-list-name>
```

Parameter	Description
<*ipv6-acl-list-name*>	A user-defined name for the IPv6 software standard access-list.

Syntax [deny|permit]

```
ipv6 access-list standard <ipv6-acl-list-name>
    [{deny|permit}
    {<ipv6-source-address/prefix-length>|any}
    [exact-match]]

no ipv6 access-list standard <ipv6-acl-list-name>
    [{deny|permit}
    {<ipv6-source-address/prefix-length>|any}
    [exact-match]]
```

Parameter	Description
<*ipv6-acl-list-name*>	A user-defined name for the IPv6 software standard access-list.
`deny`	The IPv6 software standard access-list rejects packets that match the type, source, and destination filtering specified with this command.
`permit`	The IPv6 software standard access-list permits packets that match the type, source, and destination filtering specified with this command.
<*ipv6-source-address/prefix-length*>	Specifies a source address and prefix length. The IPv6 address prefix uses the format X:X::/prefix-length. The prefix-length is usually set between 0 and 64, or has the value 128.
`any`	Matches any source IPv6 address.
`exact-match`	Exact match of the prefixes.

Mode Global Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage Use IPv6 standard access-lists to control the transmission of IPv6 packets on an interface, and restrict the content of routing updates. The switch stops checking the IPv6 standard access-list when a match is encountered.

For backwards compatibility you can either create IPv6 standard access-lists from within this command, or you can enter `ipv6 access-list standard` followed by only the IPv6 standard access-list name. This latter (and preferred) method moves you to the `(config-ipv6-std-acl)` prompt for the selected IPv6 standard access-list, and from here you can configure the filters for this selected IPv6 standard access-list.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Example To enter the IPv6 Standard ACL Configuration mode for the access-list named `my-list`, use the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list standard my-list
awplus(config-ipv6-std-acl)#
```

Related Commands
(ipv6 access-list standard filter)
show ipv6 access-list (IPv6 Software ACLs)
show running-config

(ipv6 access-list standard filter)

Use this ACL filter to add a filter entry for an IPv6 source address and prefix length to the current standard IPv6 access-list. If a sequence number is specified, the new entry is inserted at the specified location. Otherwise, the new entry is added at the end of the access-list.

The no variant of this command removes a filter entry for an IPv6 source address and prefix from the current standard IPv6 access-list. You can specify the filter entry for removal by entering either its sequence number, or its filter entry profile.

Syntax [icmp]

```
[<sequence-number>] {deny|permit}
    {<ipv6-source-address/prefix-length>|any}

no {deny|permit}
    {<ipv6-source-address/prefix-length>|any}

no <sequence-number>
```

Parameter	Description
<sequence-number>	<1-65535> The sequence number for the filter entry of the selected access control list.
deny	Specifies the packets to reject.
permit	Specifies the packets to accept.
<ipv6-source-address/prefix-length>	IPv6 source address and prefix-length in the form X:X::X:X/P.
any	Any IPv6 source host address.

Mode IPv6 Standard ACL Configuration

Default Any traffic controlled by a software ACL that does not explicitly match a filter is denied.

Usage The filter entry will match on any IPv6 packet that has the specified IPv6 source address and prefix length. The parameter `any` may be specified if an address does not matter.

Note Software ACLs will deny access unless explicitly permitted by an ACL action.

Examples To add an ACL filter entry with sequence number `5` that will deny any IPv6 packets to the standard IPv6 access-list named `my-list`, enter the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list standard my-list
awplus(config-ipv6-std-acl)# 5 deny any
```

To remove the ACL filter entry that will deny any IPv6 packets from the standard IPv6 access-list named `my-list`, enter the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list standard my-list
awplus(config-ipv6-std-acl)# no deny any
```

Alternately, to remove the ACL filter entry with sequence number `5` to the standard IPv6 access-list named `my-list`, enter the commands:

```
awplus# configure terminal
awplus(config)# ipv6 access-list standard my-list
awplus(config-ipv6-std-acl)# no 5
```

Related Commands

ipv6 access-list standard (named)
show ipv6 access-list (IPv6 Software ACLs)
show running-config

show ipv6 access-list (IPv6 Software ACLs)

Use this command to display all configured IPv6 access-lists or the IPv6 access-list specified by name. Omitting the optional access-list name parameter placeholder will display all IPv6 ACLs.

Use the show ipv6 access-list standard command to display a specified standard named IPv6 access-list that has been defined using the ipv6 access-list standard (named) command.

Syntax

```
show ipv6 access-list [<access-list-name>]
show ipv6 access-list standard <access-list-name>
```

Parameter	Description
`standard`	Named standard access-list.
<access-list-name>	Specify an IPv6 access-list name.

Mode User Exec and Privileged Exec

Example To show the ipv6 access-list specified with the name `acl_name` use the following command:

```
awplus# show ipv6 access-list standard acl_name
```

Output Figure 59-1: Example output from the **show ipv6 access-list** command

```
Named Standard IPv6 access-list name
  deny any
```

Example To show all configured IPv6 access-lists use the following command:

```
awplus# show ipv6 access-list
```

Output Figure 59-2: Example output from the **show ipv6 access-list** command

```
IPv6 access-list deny_icmp
  deny icmp any any vlan 1

IPv6 access-list deny_ssh
  deny tcp abcd::0/64 any eq 22
```

Introduction

This chapter introduces the concept of Quality of Service (QoS) with particular reference to Allied Telesis switches running the AlliedWare Plus™ Operating System. For additional information on using QoS on AT switches see, *How To Configure QoS on x900-24, x900-12, and SwitchBlade x908 Series Switches*. This How To Note is available from http://www.alliedtelesis.com.

The concept of QoS is a departure from the original networking concept of treating all network traffic in the same way. Without QoS, all traffic types are equally likely to be dropped when a link becomes oversubscribed. With QoS, certain traffic types can be given preferential treatment. QoS is therefore a very useful tool both to control congestion and to meter or cap data in order to apply pre-agreed service levels.

Operationally, QoS is applied within the link and network layers. Functionally it provides the capability to intelligently transport your network traffic in order to provide stable and predictable end-to-end network performance.

Business benefits

Quality of Service mechanisms enable:

- network service providers to sell different levels of service to customers, based on what their customers require, and be confident in their ability to guarantee the reliable delivery of these services
- enterprise and educational organizations to actively manage and provide many services across one network, for example live video streaming and standard data services, with preferential treatment being given to mission-critical traffic
- network administrators to manage network congestion as network traffic levels increase and time-critical applications, such as streaming media, become more widely in demand by customers and organizations

QoS Operations

Quality of Service is typically based on how the switch performs the following functions:

- assigns priority to incoming frames (that do not already carry priority information)
- correlates prioritized frames with traffic classes, or maps frames to traffic classes based on other criteria
- correlates traffic classes with egress queues, or maps prioritized frames to egress queues
- provides minimum and maximum bandwidths for traffic classes, egress queues, and/or ports
- schedules frames in egress queues for transmission (for example, empty queues in strict priority or sample each queue)
- re-labels the priority of outgoing frames
- determines which frames to drop or re-queue if the network becomes congested
- reserves memory for switching/routing or QoS operation (for example, reserving buffers for egress queues or buffers to store packets with particular characteristics)

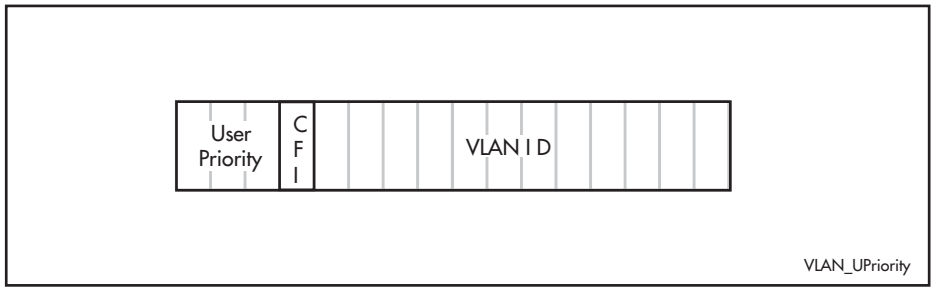
QoS Packet Information

Provision for QoS information to be embedded within the data fields exists within both the data link and network layer protocols. This information can then be used to assess the priority of the data and the resource preferences that need to be applied. The process of applying these service quality tags to your data is known as marking.

Link Layer QoS

Link layer frames entering a port may either be tagged or untagged. VLAN tagged frames contain the additional 802.1Q tag fields shown in Figure 60-1 below. Located within the TCI is a three bit User Priority field. This field is specifically provided to attach QoS based priority information, often referred to as the Class of Service (CoS) field.

Figure 60-1: IEEE 802.1Q Tagging



Appendix G of the IEEE Standard 802.1D provides some useful guidelines on applying priorities to 7 traffic types: These are summarized in the Table 60-1 below:

Table 60-1: CoS Traffic Mapping Guidelines

User Priority	Traffic Types
1	Background
2	Spare
0	Best Effort
3	Excellent Effort
4	Controlled Load
5	Video <100 ms latency and jitter
6	Voice <10 ms latency and jitter
7	Network Control

On the switch you can use the match cos command to select frames that match a particular User Priority value and assign them to a particular class-map. You can then map these incoming frames to one of eight egress queues. This facility enables you to accept frames that are already carrying meaningful priority information and automatically assign them to an appropriate egress queue. For example, you could decide to send frames with a User Priority value of 7 to queue 3, and frames with a User Priority value of 2 to queue 7. The process of assigning queues based on CoS tags is commonly known as “PreMarking”.

Note You configure the pre-marking steps to an ingress port. This process marks the data packets so that when they reach the egress port the decisions made during pre-marking can be applied in accordance with the configuration of the egress port.

Application with VLAN double tagging

Note that if you are using VLAN double tagging, you could use the match cos command to set the individual QoS requirements *within* each client network and also separately within the provider network. You can then use the match inner-cos command to apply particular "*client*" QoS requirements that you want to apply within the provider network. This process applies two levels of QoS within the provider network; one that operates specifically for the network provider, and another that is specific for traffic belonging to selected clients. See "VLAN Double Tagging (VLAN Stacking)" on page 16.5.

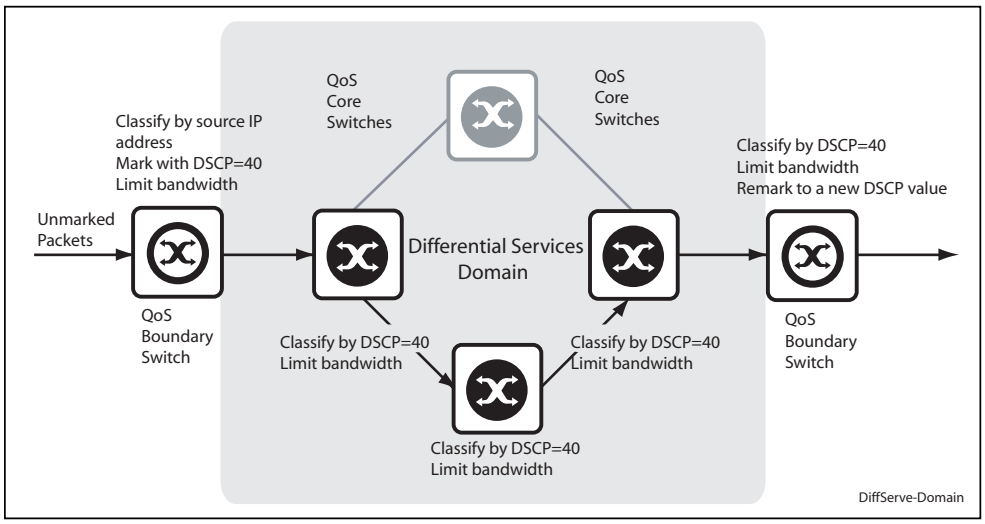
At the network layer IPv4 packets contain an 8 bit field specifically to carry QoS information. This field, defined in RFC 1349, was originally named the Type of Service (ToS) field and contained a *ToS* component and a *Precedence* component. The ToS field however, has since been replaced by the Differentiated Services field.

Differentiated Services Architecture

Whilst a full description of the differential services model is outside the scope of this software reference, a brief introduction is provided. For further information, RFC 2475 provides an in depth definition of the architecture.

The basic differential services model envisages a multi router network within which common service qualities are applied. At the network boundary, *QoS Edge Routers* inspect the traffic and classify it into common service quality groups called Per Hop Behaviors (PHBs). A specific marker value called a Differential Services Code Point (DSCP) is added to the IP header of each packet, which allocates it to a PHB. *QoS Core Routers* within the network can then use the DSCP to decide on an appropriate service quality level to apply. When a network contains a consistently applied differential services code points DSCP it is referred as a Differential Services Domain (often shortened to DiffServe Domain). Figure 60-2 shows a simple Differential Services Domain.

Figure 60-2: Differentiated Services Domain

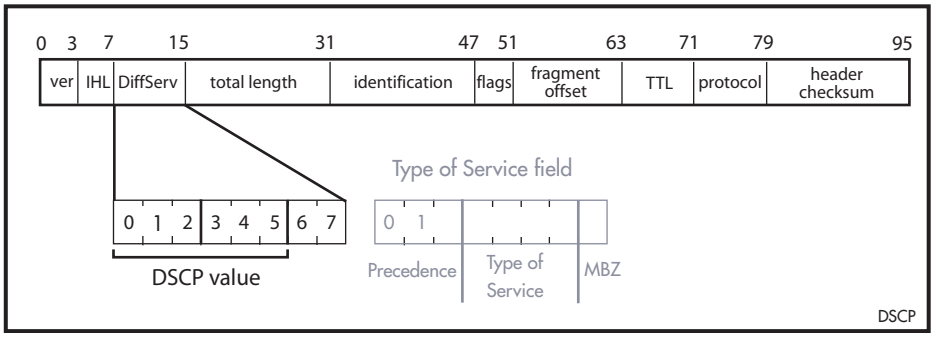


The Differential Services Field

Figure 60-3 shows an IP header containing a Differentiated Services field. The format of this redefined field is explained in RFC 2474; the main difference being that the old ToS field has been replaced by a 6 byte Differentiated Services Code Point (DSCP) field, which now provides for up to 64 defined values.

By applying this model only the QoS edge routers need to fully interrogate the incoming data packets; the QoS core routers are then relieved of this processing task and need only to inspect the DCSP before applying its appropriate forwarding, queueing, and shaping rules.

Figure 60-3: The DSCP bits of the DS field in the IPv4 header



On the switch you can use the match inner-vlan command to select frames containing a particular DSCP value, and associate them with a particular class map and policy map.

You can then use the set queue command to directly map these incoming frames to one of eight egress queues. This facility enables you to accept frames that are already carrying meaningful priority information to be automatically assigned to an appropriate egress queue. For example, you could decide to send frames with a User Priority value of 7 to queue 3, and frames with a User Priority value of 2 to queue 7.

Because the model offers considerable flexibility, and the mapping of traffic types to DCSPs is individual for each network, this locally applied definition is known as a *Differential Services Domain*. The previous section introduced the concept of a Per Hop (service quality) Behaviors or PHBs. RFC 2597 defines a specific PHB group called Assured Forwarding (AF). The AF PHB group provides delivery of IP packets in four independently forwarded AF classes. Within each AF class, an IP packet can be assigned one of three different levels of drop precedence. Table 60-2 shows a list of recommended AF code points.

Table 60-2: Recommended DSCP Code Points

	(Lowest Priority) **Class 1 (001xxxx)**	**Class 2 (010xxxx)**	**Class 3 (011xxxx)**	(Highest Priority) **Class 4 (100xxxx)**
Low Drop Precedence	001010 AF11 Decimal 10	010010 AF21 Decimal 18	011010 AF31 Decimal 26	100010 AF41 Decimal 34
Medium Drop Precedence	001100 AF12 Decimal 12	010100 AF22 Decimal 20	011100 AF32 Decimal 28	100100 AF42 Decimal 36
High Drop Precedence	001110 AF13 Decimal 14	010110 AF23 Decimal 22	011110 AF33 Decimal 30	100110 AF43 Decimal 38

Processing pre-marked packets

A logical question to ask at this point is; how does the QoS switch deal with data that arrives with a pre-existing service level tag such as a DSCP? As previously touched on, the differentiated services model envisages a network that comprises QoS boundary routers at its edge and QoS core routers in its core network.

At the network edge the QoS boundary routers filter the incoming data based on specific packet components. Based on this filtering each packet is assigned a DSCP value. This value will determine the service level - priority, queueing etc - that will be applied.

Within the network core, the packet filtering required is reduced to simply reading the DSCP within each incoming packet, and applying the appropriate set of service levels. This relieves the core routers of the processing overhead of applying complex filtering to its high speed data streams.

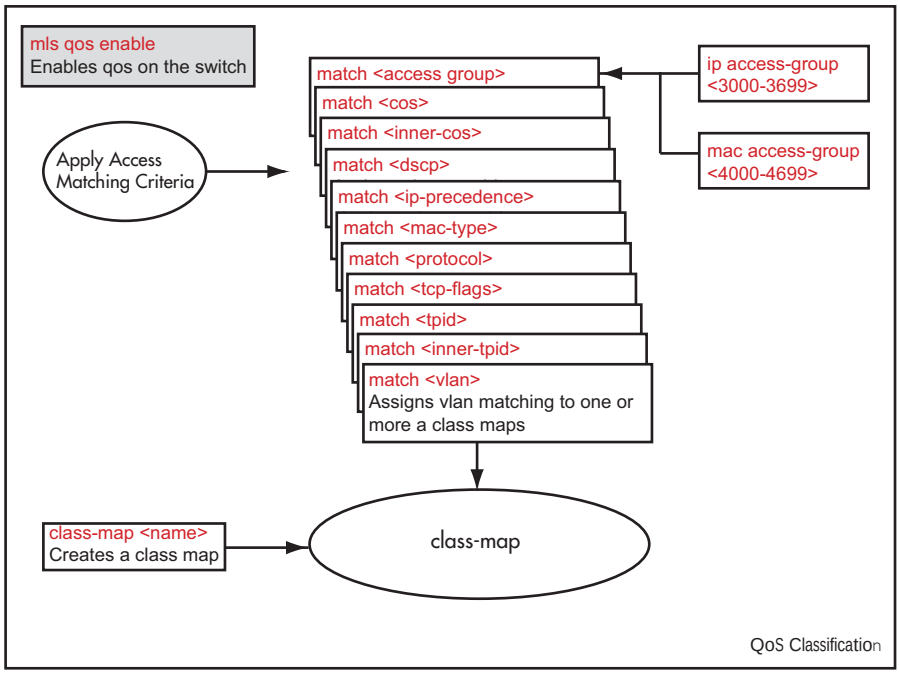
Applying QoS on Your Switch

This section steps you through the various stages of QoS set-up and introduces the QoS commands and how to apply them. Note that before you can configure any QoS functions on your switch, you must first enable QoS by using the mls qos enable command.

Classifying your Data

One of the early steps in setting up QoS on a network is planning and applying your classification rules. Classification is the process of Filtering and Marking. Filtering involves sorting your data into appropriate traffic types. Marking involves tagging the data so that downstream ports and routers can apply appropriate service policy rules. This process is known as premarking. Figure 60-4 illustrates the classifying process, and will be referred to in the examples that follow.

Figure 60-4: QoS Classification Process



At the premarking stage you can assign your data a particular priority level by giving it a link level user priority, see “Link Layer QoS” on page 60.3, or a network level DSCP “Differentiated Services Architecture” on page 60.4. You can also assign the data to a particular output (or egress) queue.

Class Maps

Class Maps are among the pivotal QoS components. They provide the means that associate the classified traffic with its appropriate QoS actions. They are the linking elements for the following functions:

- classification
- policy mapping
- aggregate policing and metering
- pre-marking

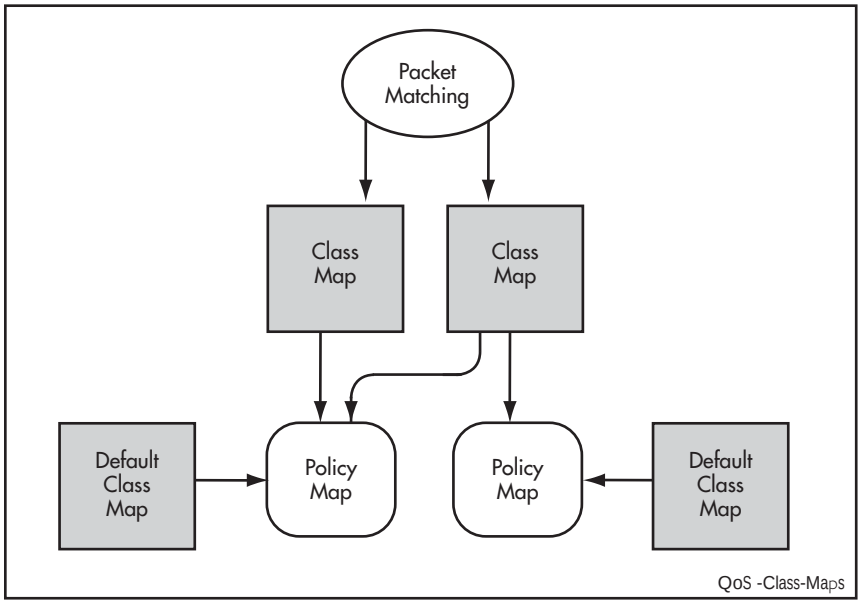
Figure 60-5 shows the relationship between a class-map and its associated functions. Note that the relationship between a class-map and a policy-map can be one-to-one or many-to-one. For information on policy-maps see the section, "Policy Maps" on page 60.10.

Note

If a conflict occurs between the settings in two class maps, priority will be applied to the class map that was created first.

An example of such a conflict is the arrival of a packet that meets the classification requirements of two class maps each configured to the same policy map and set to apply different priority settings to the packet.

Figure 60-5: Relationship between a class map and its associated functions



Creating a class-map

To create a class map, use the class-map command on page 61.4.

This example creates a class-map called `video-traffic` and another called `data-traffic`:

```
awplus# configure terminal
awplus(config)# class-map video-traffic
awplus(config-cmap)# exit
awplus(config)# class-map data-traffic
awplus(config-cmap)#
```

Creating and configuring default class-maps

These (automatically created) default class-maps serve as the means to specify the action that will apply to all unclassified data, i.e. all data within a policy-map that is not captured by any of the applied match commands that are applied to the policy-map by its class-maps.

Each time a new policy-map is created a new class map called "default" is also automatically created and assigned to the new policy map. You can configure any of the default class maps by using the default-action command on page 61.6

To set the default class-map for the policy-map `p-map1` to have the action of `deny`:

```
awplus# config
awplus(config)# policy-map p-map1
awplus(config-pmap)# default-action deny
```

Applying a match command to a class-map

To apply a matching filter to a class map use one of the match commands.

This example creates a filter to select VLAN 5 traffic and applies this filter to the class map named `video-traffic`.

```
awplus# config terminal
awplus(config)# class-map video-traffic
awplus(config-cmap)# match vlan 5
```

Associating a class-map with a policy-map

To associate a class map with a policy map, use the class command on page 61.3.

Note A maximum of 128 class maps may be attached to each policy map.

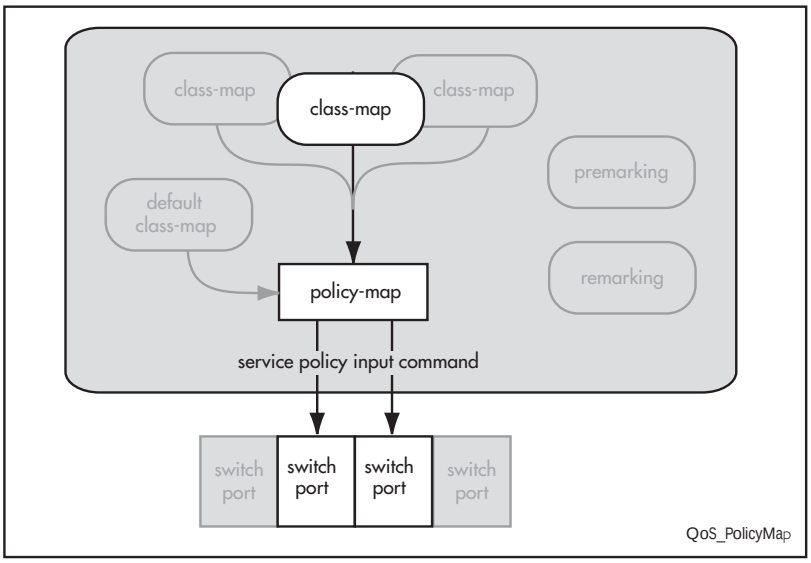
The following example creates a policy map called `policy-one`, and associates it with the class-maps named `video-traffic`, and `database-traffic`:

```
awplus# configure terminal
awplus(config)# policy-map policy-one
awplus(config-pmap)# class video-traffic
awplus(config-pmap-c)# exit
awplus(config-pmap)# class database-traffic
awplus(config-pmap-c)#
```

Policy Maps

Policy maps are the means by which you apply your class-map properties to physical switch ports. Figure 60-8 on page 60.17 illustrates this concept. Note that whilst a policy map can be assigned to several ports, a port cannot have more than one policy-map assigned to it.

Figure 60-6: Policy Maps and Related Entities



To create and name a new policy map you use the policy-map command on page 61.53.

To create a policy-map called `pmap1` use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
```

Having created the policy map `pmap1` we can use the class command on page 61.3 to assign it to one or more class maps. Since we created the class-maps `video-traffic` and `office-traffic` earlier in this chapter, we can now attach the policy-map `pmap1` to both class-maps.

Use the class command to assign the policy map `pmap1` to the class-maps `video-traffic` and `office-traffic`:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class video-traffic
awplus(config-pmap-c)# exit
awplus(config-pmap)# class office-traffic
awplus(config-pmap-c)#
```

Premarking Your Traffic

Premarking relates to adding QoS markers to your incoming data traffic before it is metered (policed). Network switches will often be configured with two different premarking profiles, one for the QoS edge switches and another for the QoS core switches. This situation would apply if you are operating DSCP domains.

QoS markers can be applied at both the link layer (within the CoS field), and at the network layer (within the DSCP field). For more information on this topic see "QoS Packet Information" on page 60.3.

For boundary QoS switches

Traffic entering QoS boundary switches is unlikely to contain pre-existing QoS tagging. In this case, you can apply one or more of the following QoS mapping options.

- Assign an output queue to data associated with a particular class-map, using the set queue command, and apply it to the input (ingress) port.
- Assign a CoS tag to data associated with a particular class-map using the set cos command. You can then map the CoS tag to an output (egress) port queue (using the mls qos map cos-queue to command).
- Assign a DSCP tag to data associated with a particular class-map using the set dscp command. Alternatively, you can use the trust dscp (XEM-2XP) command to map the DSCP tag to an egress port queue, a CoS value, or both. At the premarking stage you can set this mapping using the mls qos map premark-dscp to command. After policing, you can then use the remarking command mls qos map policed-dscp to in order to reassign a particular DSCP to a specific egress queue, CoS value, or both.

When no other mapping is set, all traffic is sent to the queue that is set by the mls qos queue command. If this command is unset (i.e. in the absence of any other queue selection) and the packet is untagged, traffic will be sent to queue 2.

For core QoS switches

Traffic entering ports within the QoS core network will almost certainly contain some pre-existing QoS tagging. Where this is the case, you can apply one of the following QoS mapping options.

- Map the CoS tag to an egress queue. You can do this either for the whole switch or for specific ports via their assigned policy-maps. See "CoS to egress queue premarking" on page 60.11.
- Map the DSCP tag to an output queue. You can do this either for the whole switch or for specific ports via their assigned policy-maps. When no other mapping is set, all traffic is sent to the queue that is set by the mls qos queue command.
- Remap incoming data DSCP or CoS tags to values that are more appropriate for a particular switch or network.
- Assign bandwidth classes for your packets, based on the incoming DSCP. See Setting the Trust DSCP Map command on page 60.14.

CoS to egress queue premarking

If you are using CoS tagging for your QoS functions, your traffic is likely to be either entering the switch with a pre existing CoS tag, or will have appropriate tags attached via your class-maps and policy-maps. You can now mark the data for a particular egress queue, which will take effect when the data reaches its output port. There are two fundamental methods of applying CoS tagged packets to egress queues:

1. Apply a global mapping of CoS tags to egress queues for all ports.

2. Apply a CoS to egress queue mapping for the class-map / policy-map. This mapping - which forms part of the policy map - is applied at an input port, but will take effect at the packet's destination output port. Note that this procedure takes priority over that described in method (1) above.

These methods and their related commands will be now be described in greater detail.

CoS tagging commands

Three commands can be used set or change the CoS tag mapping. Table 60-3 shows the commands that can set or change the CoS tag within a packet.

Table 60-3: CoS Mapping Commands in Hierarchical Order

Command	Function
set cos	Assigns a CoS tag to a particular class-map / policy map.
mls qos map premark-dscp to	Where a packet contains CoS tag and a DSCP tags. The table set by this command contains a configurable DSCP to CoS tag mapping.
mls qos map policed-dscp to	Finally, the remarking function applied by this command can remap all previously set CoS tagging.

Where a packet entering a port contains a pre-existing DSCP, You can use the command mls qos map policed-dscp to change the following components, DSCP tag, CoS tag, bandwidth class.

Note

Where a packet contains both a CoS and a DSCP field, and each field maps to a different class-map; the switch will apply a priority based on the creation date of the class maps to which they apply - the earlier the creation date, the higher the priority

Mapping CoS tags to traffic types

The command mls qos map cos-queue to, enables you to create a switch-wide mapping of CoS values to egress queues. The default mappings for this command are:

```
COS :            0 1 2 3 4 5 6 7
--------------------------------
QUEUE:           2 0 1 3 4 5 6 7
```

These mappings match the CoS guidelines documented in Annex H.2 of ANSI/IEEE 802.1D 1988 Edition. Table H-15 on page 355 of the standard, shows a table of user priorities for specific traffic types. Table 60-4 shows an adapted version of the ANSI/IEEE table.

Table 60-4: Traffic Type Guidelines

User Priority (egress queue)	CoS Value	Acronym	Traffic type	Internal Traffic Queue Defaults
0 (lowest)	1	BK	Background	
1	2	-	Spare	
2	0	BE	Best Effort	Default
3	3	EE	Excellent Effort	

Table 60-4: Traffic Type Guidelines(cont.)

User Priority (egress queue)	CoS Value	Acronym	Traffic type	Internal Traffic Queue Defaults
4	4	CL	Controlled Load	
5	5	VI	"Video," <100 ms latency and jitter	
6	6	VO	"Voice," <10 ms latency and jitter	EPSR-Management BPDU ARP-Requests
7 (highest)	7	NC	Network Control	Stack Management

CoS settings for VCStack stack operation

In general you can apply the same principles when configuring QoS on a VCStack as you would for single switch; however there are a few specific changes that you will need to make.

Switches within a VCStack, exchange their stack management information and user data over their high speed inter-stacking links. The stack management information is pre-assigned to the egress queue 7. This is the highest value queue, and (in a stacked configuration) its traffic should not be shared with any user data. However, any CoS tagging of 7 applied to the incoming data will automatically be assign to queue 7 as it crosses the internal stacking links. You will therefore need to reconfigure your CoS to Queue settings to ensure that no user data is sent to queue 7.

To prevent this from happening, we recommend that you make appropriate changes to your queue settings (mappings) to reflect the stacking requirement previously described. For more information on this topic, see "Mapping CoS tags to traffic types" on page 60.12.

This process should include (but not be limited to) running the following command to ensure that any remaining user still carrying a CoS 7 tag, will be mapped to egress queue 6.

To remap priority CoS traffic to egress queue 6, run the following command.

```
awplus# config terminal
awplus(config)# mls qos map cos-queue 7 to 6
```

DSCP to egress queue premarking

If you are using DSCP tagging for your QoS functions, your traffic is likely to be entering the switch either with a pre existing DSCP tag, or will have appropriate DSCP tags attached via your class-maps and policy-maps. You can now mark the data for a particular egress queue, which will take effect when the data reaches its output port.

If your switch forms part of a DSCP domain, you can adapt the steps in this section to apply the mappings and settings to match the standards you have selected for the domain. This mapping - which forms part of the policy map - is applied at an input port, but will take effect at the packet's destination output port.

DSCP to egress queue premarking commands

A number of commands can be used for mapping DSCP tags. Where these conflict, the switch applies a pre-defined set of priorities. Table 60-5 lists these priorities in order (lowest priority first).

Where a packet that contains both CoS and a DSCP fields and each field maps to a different class-map / policy-map, the switch will apply a priority based on the creation date of class maps - the earlier the creation date, the higher the priority priorities.

Table 60-5: DSCP Mapping Commands in Hierarchical Order

Command	Function
mls qos map policed-dscp to	This remarking function can remap previously set dscp values and queue selections.
set dscp	With the trust dscp set, this command will change the dscp value in the packet.
mls qos map premark-dscp to	With the trust dscp set, this command applies a remapping table whose values include the dscp and egress queues.
mls qos queue	Sets a default egress queue for each individual port (or range of ports) on the switch.

If no overriding commands have been configured, and there is no CoS value in the packet, then the default setting of the mls qos queue command will send all data out via its port's egress queue 2. You can use the mls qos queue command to reset the egress queue for each port on the switch. If the packet does contain a CoS tag value, then this queue will be that shown in the mapping in the section "Mapping CoS tags to traffic types" on page 60.12.

Setting the Trust DSCP Map

The Trust DSCP mapping table assigns a new set of QoS values for a DSCP value supplied as table input. To configure this table you use the mls qos map premark-dscp to command.

Table 60-6: Drop Probability Table

Table Input	---------- Table Output ----------			
Existing DSCP	New DSCP Value	New CoS Value	New Queue No	New BW Class green yellow red

The Trust DSCP map provides the highest priority of all the pre-marking controls. To apply this table you must first apply the trust setting by using the trust dscp or trust dscp (XEM-2XP) commands.

At this point the DSCP input to the table will be that existing in the incoming packet. However, by setting the set dscp command you can change the DSCP for all packets within the specified class-map or policy-map (for XEM-2XP) specified. Note, that with the trust DSCP set, the DSCP value that is used for table lookup will depend on the applied port's platform type:

- on switch ports belonging to a XEM-2XP lookup is on the DSCP of the incoming packet.
- on switch ports other than the XEM-2XP, lookup is on either the DSCP of the incoming packet, or the DSCP applied to the selected class-map (i.e. that set by the set dscp command).

Policing (Metering) Your Data

Once you have set-up your classification and created your class-maps, you can start conditioning your traffic flows. One tool used for traffic conditioning is the policer (or meter). The principle of policing is to measure the data flow that matches the definitions for a particular class-map; then, by selecting appropriate data rates, allocate the flows into one of three categories: Red, Yellow, or Green. You then decide what action to apply to the Red, Yellow and Green data.

Two metering types can be configured from the mls qos aggregate-police action command on page 61.23, these types are:

- single-rate three-color
- twin-rate three-color

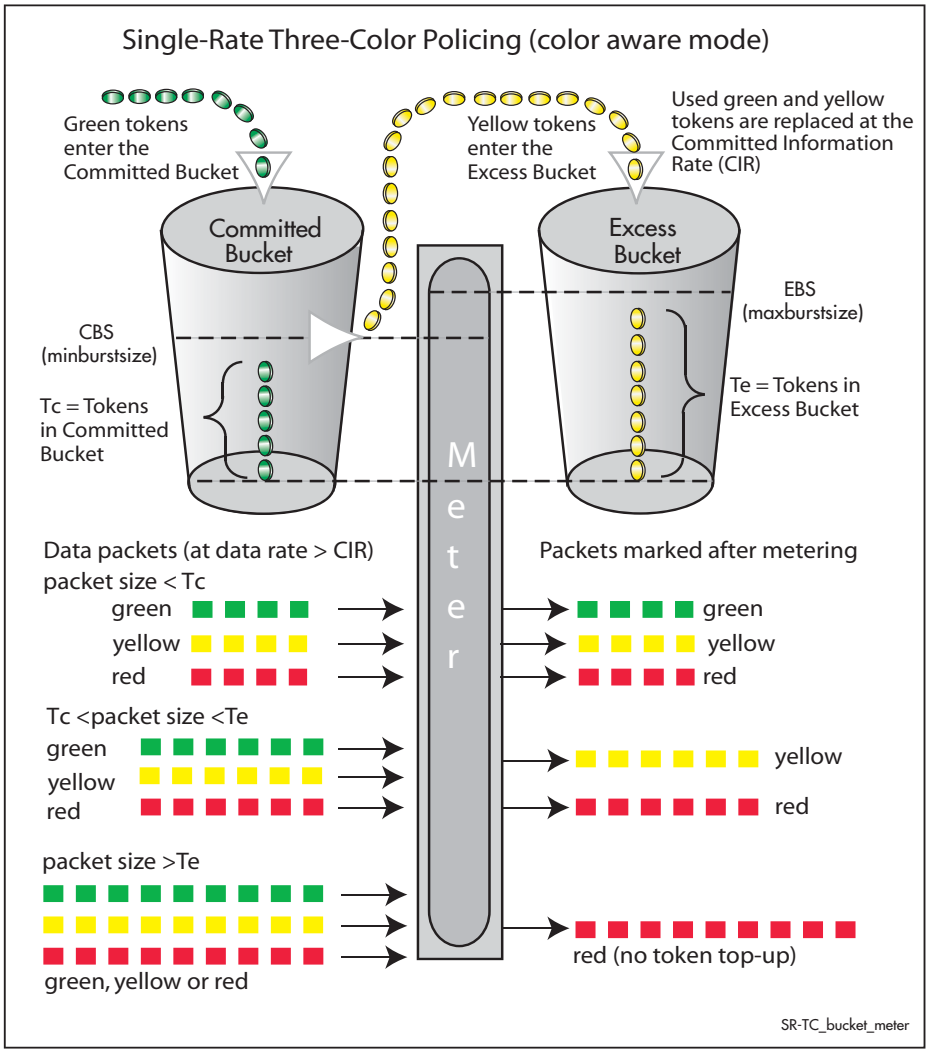
Note that the although the color marking process is carried out on the input port (on ingress), the egress port can also use this color marking to modify its output data flows. The meter operates in the color aware mode; however the premarker that precedes it senses all input data as being green. Note that all external data entering a switch port is considered to be marked green. This means that unless you have re-colored your data at the premarking stage - by using the set bandwidth-class command on page 61.56 - the data entering the meter will be green.

The metering levels, CIR, CBS etc are defined within a policer. This class-map (along with others) is then added to a policy-map, which in turn is attached to a port.

Single-rate Three-color Policing

This policing method is based on that defined in RFC 2697. The principle of single-rate three-color policing is shown in Figure 60-7. For a given class-map, a meter monitors both the token count in the buckets, and the input data flow.

Figure 60-7: Single-rate Three-color Policing



Each byte entering the meter is paired with a token in one of the buckets, and a token is removed as each byte is accepted. If the input data rate is the same as the CIR then the data passes through the port at the same rate as its bucket fills. Hence the bucket level remains constant. In this model, the data buffer is represented by two data buckets. You can specify the CIR using the police single-rate action command.

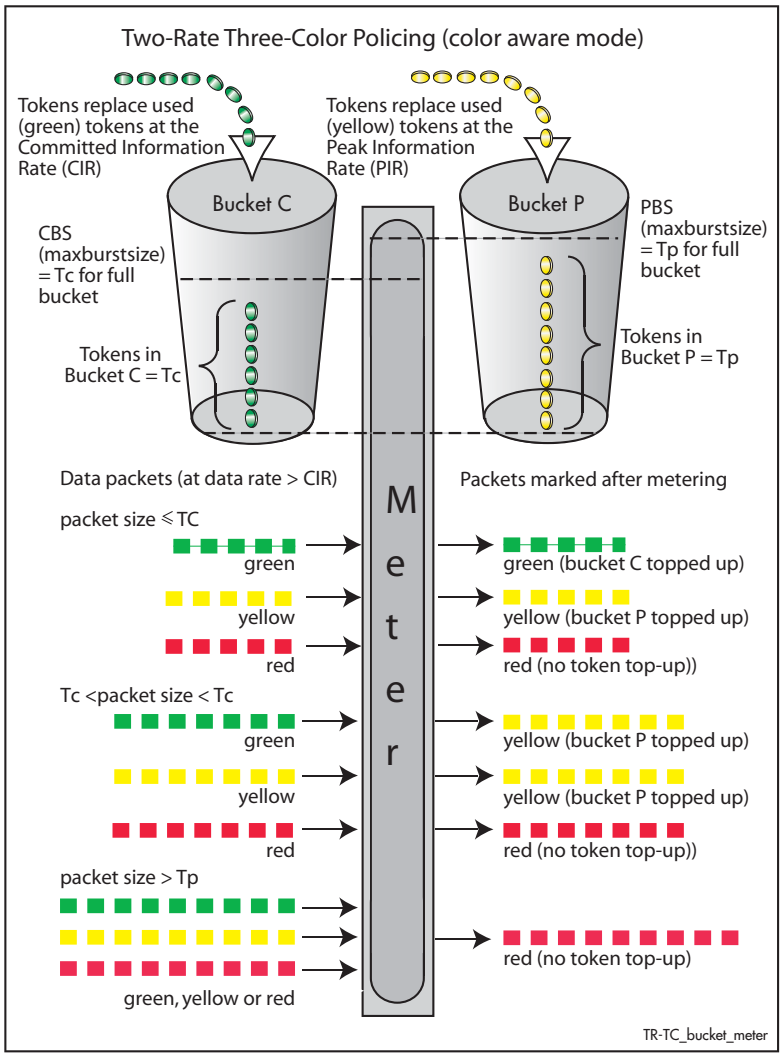
Initially both buckets have their full token count. A surge of date exceeding the CIR will begin to empty the bucket. As the data and tokens are paired, data bytes that match tokens below the CBS level are marked green, those that are between CBS and EBS will be marked yellow, and those that are above EBS are marked red.

Note that although the data is metered per byte, the color marking process is applied per packet. This means that if there were only sufficient tokens available to match part of a packet, then the whole packet would be marked red. Then, depending on the action parameter of the police single-rate action command, the whole packet will be either dropped or forwarded. In either situation, the red marked packet will leave the bucket counts unchanged.

Two-rate Three-color Policing

This policing method is based on that defined in RFC 2698. The principle of two-rate three-color policing is shown in Figure 60-8.

Figure 60-8: Two-rate Three-color Policer



For a given class-map, the meter monitors the token count in both buckets, and the input data flow. Initially tokens enter both buckets until full. As the data enters a port, the meter pairs each byte to a token in one of the buckets, then removes a token from the appropriate bucket. Bucket C is topped up with tokens at the Committed Information Rate (CIR), and bucket P is topped up at the Peak Information Rate (PIR).

When data enters the port at the CIR, the bucket fills at the same rate as the incoming data, thus the token count in bucket C remains constant. Similarly, if data enters the port at the PIR, then the token count in bucket P remains constant. You can specify the CIR and the PIR by using either the police twin-rate action command or the mls qos aggregate-police action command. The function of each of these commands is explained in the section "Configuring and Applying a Policer" on page 60.18.

A surge of data exceeding the CIR will begin to empty bucket C. If bucket C empties to a point where it has insufficient tokens to match to an incoming data packet, then the data packet will be marked yellow. The data will now be measured against the level in bucket P and tokens will be removed from this bucket to match the incoming data. If the incoming data rate drops to less than the CIR then the data will continue to be marked yellow until the level in bucket C has had a chance to fill, whereupon it will be marked *green*.

If the incoming data is greater than the PIR, then bucket P begins to empty. If bucket P empties to a point where it has insufficient tokens to match to an incoming data packet, then the data packet will be marked *red*. In this situation no tokens are removed from either bucket.

Note that although the data is metered per byte, the color marking process is applied per packet. This means that if there were only sufficient tokens available to match part of a packet, then the whole packet would be marked red. Then, depending on the action parameter of the police twin-rate action command, the whole packet will be either dropped, or marked and forwarded. In either situation, the red marked packet will leave the bucket counts unchanged.

Configuring and Applying a Policer

The previous section showed how the policer works and how to select either the single rate or twin rate action. There are two methods to apply a policy to class maps.

1. Select your policy-map and class-map from the command prompt, then enter either the police single-rate action command or the police twin-rate action command whilst selecting the appropriate command parameters.

   This will apply the command to the selected class-map. By running this command several times, each for a different class-map, you can apply separate meter settings to each class-map.

2. Use the mls qos aggregate-police action to create a “named” aggregate policer whilst selecting the appropriate command parameters. Once you have done this, you can use the police-aggregate command to apply the aggregator to the policy-map and class-map selected from the command prompt. Note that you cannot apply an aggregate policer to a class map that has already been attached to a policer by using either the police single-rate action, or the police twin-rate action commands.

The main difference between these two methods is that you use method (1) to apply policing to a number of class-maps, each having its own individually configured meter settings; whereas you use method (2) to apply policing to a number of class-maps and police them all using a single meter setting.

Note A set of class-maps that contribute traffic into a given aggregate policer can belong to different policy-maps. This means that the aggregate policer can meter packets destined for different egress ports.

Remarking Your Data

The remarking process enables you to change the QoS tagging and queue assignments etc from data that has already been marked by the policer. To do this you fill entries in the remarking table by using the mls qos map policed-dscp to command on page 61.32. In order to remark your data ensure that the action parameter of either the police single-rate action or the police twin-rate action is set to policed-dscp-transmit.

The following table shows the remarking options

Table 60-7: Remarking Options

Existing DSCP	BANDWIDTH CLASS		
	Green	Yellow	Red
DSCP value in the packet leaving the meter	New value for DSCP New value for CoS Tag New bandwidth class (Red, Yellow, or Green) New value for egress queue	New value for DSCP New value for CoS Tag New bandwidth class (Red, Yellow, or Green) New value for egress queue	New value for DSCP New value for CoS Tag New bandwidth class (Red, Yellow, or Green) New value for egress queue

Example Traffic whose existing DSCP value is 15 and has its data marked either Green, Yellow or Red is to be remarked to have its existing policed green traffic tagged as follows:

- new DSCP of 20
- new CoS of 3
- new queue of 4
- new bandwidth class of yellow

Table 60-8: Remarking Table Example

DSCP	BANDWIDTH CLASS		
	Green	Yellow	Red
Existing dscp = 1	Remapping for DSCP 1	Remapping for DSCP 1	Remapping for DSCP 1
. . .	Remapping for DSCPs 2 to 14	Remapping for DSCPs 2 to 14	Remapping for DSCPs 2 to 14
Existing dscp =15	New DSCP = 20 New CoS Tag = 3 New bandwidth class = Yellow New egress queue = 4		
. . .	Remapping for DSCPs 2 to 62	Remapping for DSCPs 2 to 62	Remapping for DSCPs 2 to 62
Existing dscp = 63	Remapping for DSCP 63	Remapping for DSCP 63	Remapping for DSCP 63

To configure this setting, you would enter the following commands:

```
awplus# config terminal

awplus(config)# mls qos map policed-dscp 15 bandwidth-class
green to new-dscp 20 new-cos 3 new-queue 4
new-bandwidth-class yellow
```

Configuring the Egress Queues

Previous sections have explained the ingress functions. These include, how the incoming data can be classified and marked according to its priority and allocated to an egress queue, then finally how metering and remarking is applied. At this point the data then flows across the switch to its destination egress port where its transit to the egress queues is controlled.

The means by which data is applied to the egress queues is dependant on three functions:

- Egress queue and QoS markers that are set within each data packet
- Egress controls that are applied to the whole switch
- Egress that are applied to each individual switch port

Fabric queues - The Internal Paths

Although the internal hardware functions of the switch are outside the scope of this manual, the section, "QoS and the Switching Fabric" on page 60.34 provides some background information to help you understand and use the mls qos fabric-queue command. Basically, the internal path that links the fabric adaptors terminates in four fabric queues. These queues schedule the data between the internal fabric adaptors and each port's egress queue.

The mls qos fabric-queue command, mentioned above, enables you to select the scheduling algorithm to be either strict priority, or weighted round robin (WRR). Use the show mls qos fabric-queue to see the present settings on your switch.

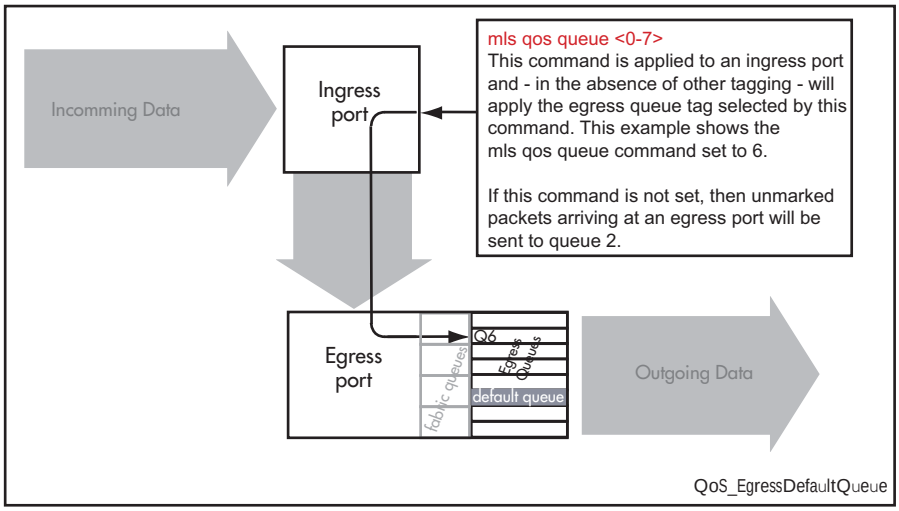
The mls qos fabric-queue command enables you to map the egress queues to 4 internal processor fabric queues. The commands section provides more information such as their default settings and how to reconfigure them.

Egress Queues and QoS markers

Once the data packets have been appropriately filtered, classified, policed, and remarked, they travel across the switch's internal paths carrying their assigned QoS tag markers such as their priority, class and destination queues. For more details on ingress data marking, refer to the earlier sections of this chapter. At the egress port these markers are read and used to determine which queues each data packet will be forwarded to, and the priorities that will be applied.

There are eight egress queues allocated to each egress port. The egress queue that a particular packet passes through is determined by either the configuration of the switch, or the markers contained within the packet itself.

Figure 60-9: Default Egress Queue



Egress Queue Commands Hierarchy

The destination queue that any one packet will take depends on the markers within the packet, and the way the queueing commands have been set. Also, some queueing commands will override others. Here is how the switch prioritizes its queueing commands.

Imagine a packet entering an ingress port then traveling through the switch fabric to reach its appropriate egress port. In this situation the following hierarchy will apply:

1. If the packet enters an egress port carrying no QoS markers and no QoS queueing commands have been set on the switch, then the packet will exit the port via queue number 2.

2. If the packet containing CoS marker arrives at an egress port, then with no other configuration applying, then its queue mapping will be subject to the setting of the mls qos map cos-queue to command.

3. Situations (1) and (2) can be overridden by the mls qos queue command. This command sets a default queue for each switch port.

4. If the set queue command has been applied to specific ports via its class-map / policy map combination, then the queue mapping of this command will override that set by the mls qos queue command for those specific ports.

5. If the trust dscp (XEM-2XP) then the egress queue assignment will be based on the entries in the mls qos map, which is set by the mls qos queue command. This mapping table will override all the previous commands in this list.

6. Finally all the above mappings may be modified by the remarker, by using the mls qos map policed-dscp to command.

Egress Queue Shaping

This section is concerned with how the egress queues are cleared. It does NOT apply to ports on the XEM-2XP module.

There are two aspects to queue shaping:

- Scheduling (strict priority or weighted round robin)
- Drop Mode (tail-drop or weighted early discard)

Scheduling

The scheduler determines how packets in the eight egress port queues are serviced. Two servicing methods can be applied:

- strict priority
- weighted round robin

Strict priority servicing

By default, all queues on all ports are serviced in a strict priority order. This means that the highest numbered priority queue (queue 7) is emptied first; then when it is completely empty, the next highest priority queue is processed, and so on. Thus, for a strict priority queue to be processed, all higher priority queues must be empty.

Strict priority servicing is the default setting; however if your system is configured for weighted round robin (WRR), you can return it to priority queueing by using the commands shown in the following example.

To return queue 3 of `port1.0.1` from WRR servicing to strict priority queueing, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# priority-queue 3
```

Weighted round robin servicing

Two round robin groups can be configured. Using this configuration, all packets in group 1 are serviced first, using the weights specified for the group 1 queues. Once all queues in group 1 are empty, the queues in group 2 are serviced using the weights specified for the group 2 queues. Note that if some queues on the port have also been configured for strict priority, the strict priority queues must be empty before the first weighted round robin group will be serviced.

Example To configure wrr-queue group 1 applying a weighting value of 6 to queues 0 1 2:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# wrr-queue group 1 weight 6 queues 0 1 2
```

Example To configure wrr-queue group 2 applying a weighting value of 12 to queues 3 4 5:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# wrr-queue group 2 weight 12 queues 3 4 5
```

Example In this example port 1.0.1 has queues configured as follows:

- queues 6 and 7 are configured strict priority
- queues 3, 4 and 5 are WRR group 1 with weighting values of 6, 6 and 12 respectively
- queues 0, 1 and 2 are WRR group 2 all with a weighting value of 6

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# priority-queue 6 7
awplus(config-if)# wrr-queue group 1 weight 6 queues 3 4
awplus(config-if)# wrr-queue group 1 weight 12 queues 5
awplus(config-if)# wrr-queue group 2 weight 6 queues 0 1 2
```

In this example, the queues are processed as follows:

1. Queue 7 is processed first.
2. If queue 7 is empty, Queue 6 is processed next.
3. If queues 6 and 7 are empty, queues 3, 4 and 5 are processed with a ratio of 1:1:2.
4. If queues 4 to 7 are empty, queues 0, 1 and 2 are processed with equal weighting.

Drop Mode

Note that this section does not apply to ports on the XEM-2XP

The drop mode sets the limits for packets in the eight egress queues and determines how packets will be dropped if the queues become congested. Two drop methods may be employed, these are:

- Tail Drop
- Weighted Random Early Discard (WRED)

For both the above methods there are 4 pre-existing queue-sets numbered 1-4. You can configure each queue-set with a separate drop mode profile for each of the 8 egress queues.

Your switch has 4 pre-existing queue-sets, one pre-configured for 1G ports and another for 10 G ports. These configurations are shown in Table 60-10 on page -26 and Table 60-11 on page -27. You can name and reconfigure these profiles and change the association of queue sets to switch ports. These steps are explained later in this section.

Note

The default drop mode operation is Tail Drop. In this situation the value set by the mls qos queue-set drop-probability command is ignored, and a drop value of 0 (i.e 100%) is internally applied. Also the value set for the minimum threshold is ignored, and the averaging factor is replaced by an instantaneous comparison of queue size with the maximum threshold figure (Maxth).

Figure 60-10: Queue-Set Defaults for 1G Ports

```

  Queue 5: 9
  Queue 6: 9
  Queue 7: 9
```

Assigning a queue-set description

You can use the mls qos queue-set description command to assign each of the queue-sets with an appropriate description. For example, you could name your triple-play traffic “Triple-Play” as shown below. You could then assign appropriate profiles for each of 8 triple-play queues within the queue-set.

Example To set the description for queue-set 4 to be “Triple-Play,” use the command:

```
awplus# config terminal
awplus(config)# mls qos queue-set 4 description "Triple-Play"
```

Once you have configured your queue-sets, you can apply each to specific ports by using the mls qos queue-set command. You also use this command to select the drop-mode to apply.

Note the following rules when applying queue-sets to queues and ports:

- a port can only have one queue-set applied to it
- a queue-set can be applied to many ports

Example To set port 1.0.1 to use queue-set 2 in random-detect mode, use the command:

```
awplus# config terminal
awplus(config)# interface port1.0.1
awplus(config-if)# mls qos queue-set 2 random-detect
```

Tail Drop

Note that this section does not apply to ports on the XEM-2XP

In this drop mode each egress queue is configured with a maximum threshold value. This value represents the point where the egress buffer queues are full and the egress port must start dropping data. The port does this by dropping data packets destined for the full queue on a “last in first dropped” basis. This enables the port to clear its data already queued for egress.

If a “reliable” transport protocol, such as TCP is used, this data should be retransmitted, but at a slower rate due to lack of returning “acknowledgements”. The queue threshold value is set using the mls qos queue-set threshold command.

Tail drop is far simpler to configure than its alternative random-detect (RED) and in most situations offers similar performance. In some situations, such as when using the UDP protocol, it is more appropriate to use tail-drop than RED. This is because UDP (unlike TCP) is not a sliding window protocol. UDP is also a popular protocol for “real time” data such as voice and video conferencing. The defaults for tail-drop are shown in Figure 60-10 on page 60.26 and Figure 60-11 on page 60.27.

Note The default drop mode operation is Tail Drop. In this situation the value set by the mls qos queue-set drop-probability command is ignored, and a drop value of 0 (i.e 100%) is internally applied. Also the value set for the minimum threshold is ignored, and the averaging factor is replaced by an instantaneous comparison of queue size with the maximum threshold figure (Maxth).

To reset a port from RED drop-mode to tail drop mode, use the mls qos queue-set command.

Example To set port 1.0.1 to tail-drop to use the command:

```
awplus# config terminal
awplus(config)# interface port1.0.1
awplus(config-if)# mls qos queue-set 2 taildrop
```

Random Early Detection (RED)

Note that this section does not apply to ports on the XEM-2XP

This drop mode was developed as a more graceful way of managing queue congestion than that obtained using the tail-drop method described in the previous section. RED is however far more complex to configure than tail-drop. As previously mentioned, in some situations, such as when using the UDP protocol, it is more appropriate to use tail-drop than RED. This is because UDP (unlike TCP) is not a sliding window protocol and so dropping packets does nothing to slow the incoming data flow. Because UDP is also a popular protocol for "real time" data such as voice and video conferences, dropping packets as the egress queue fills, can result in unnecessary performance degradation of the end-user application.

AlliedWare Plus™ enables you to create different RED curves for each traffic class. This feature is known as Weighted Random Early Detection (WRED).

The defaults for WRED configuration are shown in Figure 60-10 on page 60.26 and Figure 60-11 on page 60.27.

Random early detection operates in a similar way to tail drop but begins to (gracefully) drop packets as the *average queue length*[1] approaches the Maximum threshold point (Max_{th}). The concept is illustrated in Figure 60-12 on page 60.30. This figure shows how packets in the three classes, Red, Yellow, and Green are progressively dropped as their egress queue begins to fill.

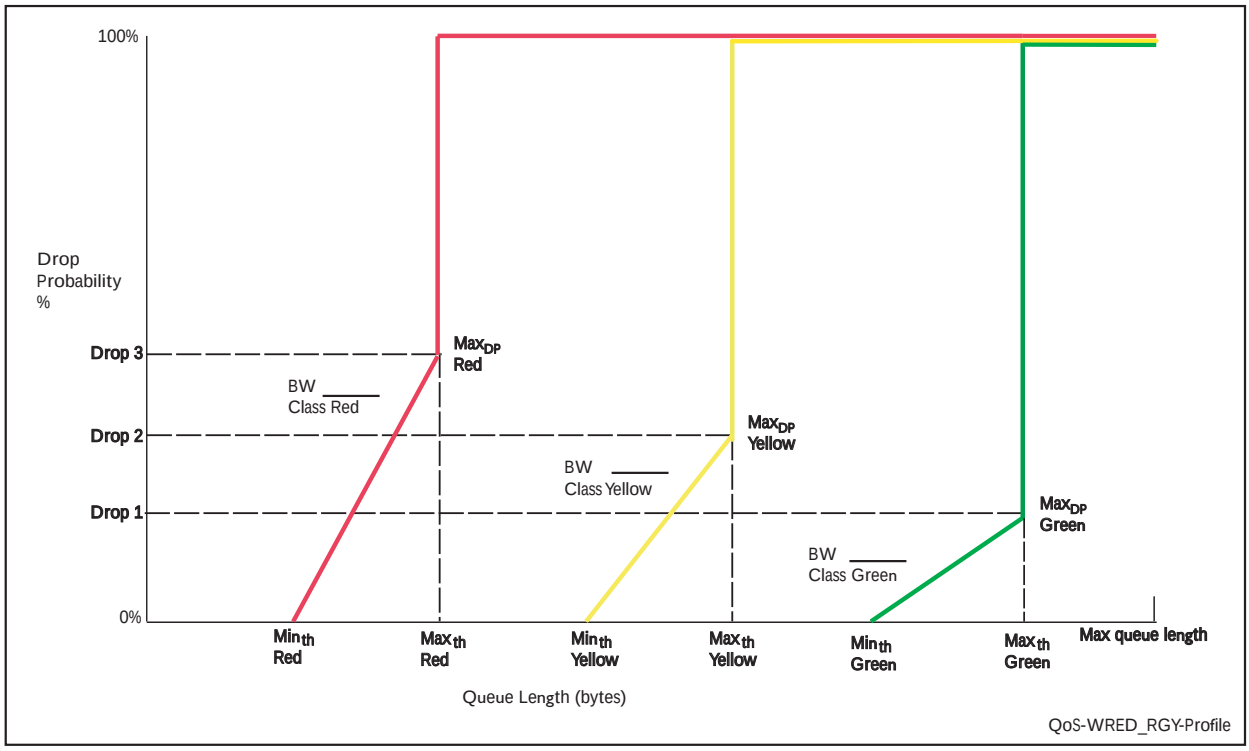
Each queue has an allocated buffer size, illustrated in the figure by the *MAX queue length on the graph's x axis. Traffic entering the queue can be marked either Green (most conformant), Yellow, or Red (least conformant). As the queue length increases it will first reach point* Min_{th} *Red* the minimum threshold for Red traffic. At this point the port begins to drop some of its red class traffic. If the current data flow continues and the queue continues to fill, traffic is dropped in increasing amounts. The vertical axis of the graph shows the probability of a packet being dropped.

1. The following equation is used to calculate the average queue length (Q_{ave}):

   $Q_{ave} = [(1 - 1/2^n) * Q_{ave}] + [1/2^n * (Current\ queue\ length)]$

   Where n = the averaging factor
   See the mls qos queue-set averaging-factor command on page 61.41.

Figure 60-12: Random Early Detect - Drop Profile



As the buffer further increases it will reach the point Max_{th}. At this point the drop probability is at the point Max_dp on the chart's vertical axis. From this point on, any further increase in queue size results in all packets in red traffic being dropped. This should increase the queue space for the remaining yellow and green traffic.

If the queue continues to fill, the above situation will then apply to the yellow and green traffic, as the queue size meets their own configurable thresholds Min_{th} yellow, Max_{th} yellow etc. Setting these thresholds is covered in "Configuring Tail Drop and Random Early Detection" on page 60.30.

Configuring Tail Drop and Random Early Detection

Note that this section does not apply to ports on the XEM-2XP

As previously mentioned the defaults for both drop methods can be seen from Figure 60-10 on page 60.26 and Figure 60-11 on page 60.27. These tables show the same output for both tail-drop and RED detection methods. However, when tail-drop is applied the values for Min_{th} and average queue length (Q_{ave}) are ignored, and the drop probability is either 0 (for a current queue size $<Max_{th}$) or 100% for a current queue size $>Max_{th}$).

The defaults shown are simply factory presets and are not intended to produce a functional configuration. The information in this section is to provide the basic guidelines required for you to set-up a tail-drop or RED detection method based on you own QoS standards.

Some Rules and Guidelines for the x.900 and SwitchBlade® x908 series switches.

- Each port on your switch will be a member of a single switch processor instance: All ports within a XEM are members of the same processor instance. On 24 port

switches, such as the x900-24 series, ports 1-12 and ports 13-24 belong to separate processors.

- Each port contains 8 egress queues; these share the total queue buffer space allocated for the port. The per port upper limit is:
  - 1.8 MB when configured for normal size frames
  - 8.25 MB when configured for Jumbo frames
- Each processor instance has the following buffer limits:
  - When the switch is configured for normal frames, 8.2 MB is shared between its ports. For a 12 port processor, the buffer limit = 0.68 MB_{avg} per port, and for a single port processor, such as a XEM, the buffer limit is 8.2 MB.
  - When the switch is configured for jumbo frames 32 MB is shared between its ports. For a 12 port processor, the buffer limit = 2.6 MB_{avg} per port.
    For a single port processor, such as a XEM, the buffer limit = 32 MB.

Note

For each queue-set, use the wrr-queue queue-limit command on page 61.88 to allocate the buffer size for each of a ports 8 egress queues (see note below), then select suitable threshold values for each of the classes Red, Yellow, and Green for each queue. See mls qos queue-set threshold command on page 61.45.

When setting the wrr-queue queue-limit command, we recommend setting the average queue length for a maximum queue ratio of 37% across all used queues on the particular port (i.e. 4.62% per queue when using 8 queues). This will provide 667 KB per port (83 KB per queue) when the switch is set for normal frame sizes; and 3.1 MB per port (388 KB per queue) when the switch is set to support Jumbo frames. You can then use these values to form the basis for setting the Maxth value for your Green traffic. Once you have set the Maxth Green you can work back from this point to choose appropriate values for your Red and Yellow traffic.

At this point you should be ready to apply your configurations using tail-drop. If you want to use RED you will need to take the following additional steps. Configuring RED for more than a marginal performance advantage over tail-drop, will require a good understanding of RED configuration principles and of your networks traffic profiles and service quality expectations. The following steps are intended to configure a basic RED system using some rule-of-thumb settings. You will probably want to fine tune these settings for real traffic profiles.

- Using the Drop Probability Table below, select an appropriate value for the maximum drop probability value for each of the colors. For TCP traffic we suggest using a drop probability of 3 or 4. For Green traffic using UDP we suggest using a value of 7, for reasons given in the earlier part of this section. See mls qos queue-set drop-probability command on page 61.43.

Table 60-9: Drop Probability Table

Drop Value	0	1	2	3	4	5	6	7
Drop Probability	100%	50%	25%	12.5%	6.25%	3.12%	1.56%	0.78%

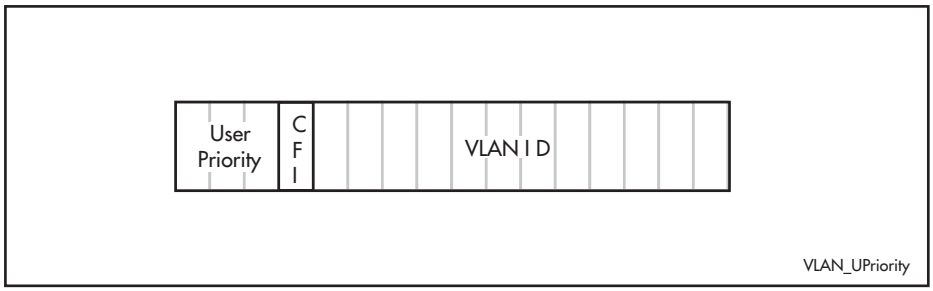
- For each queue-set, select suitable values for Min_{th} for each of the classes Red, Yellow, and Green for each queue within the set. We suggest that you start by setting each Min_{th} to be approximately half the value of the Max_{th} setting that you have already set for that particular color. See the mls qos queue-set threshold command on page 61.45.
- Select a value for the Queue Length Averaging Factor. We suggest you initially use the default of 9. See the mls qos queue-set averaging-factor command on page 61.41.

Egress Queue Mapping

On the switch you can use the match inner-vlan command on page 61.14 to select frames of a particular type. You can then assign these frames with a particular User Priority value then map them to one of eight egress queues. This facility enables you to accept frames that are already carrying meaningful priority information to be automatically assigned to an appropriate egress queue. For example, you could decide to send frames with a User Priority value of 7 to queue 3, and frames with a User Priority value of 2 to queue 7.

Frames entering a port at Layer 2 may be tagged or untagged. VLAN tagged frames contain 3 additional fields as shown in Figure 60-13 below. The User Priority field enables you to map incoming frames to any one of eight egress queues. This facility enables you can accept frames that are already carrying meaningful priority information to be automatically assigned to an appropriate egress queue. For example, you could decide to send frames with a User Priority value of 7 to queue 3, and frames with a User Priority value of 2 to queue 7.

Figure 60-13: User Priority Field



Mapping an Untagged frame to an Egress Queue

Frames entering a port with no VLAN tag and hence no User Priority Field, can be mapped to one of the eight Egress queue by using the mls qos queue command on page 61.38. For example, you could decide to send all untagged frames to a low priority egress queue such as queue 7.

Mapping an IEEE 802.1P value to an Egress Queue

Immediately after ingress, a VLAN-tagged Ethernet frame can be assigned to an appropriate egress queue, based on the priority value that is set within the frame's VLAN Tag Information Field (TIF). To create the mapping between the TIF and a ports egress queue see the mls qos map cos-queue to command on page 61.29.

Storm Protection

Storm protection uses QoS mechanisms to classify on traffic likely to cause a packet storm (broadcast and multicast). Unless you are running an enhanced storm protection feature such as Loop Protection, the per-port storm protection mechanism simply discards any traffic over the configured limit. However, with QoS storm protection, several actions are possible when a storm is detected:

- You can disable the port physically.
- You can disable the port logically.
- You can disable the port for a particular VLAN.

Before you can configure storm protection, you must first set the silicon profile to either extended or qoscounters. Silicon profiles are hardware-dependent - see the platform silicon-profile command on page 15.34. Storm protection is activated on a port after port state decisions have been made, and the port is in the STP forwarding state to forward frames and learn addresses.

When a storm is detected on a port, a message is automatically recorded in the log, and you can configure an SNMP trap to signal that a port has been disabled. When a storm is detected on a trunk or port group, the entire trunk or port group is disabled.

The following table explains the basic concepts involved with storm protection.

Concept	Description
Window	The frequency at which traffic is measured to determine whether storm protection should be activated.
Rate	The amount of traffic per second that must be exceeded before the switch takes the configured action.
Action	What the switch does when it detects a storm on a port.
Timeout	The length of time the port remains disabled after a port has been disabled due to a packet storm.

To set the action to take when triggered by QoS Storm Protection (QSP), use the storm-action command on page 61.78.

To set the time to re-enable the port once disabled by QSP, use the storm-downtime command on page 61.79.

To enable the policy-based storm protection QSP, use the storm-protection command on page 61.80.

QoS and the Switching Fabric

Ports on the x900 series switches belong to one of four switch processor instances: two on the base board and one on each expansion module. Switch instances exchange packets over a switching fabric. The switching fabric recognizes the priorities assigned to each packet and performs QoS queuing.

The switching fabric is different from the switch processor instance in that the switching fabric has four queues, whereas each switch port in a switch processor instance has eight egress queues. These two types of queues must be mapped to each other.

To specify the mapping of the 8 switch processor port queues to the 4 fabric queues, use the command: mls qos map fabric-queue command on page 61.30.

The integers *q0* to *q7* indicate the fabric queue that corresponds to an egress queue.

You can also configure the switching fabric to use different scheduling methods for each of the four fabric queues. This controls the way that fabric queues share the available bandwidth during congested times. See the mls qos map fabric-queue command on page 61.30.

To display information about settings for the switching fabric, use the command: show mls qos fabric-queue command on page 61.63.

Policy-Based Routing

Policy based routing provides a means to create multiple paths to the same destination. The specific path that any particular packet will take can be based on configurable network metrics such as priority, protocol, or VLAN membership. For example, policy based routing can implement policies to allow or deny paths based on the identity of user devices, application, or packet sizes.

Practical Example

The example shown makes use of policy based routing to achieve the following:

1. Ensure that traffic being sent between local VLANs is switched normally.

2. Selects a particular egress path for traffic destined for the wide are networks.

Configuration Overview

A large government building houses employees from three separate government departments: Heath, Welfare, and Employment. Each department has its own local subnet, and an associated VLAN; these are:

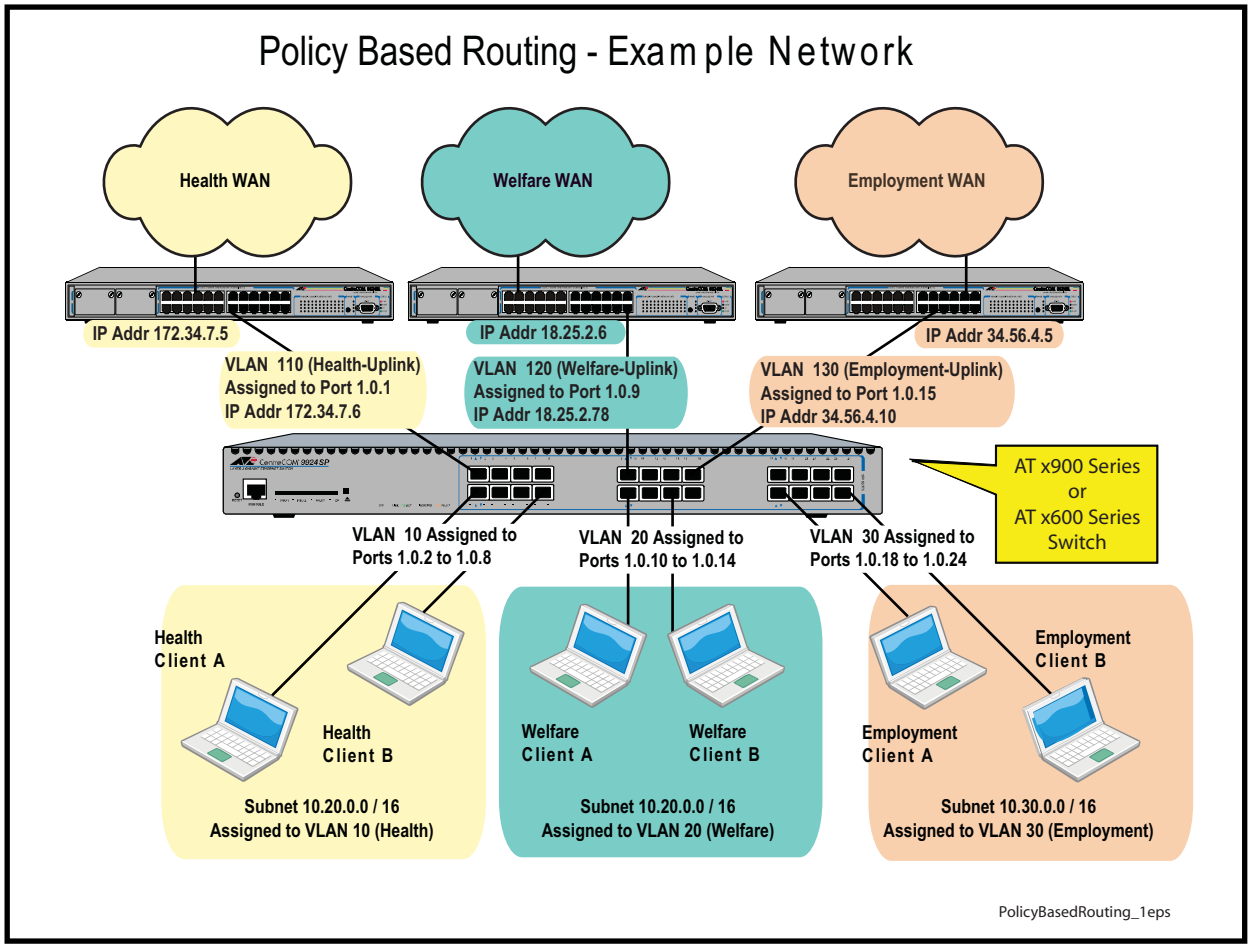
- 10.10.0.0/16 Health, VLAN 10
- 10.20.0.0/16 Welfare, VLAN 20
- 10.30.0.0/16 Employment, VLAN 30

Enquiries to each department are fed through a common Allied Telesis switch. The switch has 3 uplink ports, each of which (for simplicity) will be in a different VLAN and each will supply a connection to its relevant government department and to the Internet via each departments particular ISP (Internet Service Provider). These are:

- Port 1.0.1 Health Uplink, VLAN 110
- Port 1.0.5 Welfare Uplink, VLAN 120
- Port 1.0.21 Employment Uplink, VLAN 130

This configuration is illustrated in Figure 60-14:

Figure 60-14: Policy-Based Routing Example



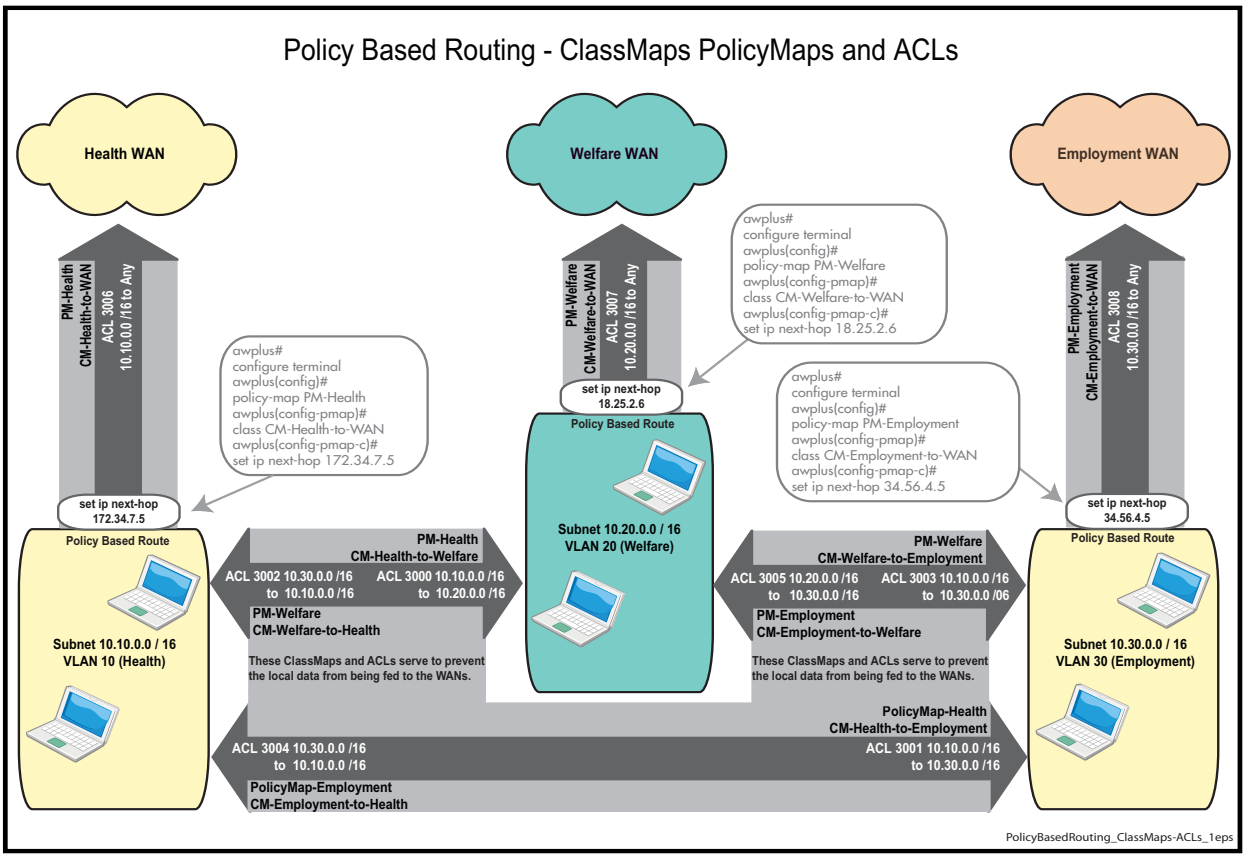
Configuration Steps

The following steps can be used to setup this example network. Since each step involves entering several instances of a command type, a single practical command entry is shown at the end of each step. The set of steps comprise the following:

1. Create VLANs on the switch.
2. Create access control lists (ACLs) that will match the data flows between local subnets.
3. Create ACLs that will match the data flows between local devices and other destinations.
4. Setup class-maps for each department and apply an access-list to each of the class maps.
5. Setup class-maps for each department's wide area connection and apply an access-list to each of these class maps.
6. Create the departmental policy-maps and associate them with their appropriate class-maps.
7. Apply these policy-maps to their appropriate ports.

These class-maps and ACLs are shown diagrammatically in Figure 60-15 below.

Figure 60-15: Policy Based Routing Example - ClassMaps and ACLs



Step 1: Create VLANs on the switch

- Create VLANs 10, 20, and 30
- Apply these VLANs to their appropriate local ports

Practical example: Create VLAN `10` and apply it to `port1.0.2-port1.0.8`.

```
awplus# configure terminal
awplus(config)# interface port port1.0.2-port1.0.8
awplus(config)# switchport mode access
awplus(config)# switchport access vlan 10
```

- Create VLANs 110, 120, and 130
- Apply these VLANs to their appropriate WAN ports

Practical example: Create VLAN `110` and apply it to `port1.0.1`.

```
awplus# configure terminal
awplus(config)# interface port port1.0.1
awplus(config)# switchport mode access
awplus(config)# switchport access vlan 110
```

Step 2: Create access control lists (ACLs) that will match the data flows between local user devices.

- access-list 3000 permit ip 10.10.0.0/16 10.20.0.0/16
  Matches for packets from the Health user devices to Welfare user devices.
- access-list 3001 permit ip 10.10.0.0/16 10.30.0.0/16
  Matches packets from the Health user devices to Employment user devices.
- access-list 3002 permit ip 10.20.0.0/16 10.10.0.0/16
  Matches packets from the Welfare user devices to Health user devices.
- access-list 3003 permit ip 10.20.0.0/16 10.30.0.0/16
  Matches packets from the Welfare user devices to Employment user devices.
- access-list 3004 permit ip 10.30.0.0/16 10.10.0.0/16
  Matches packets from the Employment user devices to Health user devices.
- access-list 3005 permit ip 10.30.0.0/16 10.20.0.0/16
  Matches packets from the Employment user devices to Welfare user devices.

Practical example: Create an ACL that matches packets from the Health user devices to Welfare user devices.

```
awplus# configure terminal
awplus(config)# access-list 3000 permit ip 10.10.0.0/16
10.20.0.0/16
```

Step 3: Create access control lists (ACLs) that will match the data flows between user devices and all other destinations.

- access-list 3006 permit ip 10.10.0.0/16 any
  Matches packets from Health user devices to all other destinations.
- access-list 3007 permit ip 10.20.0.0/16 any
  Matches packets from Welfare user devices all other destinations.
- access-list 3008 permit ip 10.30.0.0/16 any
  Matches packets from Employment user devices to all other destinations.

Practical example: Matches packets from the Health user devices to all other destinations.

```
awplus# configure terminal
awplus(config)# access-list 3006 permit ip 10.10.0.0/16 any
```

Step 4: Setup class-maps for each department and apply an access-list to each of the class maps.

- class-map CM-Health-to-Welfare
  Creates a class map called CM-Health-to-Welfare
- match access-group 3000
  Applies the access-list 3000 to the CM-Health-to-Welfare class-map, so that this class-map applies to all packets matching this ACL.
- class-map CM-Health-to-Employment
  Creates a class map called CM-Health-to-Employment.
- match access-group 3001
  Applies the access-list 3001 to the CM-Health-to-Employment class-map, so that this class-map applies to all packets matching this ACL.
- class-map CM-Welfare-to-Health
  Creates a class map called CM-Welfare-to-Health.
- match access-group 3002
  Applies the access-list 3002 to the CM-Welfare-to-Health class-map, so that this class-map applies to all packets matching this ACL.
- class-map CM-Welfare-to-Employment
  Creates a class map called CM-Welfare-to-Employment.
- match access-group 3003
  Applies the access-list 3003 to the CM-Welfare-to-Employment class-map, so that this class-map applies to all packets matching this ACL.
- class-map CM-Employment-to-Health
  Creates a class map called Employment-to-Health.
- match access-group 3004
  Applies the access-list 3004 to the CM-Employment-to-Health class-map, so that this class-map applies to all packets matching this ACL.
- class-map CM-Employment-to-Health
  Creates a class map called CM-Employment-to-Health.
- match access-group 3005
  Applies the access-list 3005 to the class-map CM-Employment-to-Health class-map, so that this class-map applies to all packets matching this ACL.

Practical example: Create the class-map Health-to-Welfare, then apply access list `3000` to it.

```
awplus# configure terminal
awplus(config)# class-map Health-to-Welfare
awplus(config-cmap)# match access-group 3000
```

Step 5: Setup class-maps for each department's wide area connection and apply an access-list to each of these class maps.

- class-map CM-Health-to-WAN
  Creates a class map called CM-Health-to-WAN.
- match access-group 3006
  Applies the access-list 3006 to the CM-Health-to-WAN class-map, so that this class-map applies to all packets matching this ACL.
- class-map CM-Welfare-to-WAN
  Creates a class map called Welfare-to-WAN
- match access-group 3007
  Applies the access-list 3007 to the CM-Welfare-to-WAN class-map, so that this class-map applies to all packets matching this ACL.
- class-map CM-Employment-to-WAN
  Creates a class map called Employment-to-WAN.
- match access-group 3008
  Applies the access-list 3008 to the CM-Employment-to-WAN class-map, so that this class-map applies to all packets matching this ACL.

Practical example: Create the class-map Health-to-Welfare, then apply access list `3006` to it.

```
awplus# configure terminal
awplus(config)# class-map CM-Health-to-WAN
awplus(config-cmap)# match access-group 3006
```

Step 6: Create the Departmental Policy-Maps and associate them with their appropriate Class-Maps.

- policy-map PM-Health
  Creates the policy-map called PM-Health
- class CM-Health-to-Welfare
- class CM-Health-to-Education
  Attaches the local Health class-maps to the PM-Health policy-map. Note that no action is applied to these two class maps. Packets that match either of these two class-maps will be forwarded across the local network using normal routing / forwarding procedures.
- class CM-Health-to-WAN
- set ip next-hop 172.34.7.5
  Attaches the CM-Health-to-WAN class-map to this policy-map, and gives it a policy-routing action.
- policy-map PM-Welfare
  Creates the policy-map called PM-Welfare
- class CM-Welfare-to-Health
- class CM-Welfare-to-Employment
  Attaches the local Welfare class-maps to the PM-Welfare policy-map. Note that no action is applied to these two class maps. Packets that match either of these two class-maps will be forwarded across the local network using normal routing / forwarding procedures.
- class CM-Welfare-to-WAN

- set ip next-hop 18.25.2.6
  Attaches the Welfare-to-WAN class-map to this policy-map, and gives it a policy-routing action.
- policy-map PM-Employment
  Creates the policy-map called PM- Employment
- class CM-Employment-to-Health
- class CM-Employment-to-Welfare
  Attaches the local Employment class-maps to the PM-Employment policy-map. Note that no action is applied to these two class maps. Packets that match either of these two class-maps will be forwarded across the local network using normal routing / forwarding procedures.
- class CM-Employment-to-WAN
- set ip next-hop 34.56.4.5
  Attaches the Employment-to-WAN class-map to this policy-map, and gives it a policy-routing action.

Practical example: Create the policy-map called PM-Employment and attach its appropriate classmaps.

```
awplus# configure terminal
awplus(config)# policy-map PM-Employment
awplus(config-pmap)# class CM-Employment-to-Health
awplus(config-pmap-c)# exit
awplus(config-pmap)# class CM-Employment-to-Welfare
awplus(config-pmap-c)# exit
awplus(config-pmap)# class CM-Employment-to-WAN
awplus(config-pmap-c)# set ip next-hop 34.56.4.5
```

Step 7: Apply these Policy Maps to appropriate ports.

- service-policy input Health-to-WAN
- service-policy input Welfare-to-WAN
- service-policy input Employment-to-WAN

Practical example: To apply a policy map named pm-employment to `port 1.0.18-port1.0.24`:

```
awplus# configure terminal
awplus(config)# interface port1.0.18-port1.0.24
awplus(config-if)# service-policy input pm-employment
```

Chapter 61: QoS Commands

Command List 61.3
class 61.3
class-map 61.4
clear mls qos interface policer-counters 61.5
default-action 61.6
description (QOS policy map) 61.7
egress-rate-limit 61.8
match access-group 61.9
match cos 61.10
match dscp 61.11
match inner-cos 61.12
match inner-tpid 61.13
match inner-vlan 61.14
match ip-precedence 61.15
match mac-type 61.16
match protocol 61.17

storm-downtime 61.79
storm-protection 61.80
storm-rate 61.81
storm-window 61.82
trust dscp 61.83
trust dscp (XEM-2XP) 61.84
wrr-queue disable queues 61.85
wrr-queue egress-rate-limit queues 61.86
wrr-queue group weight queues 61.87
wrr-queue queue-limit 61.88

Command List

This chapter provides an alphabetical reference for Quality of Service commands. For more information, see Chapter 60, Quality of Service (QoS) Introduction and Chapter 55, Access Control Lists Introduction.

class

Use this command to associate an existing class map to a policy or policy map (traffic classification), and to enter Policy Map Class Configuration mode to configure the class map.

Use the no variant of this command to delete an existing class-map.

For more information on class-maps and policy maps, see the following sections:"Class Maps" on page 60.7 and "Policy Maps" on page 60.10.

Note that if your class map does not exist, you can create it by using the class-map command.

Syntax

```
class {<name>|default}
no class <name>
```

Parameter	Description
<name>	Name of the (already existing) class map.
`default`	Specify the default class map.

Mode Policy Map Class Configuration

Example The following example creates the policy map `pmap1`(using the policy-map command), then associates this to an already existing class map named `cmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)#
```

Related Commands class-map
policy-map

class-map

Use this command to create a class map.

Use the no variant of this command to delete the named class map.

Syntax

```
class-map <name>
no class-map <name>
```

Parameter	Description
<name>	Name of the class map to be created.

Mode Global Configuration

Example This example creates a class-map called `cmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)#
```

clear mls qos interface policer-counters

Resets an interface's policer counters to zero. This can either be for a specific class-map or for all class-maps.

Before running this command you must first enable the QoS counter platform enhanced mode.

Syntax

```
clear mls qos interface <port> policer-counters
   [class-map <class-map>]
```

Parameter	Description
<port>	The port may be a switch port (e.g. `port1.0.4`), a static channel group (e.g. `sa3`), or a dynamic (LACP) channel group (e.g. `po4`).
`class-map`	Select a class-map.
<class-map>	Class-map name.

Mode Privileged Exec

Example To reset the policy counters to zero for all class maps for `port1.0.1`, use the command:

```
awplus# clear mls qos interface port1.0.1 policer-counters
```

Related Commands

platform silicon-profile
show mls qos interface policer-counters

default-action

Sets the action for the default class-map belonging to a particular policy-map. The action for a non-default class-map depends on the action of any ACL that is applied to the policy-map.

The default action can therefore be thought of as specifying the action that will be applied to any data that does not meet the criteria specified by the applied matching commands.

Use the no variant of this command to reset to the default action of 'permit'.

Syntax

```
default-action [permit|deny|send-to-cpu|copy-to-cpu|copy-to-mirror|
   send-to-mirror]

no default-action
```

Parameter	Description
`permit`	Packets to permit.
`deny`	Packets to deny.
`send-to-cpu`	Specify packets to send to the CPU.
`copy-to-cpu`	Specify packets to copy to the CPU.
`copy-to-mirror`	Specify packets to copy to the mirror port.
`send-to-mirror`	Specify packets to send to the mirror port.

Default The default is '`permit`'.

Mode Policy Map Configuration

Examples To set the action for the default class-map to `deny`, use the command:

```
awplus(config-pmap)# default-action deny
```

To set the action for the default class-map to `copy-to-mirror` for use with the mirror interface command, use the command:

```
awplus(config-pmap)# default-action copy-to-mirror
```

Related Commands mirror interface

description (QOS policy map)

Adds a textual description of the policy-map. This can be up to 80 characters long.

Use the no variant of this command to remove the current description from the policy-map.

Syntax

```
description <line>
no description
```

Parameter	Description
<line>	Up to 80 character long line description.

Mode Policy Map Configuration

Example To add the description, VOIP traffic, use the commands:

```
awplus(config-pmap)# description VOIP traffic
```

egress-rate-limit

Sets a limit on the amount of traffic that can be transmitted per second from this port.

Use the no variant of this command to disable the limiting of traffic egressing on the interface.

Syntax

```
egress-rate-limit <bandwidth>
no egress-rate-limit
```

Parameter	Description
<bandwidth>	Bandwidth <1-10000000 kbits per second> (usable units: k, m, g). The minimum is 651 Kb. The default unit is Kb (k), but Mb (m) or Gb (g) can also be specified. The command syntax is not case sensitive, so a value such as 20m or 20M will be taken to mean 20 megabits.

Mode Interface Configuration

Examples To enable egress rate limiting on a port, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# egress-rate-limit 500m
% Egress rate limit has been set to 500 Mb
```

To disable egress rate limiting on a port, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# no egress-rate-limit
```

match access-group

Use this command to define match criterion for a class map.

Syntax

```
match access-group {<hw-IP-ACL>|<hw-MAC-ACL>|<hw-named-ACL>}
no match access-group {<hw-IP-ACL>|<hw-MAC-ACL>|<hw-named-ACL>}
```

Parameter	Description
<hw-IP-ACL>	Specify a hardware IP ACL number in the range <3000-3699>.
<hw-MAC-ACL>	Specify a hardware MAC ACL number in the range <4000-4699>.
<hw-named-ACL>	Specify the hardware named ACL.

Mode Class Map Configuration

Usage First create an access-list that applies the appropriate permit, deny requirements etc. Then use the match access-group command to apply this access-list for matching to a class map. Note that this command will apply the access-list matching only to *incoming* data packets.

Examples To configure a class map named `cmap1` with one match criterion: `access-list 3001`, which allows IP traffic from any source to any destination, use the commands:

```
awplus# configure terminal
awplus(config)# access-list 3001 permit ip any any
awplus(config)# class-map cmap1
awplus(config-cmap)# match access-group 3001
```

To configure a class map named `cmap2` with one match criterion: `access-list 3001`, which allows MAC traffic from any source to any destination, use the commands:

```
awplus# configure terminal
awplus(config)# access-list 4001 permit any any
awplus(config)# class-map cmap2
awplus(config-cmap)# match access-group 4001
```

To configure a class map named `cmap3` with one match criterion: `access-list hw_acl`, which allows IP traffic from any source to any destination, use the commands:

```
awplus# configure terminal
awplus(config)# access-list hardware hw_acl
awplus(config-ip-hw-acl)# permit ip any any
awplus(config)# class-map cmap3
awplus(config-cmap)# match access-group hw_acl
```

Related Commands class-map

match cos

Sets the CoS for a class-map to match on.

Use the no variant of this command to remove CoS.

Syntax

```
match cos <0-7>
no match cos
```

Parameter	Description
<0-7>	Specify the CoS value.

Mode Class Map Configuration

Examples To set the class-map's CoS to 4, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match cos 4
```

To remove CoS from a class-map, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# no match cos
```

match dscp

Use this command to define the DSCP to match against incoming packets.

Use the no variant of this command to remove a previously defined DSCP.

Syntax

```
match dscp <0-63>
no match dscp
```

Parameter	Description
<0-63>	Specify DSCP value (only one value can be selected).

Mode Class Map Configuration

Usage Use the match dscp command to define the match criterion after creating a class map.

Examples To configure a class map named `cmap1` with criterion that matches IP DSCP 56, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match dscp 56
```

To remove a previously defined DSCP from a class map named cmap1, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# no match dscp
```

Related Commands class-map

match inner-cos

Sets the Inner CoS for a class-map to match on.

Use the no variant of this command to remove CoS.

Syntax

```
match inner-cos <0-7>
no match inner-cos
```

Parameter	Description
<0-7>	Specify the Inner CoS value.

Mode Class Map Configuration

Examples To set the class-map's inner-cos to 4, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match inner-cos 4
```

To remove CoS from the class-map, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# no match inner-cos
```

match inner-tpid

Sets the Inner Tag Protocol Identifier (TPID) for a class-map to match on.

Use the no variant of this command to remove the TPID for a class-map.

Syntax

```
match inner-tpid <tpid>
no match inner-tpid
```

Parameter	Description
<tpid>	Two byte hexadecimal number representing the TPID.

Mode Class Map Configuration

Examples To set the class-map's inner-tpid to 0x9100, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match inner-tpid 0x9100
```

To remove the class-map's inner-tpid, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# no match inner-tpid
```

match inner-vlan

Use this command to define the inner VLAN ID used as match criteria to classify a traffic class.

Use the no variant of this command to disable the VLAN ID used as match criteria.

Syntax

```
match inner-vlan <1-4094>
no match inner-vlan
```

Parameter	Description
<1-4094>	The VLAN number.

Mode Class Map Configuration

Usage This command is used in double-tagged networks to match on a VLAN ID belonging to the client network. For more information on VLAN double-tagged networks, see "VLAN Double Tagging (VLAN Stacking)" on page 16.5.

Examples To configure a class-map named `cmap1` to include traffic from inner VLAN 3, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match inner-vlan 3
```

To disable the configured VLAN ID as a match criteria for the class-map named `cmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# no match inner-vlan
```

match ip-precedence

Use this command to identify IP precedence values as match criteria.

Use the no variant of this command to remove IP precedence values from a class map.

Syntax

```
match ip-precedence <0-7>
no match ip-precedence
```

Parameter	Description
<0-7>	The precedence value to be matched.

Mode Class Map Configuration

Example To configure a class-map named `cmap1` to evaluate all IPv4 packets for a precedence value of `5`, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match ip-precedence 5
```

match mac-type

Use this command to set the MAC type for a class-map to match on.

Use no variant of this command to remove MAC type.

Syntax

```
match mac-type {l2bcast|l2mcast|l2ucast}
no match mac-type
```

Parameter	Description
l2bcast	Layer 2 Broadcast.
l2mcast	Layer 2 Multicast.
l2ucast	Layer 2 Unicast.

Mode Class Map Configuration

Examples To set the class-map's MAC type to Layer 2 multicast, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match mac-type l2mcast
```

To remove the class-map's MAC type, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# no match mac-type
```

match protocol

Sets the ethernet format and protocol for a class-map to match on. Select one Layer 2 eth-format “and” one Layer 3 protocol.

Use the no variant of this command to remove ethernet format and protocol from a class-map.

Syntax

```
match eth-format {<layer-two-format>} protocol {<layer-three-
    protocol>}

no match eth-format protocol
```

Parameter	Description
<layer-two-formats>	
802dot2-tagged	802.2 Tagged Packets (enter the parameter name).
802dot2-untagged	802.2 Untagged Packets (enter the parameter name).
ethii-tagged	EthII Tagged Packets (enter the parameter name).
ethii-untagged	EthII Untagged Packets (enter the parameter name).
netwareraw-tagged	Netware Raw Tagged Packets (enter the parameter name).
netwareraw-untagged	Netware Raw Untagged Packets (enter the parameter name).
snap-tagged	SNAP Tagged Packets (enter the parameter name).
snap-untagged	SNAP Untagged Packets (enter the parameter name).
<layer-three-protocols>	
<word>	A Valid Protocol Number in hexidecimal.
any	Note that the parameter “any” is only valid when used with the netwarerawtagged and netwarerawuntagged protocol options.
sna-path-control	Protocol Number 04 (enter the parameter name or its number).
proway-lan	Protocol Number 0E (enter the parameter name or its number).
eia-rs Protocol	Number 4E (enter the parameter name or its number).
proway Protocol	Number 8E (enter the parameter name or its number).
ipx-802dot2	Protocol Number E0 (enter the parameter name or its number).
netbeui	Protocol Number F0 (enter the parameter name or its number).
iso-clns-is	Protocol Number FE (enter the parameter name or its number).
xdot75-internet	Protocol Number 0801(enter the parameter name or its number).

Parameter(cont.)	Description(cont.)
nbs-internet	Protocol Number 0802 (enter the parameter name or its number).
ecma-internet	Protocol Number 0803 (enter the parameter name or its number).
chaosnet	Protocol Number 0804 (enter the parameter name or its number).
xdot25-level-3	Protocol Number 0805 (enter the parameter name or its number).
arp Protocol	Number 0806 (enter the parameter name or its number).
xns-compat	Protocol Number 0807 (enter the parameter name or its number).
banyan-systems	Protocol Number 0BAD (enter the parameter name or its number).
bbn-simnet	Protocol Number 5208 (enter the parameter name or its number).
dec-mop-dump-ld	Protocol Number 6001 (enter the parameter name or its number).
dec-mop-rem-cdons	Protocol Number 6002 (enter the parameter name or its number).
dec-decnet	Protocol Number 6003 (enter the parameter name or its number).
dec-lat	Protocol Number 6004 (enter the parameter name or its number).
dec-diagnostic	Protocol Number 6005 (enter the parameter name or its number).
dec-customer	Protocol Number 6006 (enter the parameter name or its number).
dec-lavc	Protocol Number 6007 (enter the parameter name or its number).
rarp	Protocol Number 8035 (enter the parameter name or its number).
dec-lanbridge	Protocol Number 8038 (enter the parameter name or its number).
dec-encryption	Protocol Number 803D (enter the parameter name or its number).
appletalk	Protocol Number 809B (enter the parameter name or its number).
ibm-sna	Protocol Number 80D5 (enter the parameter name or its number).
appletalk-aarp	Protocol Number 80F3 (enter the parameter name or its number).

Parameter(cont.)	Description(cont.)
snmp	Protocol Number 814Cv.
ethertalk-2	Protocol Number 809B (enter the parameter name or its number).
ethertalk-2-aarp	Protocol Number 80F3 (enter the parameter name or its number).
ipx-snap	Protocol Number 8137 (enter the parameter name or its number).
ipx-802dot3	Protocol Number FFFF (enter the parameter name or its number).
ip	Protocol Number 0800 (enter the parameter name or its number).
ipx	Protocol Number 8137 (enter the parameter name or its number).
ipv6	Protocol Number 86DD (enter the parameter name or its number).

Mode Class Map Configuration

Examples To remove the eth-format and protocol from the class-map, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# no match eth-format protocol
```

To set the class-map's eth-format to ethii-tagged and protocol to 0800 (IP), use the commands:

```
awplus# configure terminal
awplus(config)# class-map
awplus(config-cmap)# match eth-format ethii-tagged protocol
0800
```

or

```
awplus(config-cmap)# match eth-format ethii-tagged protocol ip
```

match tcp-flags

Sets one or more tcp flags (control bits) for a class-map to match on.

Use the no variant of this command to remove one or more tcp flags for a class-map to match on.

Syntax

```
match tcp-flags {[ack][fin][rst][syn][urg]}
no match tcp-flags {[ack][fin][rst][syn][urg]}
```

Parameter	Description
ack	Acknowledge.
fin	Finish.
rst	Reset.
syn	Synchronize.
urg	Urgent.

Mode Class Map Configuration

Examples To set the class-map's tcp flags to `ack` and `syn`, use the commands:

```
awplus# configure terminal
awplus(config)# class-map
awplus(config-cmap)# match tcp-flags ack syn
```

To remove the tcp-flags `ack` and `rst`, use the commands:

```
awplus# configure terminal
awplus(config)# class-map
awplus(config-cmap)# no match tcp-flags ack rst
```

match tpid

Sets the Tag Protocol Identifier (TPID) for a class map to match on.

Use the no variant of this command to remove the TPID for a class-map.

Syntax

```
match tpid <tpid>
no match tpid
```

Parameter	Description
<tpid>	Specify the Tag Protocol Identifier.

Mode Class Map Configuration

Examples To set the TPID of class map named `cmap1` to `0x9100`, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match tpid 0x9100
```

To remove the TPID set previously for class map named `cmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# no match tpid
```

match vlan

Use this command to define the VLAN ID used as match criteria to classify a traffic class.

Use the no variant of this command to disable the VLAN ID used as match criteria.

Syntax

```
match vlan <1-4094>
no match vlan
```

Parameter	Description
<1-4094>	The VLAN number.

Mode Class Map Configuration

Examples To configure a class-map named `cmap1` to include traffic from VLAN 3, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# match vlan 3
```

To disable the configured VLAN ID as a match criteria for the class-map named `cmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# class-map cmap1
awplus(config-cmap)# no match vlan
```

mls qos aggregate-police action

This command creates or reconfigures an aggregate-policer for a class-map.

The no variant of this command removes a previously configured exceed action.

Syntax For single rate metering:

```
mls qos aggregate-police <name> single-rate <CIR> <CBS> <EBS>
   action [drop-red|policed-dscp-transmit]
```

For twin rate metering:

```
mls qos aggregate-police <name> twin-rate <CIR> <CBS> <EIR> <PBS>
   action [drop-red|policed-dscp-transmit]
```

```
no mls qos aggregate-police <name>
```

Parameter	Description
<name>	Specify aggregate-policer name.
`single-rate`	Single rate meter (one rate and two burst sizes).
`twin-rate`	Twin rate meter (two rates and two burst sizes).
<CIR>	The Committed Information Rate. Specify an average traffic rate, 1-16000000 (kbps).
<CBS>	The amount by which the data is allowed to burst beyond the value set by the CIR. Specify a value from 0-16777216 (bytes).
<EIR>	Excess Information Rate. Specify an average traffic rate, 1-16000000 (kbps).
<EBS>	*For single-rate metering*, this is the amount by which the data is allowed to burst beyond the value set by the CIR.
<PBS>	*For twin-rate metering*, this is the amount by which the data is allowed to burst beyond the value set by the EIR. Specify a value from 1-16777216 (bytes).
`action`	Specify the action: either drop-red or policed-dscp-transmit.
`drop-red`	Drop the red packets.
`policed-dscp-transmit`	Change packet per policed-dscp map and send it.

Mode Global Configuration

Usage A policer can be used to meter the traffic classified by the class-map and as a result will be given one of three bandwidth classes. These are green (conforming), yellow (partially-conforming), and red (non-conforming).

Once you have created an aggregate policer, you can use the police-aggregate command on page 61.48 to assign it to one or more class-maps. This enables traffic classified by different characteristics to have accumulative application to the same policer. Another application of aggregate policers is to attach them to a single class-map but apply the class-maps to multiple ports (via it's policy-map). This enables the same traffic to have accumulative policed application over multiple ports.

A single-rate policer is based on three values. These are:

- average rate (or Committed Information Rate CIR)
- minimum burst (or Committed Burst Size CBS)
- maximum burst (or Excess Burst Size EBS)

Traffic is classed as green if the rate is less than the combined CIR plus CBS values. Traffic is classed as yellow if the data rate is between the CBS and the EBS. Traffic is classed as red if the rate exceeds the average rate and the EBS.

A dual-rate policer is based on four values. These are:

- average rate (or Committed Information Rate CIR)
- minimum burst (or Committed Burst Size CBS)
- maximum burst (or Excess Burst Size EBS)
- Excess Information Rate (EIR)

Traffic is classed as green if the rate is less than the CIR and CBS. Traffic is classed as yellow if the rate is between the CBS and the EBS. Traffic is classed as red if the rate exceeds the average rate and the EBS.

Using an action of drop-red will result in all packets classed as red being discarded.

When using an action of policed-dscp-transmit the packet will be remarked with the values configured in the policed-dscp map. The index into this map is determined by the DSCP in the packet. If a DSCP index is to be forced regardless of the packet DSCP the set dscp command can be used to achieve this. If no DSCP is present in the packet an index of 0 will be used.

Example To create a single rate meter measuring traffic of 10 Mbps that drops any traffic bursting over 30000 bytes, use the commands:

```
awplus# configure terminal
awplus(config)# mls qos aggregate-police ap1 single-rate 10000
                20000 30000 action drop-red
awplus(config)#
```

police-aggregate
show mls qos aggregate-policer
show mls qos maps policed-dscp

mls qos cos

This command assigns a CoS (Class of Service) user-priority value to untagged frames entering a specified interface. By default, all untagged frames are assigned a CoS value of 0.

Use the no variant of this command to return the interface to the default CoS setting for untagged frames entering the interface.

Syntax

```
mls qos cos <0-7>

no mls qos cos
```

Parameter	Description
<0-7>	The Class of Service, user-priority value.

Default By default, all untagged frames are assigned a CoS value of 0. Note that for tagged frames, the default behavior is not to alter the CoS value.

Mode Interface Configuration

Example To assign a CoS user priority value of 3 to all untagged packets entering ports 1.0.1 to 1.0.20, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1-port1.0.20
awplus(config-if)# mls qos cos 3
```

mls qos enable

Use this command to globally enable QoS on the switch or stack.

Use the no variant of this command to globally disable QoS and remove all QoS configuration. The no variant of this command removes all class-maps, policy-maps, policers, and queue-sets that have been created. Running the no mls qos command will therefore remove all pre-existing QoS configurations on the switch.

Mode Global Configuration

Syntax

```
mls qos enable
no mls qos
```

Example To enable QoS on the switch, use the commands:

```
awplus# configure terminal
awplus(config)# mls qos enable
```

mls qos fabric-queue

Configures the scheduling algorithm for one or more fabric queues. If the scheduler is weighted round robin (WRR), a weighting can also be specified. You must specify at least one queue when setting this command.

The no variant of this command resets the scheduling algorithm for one or more input fabric queues. Default is priority.

Syntax

```
mls qos fabric-queue {[0][1][2][3]}{priority|wrr [weight <1-30>]}
no mls qos fabric-queue [0][1][2][3]
```

Parameter	Description
`0, 1, 2, 3`	Fabric queues being configured.
`priority`	Applies strict priority queue servicing to the selected queues.
`wrr`	Applies weighted round robin queue servicing to the selected queues.
`weight`	The weight for weighted round robin selection. Queues will then be serviced in proportion to their applied weights. Default is 1.
<1-30>	The weight value.

Mode Global Configuration

Usage Queues can be serviced in either priority sequence or a weighted round-robin sequence. By default all queues are set to priority servicing.

Priority Sequencing

In this mode the queue with the highest number, i.e. queue 3 will be emptied first, then queues 2, 1 and 0. Note that the lower queues will only be serviced if there is no data waiting in the higher numbered queues.

Weighted Round Robin Sequencing

In this mode the weighting that you assign to each queue will determine how often it is serviced with respect to the other WRR queues. For example, if queue 0 is configured with a weight of 5 and queue 1 is configured with a weight of 1, then queue 0 will be serviced 5 times more than queue 1. Setting all weights to the same value will therefore apply an unweighted round selection method.

Mixed Sequencing

If you configure the queues with a mix of priority queueing and WRR, the priority queues will be completely emptied, before the any WRR queue is serviced.

Examples To set the scheduler for fabric queues `0` and `1` to WRR and both have a weight of `5`, use the command:

```
awplus# configure terminal
awplus(config)# mls qos fabric-queue 0 1 wrr weight 5
```

To reset the scheduling algorithm for fabric-queues `0` and `1`, use the command:

```
awplus# configure terminal
awplus(config)# no mls qos fabric-queue 0 1
```

Related Commands mls qos map fabric-queue
show mls qos fabric-queue
show mls qos maps fabric-queue

mls qos map cos-queue to

Used to set the default CoS to queue mapping. This is the default queue mapping for packets that do not get assigned a queue via any other QoS functionality.

Use the no variant of this command to reset the cos-queue map back to its default setting. The default mappings for this command are:

```
CoS Priority :      0 1 2 3 4 5 6 7
--------------------------------
CoS QUEUE:          2 0 1 3 4 5 6 7
```

For more information see, "Mapping CoS tags to traffic types" on page 60.12.

Syntax

```
mls qos map cos-queue <cos-priority> to <queue-number>
no mls qos map cos-queue
```

Parameter	Description
<cos-priority>	CoS priority value. Can take a value 0 to 7.
<queue-number>	Queue number. Can take a value 0 to 7.

Mode Global Configuration

Examples To set the cos-queue map back to its defaults, use the command:

```
awplus# configure terminal
awplus(config)# no mls qos map cos-queue
```

:To map CoS 2 to queue 3, use the command:

```
awplus# configure terminal
awplus(config)# mls qos map cos-queue 2 to 3
```

mls qos map fabric-queue

This command maps eight egress queues to four fabric queues. Note that when entering this command, you must supply a mapping for all eight egress queues.

Use the no variant of this command to reset the fabric queue map. This table maps eight egress queues to four fabric-queues. The default maps egress queues 0 and 1 to fabric queue 0, egress queues 2 and 3 to fabric queues 1, egress queues 4 and 5 to fabric queue 2 and egress queues 6 and 7 to fabric queue 3.

Syntax

```
mls qos map fabric-queue q0 q1 q2 q3 q4 q5 q6 q7

no mls qos map fabric-queue
```

Parameter	Description
q0	Egress queue 0 (Select a value 0 to 3 to map this egress queue to one of the four fabric queues q0-q4).
q1	Egress queue 1 (Select a value 0 to 3 to map this egress queue to one of the four fabric queues q0-q4).
q2	Egress queue 2 (Select a value 0 to 3 to map this egress queue the one of the four fabric queues q0-q4).
q3	Egress queue 3 (Select a value 0 to 3 to map this egress queue to one of the four fabric queues q0-q4).
q4	Egress queue 4 (Select a value 0 to 3 to map this egress queue to one of the four fabric queues q0-q4).
q5	Egress queue 5 (Select a value 0 to 3 to map this egress queue to one of the four fabric queues q0-q4).
q6	Egress queue 6 (elect a value 0 to 3 to map this egress queue to one of the four fabric queues q0-q4).
q7	Egress queue 7 (Select a value 0 to 3 to map this egress queue to one of the four fabric queues q0-q4).

Mode Global Configuration

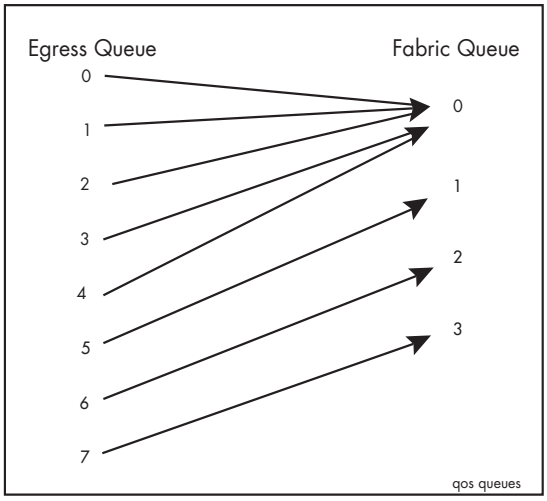
Examples This example maps egress queue 7 to fabric queue 3, egress queue 6 to fabric queue 2, egress queue 5 to fabric queue 1, and the rest of the egress queues to fabric queue 0, as shown in Figure 61-1 on page 61.31 use the command:

```
awplus# configure terminal
awplus(config)# mls qos map fabric-queue 0 0 0 0 0 1 2 3
```

The following table shows how the queue mapping operates in the above example:

Egress Queue	0	1	2	3	4	5	6	7
Fabric Queue Mapping	0	0	0	0	0	1	2	3

Figure 61-1: Egress Queue to Fabric Queue mapping:



To reset the fabric-queue map, use the command:

```
awplus# configure terminal
awplus(config)# no mls qos map fabric-queue
```

Related Commands

mls qos fabric-queue
show mls qos fabric-queue
show mls qos maps fabric-queue

mls qos map policed-dscp to

Configures the policed-dscp map. This is used when a policer is configured with an exceed action of 'policed-dscp-transmit'. Bandwidth-class is optional - if omitted, the changes will be applied to all bandwidth classes. At least one 'new' parameter must be specified.

Use the no variant of this command to reset the policed-dscp map to its default. This is used when a policer is configured with an exceed action of 'policed-dscp-transmit'. Specifying DSCP and bandwidth-class is optional. If no DSCP is specified then all DSCP entries will be reset to their defaults. If no bandwidth-class is specified then all bandwidth-class entries will be reset to their defaults.

Syntax

```
mls qos map policed-dscp <existing-dscp> [bandwidth-class {green|
   yellow|red}] to {[new-dscp <0-63>] [new-cos <0-7>]
   [new-queue <0-7>] [new-bandwidth-class {green|yellow|red}]}

no mls qos map policed-dscp [<new-dscp>] [bandwidth-class {green|
   yellow|red}]
```

Parameter	Description
<existing-dscp>	The value of the DSCP when it leaves the policer (meter) *<0-63>*.
bandwidth-class	Bandwidth Class.
green	Mark the packet as green.
yellow	Mark the packet as yellow.
red	Mark the packet as red.
to	Change the value to:
new-dscp	Modify Egress DSCP.
<0-63>	Egress DSCP value (marked down DSCP).
new-cos	Modify Egress CoS.
<0-7>	Egress CoS value (marked down CoS).
new-queue	Modify Egress Queue.
<0-7>	Egress Queue value (marked down Queue).
new-bandwidth-class	Modify Egress Bandwidth-class.
green	Egress Bandwidth-class green (marked down Bandwidth-class).
yellow	Egress Bandwidth-class yellow (marked down Bandwidth-class).
red	Egress Bandwidth-class red (marked down Bandwidth-class).
<new-dscp>	DSCP entry to reset.
bandwidth-class	bandwidth class to reset.
green	Green traffic.

Parameter(cont.)	Description(cont.)
yellow	Yellow traffic.
red	Red traffic.

Mode Global Configuration

Example To set the entry at DSCP 2 to remark the policed green traffic to a new DSCP of 2, a new CoS of 3, and new queue of 4 and a new bandwidth class of yellow, use the command:

```
awplus# configure terminal
awplus(config)# mls qos map policed-dscp 2 bandwidth-class
green to new-dscp 5 new-cos 3 new-queue 4 new-
bandwidth-class yellow
```

Related Commands
mls qos map policed-dscp to
police single-rate action
police twin-rate action
show mls qos maps policed-dscp

mls qos map premark-dscp to

The operation of this command varies by platform type. These platform types are:

- Generic platform - when applied to ports on the x900 chassis and non 2XP XEMs.
- XEM-2XP platform - when applied to ports on the XEM-2XP module.

Generic Platform

This command configures the premark-dscp map. It is used when traffic is classified by a class-map that has trust dscp configured. Based on a lookup DSCP, the map determines a new DSCP, COS, queue and bandwidth class for the traffic.

If the set dscp command has also been specified for that class-map, the set value is used for the lookup of the premark-dscp map. Otherwise the DSCP value in the packet is used for the lookup.

The no variant of this command resets the premark-dscp map to its defaults. If no DSCP is specified then all DSCP entries will be reset to their defaults.

Syntax

```
mls qos map premark-dscp <0-63> to {[new-dscp <0-63>]
   [new-cos <0-7>] [new-queue <0-7>] [new-bandwidth-class {green|
   yellow|red}]}

no mls qos map premark-dscp [<0-63>]
```

Parameter	Description
`premark-dscp <0-63>`	The DSCP value on ingress.
`new-dscp <0-63>`	The DSCP value that the packet will have on egress. If unspecified, this value will remain the DSCP ingress value.
`new-cos <0-7>`	The CoS value that the packet will have on egress. If unspecified, this value will be set to zero.
`new-queue <0-7>`	Modify Egress Queue.
`new-bandwidth-class`	Modify Egress Bandwidth-class. If unspecified, this value will be set to green.
`green`	Egress Bandwidth-class green (marked down Bandwidth-class).
`yellow`	Egress Bandwidth-class yellow (marked down Bandwidth-class).
`red`	Egress Bandwidth-class red (marked down Bandwidth-class).

Mode Global Configuration

Usage With the "trust dscp" on page 61.83 set, this command (mls qos map premark-dscp) enables you to remap any or all of the dscp, CoS, output queue, or bandwidth class values in one step, i.e. a single run of this command.

Example To set the entry for DSCP `1` to use a new DSCP of `2`, a new CoS of `3`, a new queue of `4` and a new bandwidth class of yellow, use the command:

```
awplus# configure terminal
awplus(config)# mls qos map premark-dscp 1 to new-dscp 2 new-
cos 3 new-queue 4 new-bandwidth-class yellow
```

XEM-2XP Platform

This command configures the premark-dscp map. It is used when traffic is classified by a policy-map that has trust dscp (XEM-2XP) configured. Based on a lookup DSCP, the map determines a new DSCP, COS, queue and bandwidth class for the traffic. The DSCP value in the packet is used for the lookup.

The no variant of this command resets the premark-dscp map to its defaults. If no DSCP is specified then all DSCP entries will be reset to their defaults.

Syntax

```
mls qos map premark-dscp <0-63> to {[new-dscp <0-63>]
   [new-cos <0-7>] [new-queue <0-7>] [new-bandwidth-class{green|
   yellow|red}]}

no mls qos map premark-dscp [<0-63>]
```

Parameter	Description
`premark-dscp <0-63>`	The DSCP value on ingress.
`new-dscp <0-63>`	The DSCP value that the packet will have on egress. If unspecified, this value will remain the DSCP ingress value.
`new-cos <0-7>`	The CoS value that the packet will have on egress. If unspecified, this value will retain its value on ingress.
`new-queue <0-7>`	Modify Egress Queue.
`new-bandwidth-class`	Modify Egress Bandwidth-class. If unspecified, this value will be set to green.
`green`	Egress Bandwidth-class green (marked down Bandwidth-class).
`yellow`	Egress Bandwidth-class yellow (marked down Bandwidth-class).
`red`	Egress Bandwidth-class red (marked down Bandwidth-class).

Mode Global Configuration

Usage With the trust dscp (XEM-2XP) command set, this command (mls qos map premark-dscp) enables you to make the following changes:

1. remap the DSCP (leaving the other settings unchanged)
2. remap any or all of CoS, output queue, or bandwidth class values (leaving the dscp unchanged)

Note If you attempt to remap both the dscp and another setting, only the dscp remap will take effect.

Example To set the entry for DSCP `1` to use a new DSCP of `2`, a new CoS of `3`, a new queue of `4` and a new bandwidth class of `yellow`, use the commands:

```
awplus# configure terminal
awplus(config)# mls qos map premark-dscp 1 to new-dscp 2
awplus(config)# mls qos map premark-dscp 2 to new-cos 3
awplus(config)# mls qos map premark-dscp 2 to new-queue 4
awplus(config)# mls qos map premark-dscp 2 to new-bandwidth-
class yellow
```

Generic and XEM-2XP Platforms

To reset the entry for DSCP `1` use the command:

```
awplus# configure terminal
awplus(config)# no mls qos map premark-dscp 1
```

Related Commands
mls qos map policed-dscp to
set dscp
show mls qos maps premark-dscp
trust dscp (XEM-2XP)

mls qos queue

Configures the default egress queue for any packet arriving on the specified interface. When no default queue is configured the cos-queue map is used to choose the queue for the packet.

Use the no variant of this command to turn off the use of a default queue on the interface.

Syntax

```
mls qos queue <0-7>
```

```
no mls qos queuebb
```

Parameter	Description
<0-7>	The particular queue number.

Mode Interface Configuration

Examples To set the default egress queue to 7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# mls qos queue 6
```

To turn off the default mls queue usage on port1.0.1 use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# no mls qos queue
```

Related Commands show mls qos interface

mls qos queue-set

Sets an interface to use the specified queue-set in either taildrop or random-detect mode.

When operating in taildrop mode only the maximum threshold parameters for each bandwidth-class are used from the queue-set. When the actual queue-length for any bandwidth-class exceeds this threshold the packets are discarded instead of being enqueued to the egress port.

When operating in random-detect mode all the parameters from the queue-set are used. The queue-length that is used in this mode is a calculated “average” queue length which can vary depending on what the averaging-factor has been configured to. This provides a more randomized discarding of packets during congestion and prevents TCP global flow synchronization. The down side of this is that more packets are dropped.

By default all ports are assigned to a queue-set created for each class of port (100 M, 1G or 10 G). All ports are also set to operate in taildrop mode. Also all traffic destined for the CPU will use queue-set 4.

Use the no variant of this command to reset a queue-set back to it's defaults. If one or more queues are specified then only those queue's will be reset. Otherwise, if no queue is specified the entire queue-set will be reset.

Syntax

```
mls qos queue-set <1-4> [random-detect|taildrop]
no mls qos queue-set <1-4> queues [0][1][2][3][4][5][6][7]
```

Parameter	Description
<1-4>	Queue-set ID.
`random-detect`	Apply this queue-set via Weighted Random Detect mode.
`taildrop`	Apply this queue-set via Taildrop mode.
`[0][1]...[7]`	Egress queues.

Mode Global Configuration and Interface Configuration

Usage This command is not applied to ports on the XEM-2XP module.

Examples To set `port1.0.1` to use queue-set `2` in random-detect mode, use the command:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# mls qos queue-set 2 random-detect
```

To reset queue-set `2` back to its defaults for queues 1-3, use the command:

```
awplus# configure terminal
awplus(config)# no mls qos queue-set 2 queues 1 2 3
```

Related Commands
mls qos queue-set averaging-factor
mls qos queue-set description
mls qos queue-set drop-probability

mls qos queue-set threshold
show mls qos interface
show mls qos queue-set

mls qos queue-set averaging-factor

Sets the averaging-factor for the specified queue-set and queue. This determines how quickly the average queue length follows the actual queue length. With a small averaging-factor, the average queue length follows the actual queue length quickly. As you increase the averaging-factor the average queue length will take longer to follow the actual queue length.

The queues parameter is optional and if not specified will default to setting the thresholds for all queues.

This parameter is only valid when a port is using this queue-set in random-detect mode.

Syntax

```
mls qos queue-set <1-4> queues {0 |1 |2 |3 |4 |5 |6 |7} averaging-
    factor <0-15>
```

Parameter	Description
<1-4>	Queue-set ID.
queues	List of queues to configure. Up to 8 queues (0-7) can be configured within a particular queue set.
averaging-factor	Configure queue length averaging factor.
<0-15>	Averaging factor value.

Mode Global Configuration

Usage This command is not applicable to ports on the XEM-2XP

Example To set the averaging-factor for queues 1-3 in queue-set `1` to be `4`, use the command:

```
awplus# configure terminal
awplus(config)# mls qos queue-set 1 queues 1 2 3 averaging-
                factor 4
```

Related Commands

mls qos queue-set
mls qos queue-set description
mls qos queue-set drop-probability
mls qos queue-set threshold
show mls qos interface
show mls qos queue-set

mls qos queue-set description

Sets the description for the specified queue-set. This is a textual string that can be up to 80 characters long.

Syntax `mls qos queue-set <1-4> description <line>`

Parameter	Description
<1-4>	Queue-set ID.
<line>	Description up to 80 characters.

Mode Global Configuration

Example To set the description for queue-set `1` to be "`Customized defaults`", use the commands:

```
awplus# configure terminal
awplus(config)# mls qos queue-set 1 description "Customized
defaults"
```

Related Commands
mls qos queue-set averaging-factor
mls qos queue-set drop-probability
mls qos queue-set threshold
show mls qos interface

mls qos queue-set drop-probability

Sets the drop probability for each bandwidth-class. This probability is the likelihood that a packet is dropped when the average queue length is between the minimum and maximum threshold for that bandwidth class. Once the average queue length is above the maximum threshold the probability jumps to 100%.

The queues parameter is optional and if not specified will default to setting the thresholds for all queues. This parameter is only valid when a port is using this queue-set in random-detect mode.

Syntax

```
mls qos queue-set <1-4> queues [0][1][2][3][4][5][6][7]
   drop-probability <0-15> <0-15> <0-15>
```

Parameter	Description
<1-4>	Queue-set ID.
`[0][2]...[7]`	List of queues to configure. Up to 8 queues (0-7) can be configured within a particular queue set.
`drop-probability`	Configure maximum drop probability for each bandwidth-class. See the following Drop Probability table.
<0-15>	Maximum drop-probability factor for green traffic.
<0-15>	Maximum drop-probability factor for yellow traffic.
<0-15>	Maximum drop-probability factor for red traffic.

Drop Probability

The drop probability is 100% for a setting of 0 and halves for each integer value increase. The following table shows probability values for drop values of 0 to 7. Default: 1.

Drop Value	0	1	2	3	4	5	6	7
Drop Probability	100%	50%	25%	12.5%	6.25%	3.125%	1.562%	0.781%

Mode Global Configuration

Usage This command is not applied to ports on the XEM-2XP module.

Example To set the drop-probability for queues 1-3 in queue-set `2` to be 50%, use the command:

```
awplus# configure terminal
awplus(config)# mls qos queue-set 2 queues 1 2 3
                drop-probability 1 1 1
```

The drop-probability parameter specifies the maximum drop-probability for packets when using the random-detect (RED) drop mode. This is the probability that a packet will be dropped when the computed average queue length reaches the Max threshold value setting for a specific traffic class within a specific queue.

The drop-probability is 100% for a drop value of 0, and halves with each increment. For example, a drop1 value of 4 gives a drop probability of 1/16, or 6.25%. The default is 1.

Related Commands

mls qos queue-set
mls qos queue-set averaging-factor
mls qos queue-set description
mls qos queue-set threshold
show mls qos interface
show mls qos queue-set

mls qos queue-set threshold

Sets the threshold parameters for the specified queue-set. There are six threshold parameters, which comprise a minimum and a maximum threshold value for each bandwidth-class.

The queues parameter is optional and if not specified will default to setting the thresholds for all queues. The minimum parameters are only valid when a port is using this queue-set in random-detect mode.

Note that only the maximum threshold setting will be applied when tail-drop mode is selected. However you must still enter a value for the minimum threshold; one method is to enter the same value for both maximum and minimum entries. See examples.

Syntax

```
mls qos queue-set <1-4> queues {0|1|2|3|4|5|6|7} threshold
   <1-16000000> <1-16000000> <1-16000000> <1-16000000> <1-16000000>
   <1-16000000>

no mls qos queue-set <1-4> queues {0|1|2|3|4|5|6|7}
```

Parameter	Description
<1-4>	Queue-set ID.
queues	List of queues to configure. Up to 8 queues (0-7) can be configured within a particular queue set.
threshold	Configure thresholds.
<1-16000000>	Minimum threshold for green traffic (Bytes).
<1-16000000>	Maximum threshold for green traffic (Bytes).
<1-16000000>	Minimum threshold for yellow traffic (Bytes).
<1-16000000>	Maximum threshold for yellow traffic (Bytes).
<1-16000000>	Minimum threshold for red traffic (Bytes).
<1-16000000>	Maximum threshold for red traffic (Bytes).

Mode Global Configuration

Usage This command is not applied to ports on the XEM-2XP module.

Examples Random Early Discard (RED) Example
To set the thresholds for queues 1-3 in queue-set 1 to a minimum or 1KB and a maximum of 2 KB, use the commands:

```
awplus# configure terminal
awplus(config)# mls qos queue-set 1 queues 1 2 3 threshold
1024 2048 1024 2048 1024 2048
```

Tail Drop Example

To set the thresholds for queue 2 in queue-set 1 to 1KB, use the commands:

```
awplus# configure terminal

awplus(config)# mls qos queue-set 1 queues 2 threshold 1024
                1024 1024 1024 1024 1024
```

no police

Disables any policer previously configured on the class-map.

Syntax `no police`

Mode Priority Map Class Configuration

Usage This command disables any policer previously configured on the class-map.

Example To disable policing on a class-map use the command:

```
awplus# configure terminal
awplus(config)# policymap name
awplus(config-pmap)# class classname
awplus(config-pmap-c)# no police
```

Related Commands
mls qos map policed-dscp to
police single-rate action
police twin-rate action
show mls qos maps policed-dscp

police-aggregate

Use this command to apply a previously created aggregate-policer to the class-map.

Use the no variant of this command to remove a previously created aggregate-policer from the class-map.

Syntax

```
police-aggregate <name>
no police-aggregate <name>
```

Parameter	Description
<name>	Specify a aggregate policer name.

Mode Policy Map Class Configuration

Usage This command enables you to apply an aggregate policer to a number of different class maps, and meter them as one group. Note that you cannot apply this command to any class map that already has a policer assigned by using the police single (or twin) rate exceed action command.

Examples To apply aggregate policer `ap1` to a class-map, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map name
awplus(config-pmap)# class classname
awplus(config-pmap-c)# police-aggregate ap1
```

To remove a previously created aggregate-policer from the class-map, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map name
awplus(config-pmap)# class classname
awplus(config-pmap-c)# no police-aggregate ap1
```

Related Commands
mls qos aggregate-police action
mls qos map premark-dscp to
mls qos map policed-dscp to
show mls qos aggregate-policer
show mls qos maps policed-dscp

police single-rate action

Configures a single-rate policer for a class-map.

Syntax

```
police single-rate <cir> <cbs> <ebs> action
   {drop-red|policed-dscp-transmit}|
```

Parameter	Description	
<cir>	Specify the Committed Information Rate (CIR) (1-16000000 kbps).	
<cbs>	Specify the Committed Burst Size (CBS) (0-16777216 bytes).	
<ebs>	Specify a Excess Burst Size (EBS) (0-16777216 bytes).	
`action`	Specify the action if rate is exceeded.	
	`drop-red`	Drop the red packets.
	`policed-dscp-transmit`	Modify packets using the *policed-dscp map*, then transmit. You can configure the remark policed-dscp map using the mls qos map policed-dscp to command on page 61.32.

Mode Policy Map Class Configuration

Usage A policer can be used to meter the traffic classified by the class-map and as a result will be given one of three bandwidth classes. These are green (conforming), yellow (partially-conforming), and red (non-conforming). A single-rate policer is based on three values. These are the average rate, minimum burst and maximum burst.

Color	Definition
`green`	The traffic rate is less than the average rate and minimum burst.
`yellow`	The traffic rate is between the minimum burst and the maximum burst.
`red`	The traffic rate exceeds the average rate and the maximum burst.

Using an action of drop-red means that any packets classed as red are discarded.

Note This command will not take effect when applied to a class map that attaches to a channel group whose ports span processor instances.

Example To configure a single rate meter measuring traffic of 10 Mbps that drops a sustained burst of traffic over this rate, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map name
awplus(config-pmap)# class classname
awplus(config-pmap-c)# police single-rate 10000 1875000 1875000
                        action drop-red
```

Related Commands

mls qos map policed-dscp to
no police
police twin-rate action
show mls qos maps policed-dscp

police twin-rate action

Configures a twin-rate policer for a class-map.

Syntax

```
police twin-rate <cir> <pir> <cbs> <pbs> action
   {drop-red|policed-dscp-transmit}|
```

Parameter	Description	
`<cir>`	Specify the Committed Information Rate (CIR) (1-16000000 kbps).	
`<pir>`	Specify the Peak Information Rate (PIR) (kbps).	
`<pbs>`	Specify the Peak Burst Size (PBS) (0-16777216 bytes).	
`action`	Specify the action if rate is exceeded.	
	`drop-red`	Drop the red packets.
	`policed-dscp-transmit`	Modify packets using the *policed-dscp map*, then transmit. You can configure the remark policed-dscp map using the mls qos map policed-dscp to command on page 61.32.

Mode Policy Map Class Configuration

Usage A policer can be used to meter the traffic classified by the class-map and as a result will be given one of three bandwidth classes. These are green (conforming), yellow (partially-conforming), and red (non-conforming).

A twin-rate policer is based on four values. These are the minimum rate, minimum burst size, maximum rate, and maximum burst size.

Bandwidth Class	Definition
`green`	The sum of the number of existing (buffered) bytes plus those arriving at the port per unit time, result in a value that is less than that set for the CBS.
`yellow`	The sum of the number of existing (buffered) bytes plus those arriving at the port per unit time, result in a value that is between those set for the CBS and the PBS.
`red`	The sum of the number of existing (buffered) bytes plus those arriving at the port per unit time, result in a value that exceeds that set for the PBS.

Using an action of drop-red means that any packets classed as red will be discarded.

When using an action of policed-dscp-transmit the packet will be remarked with the values configured in the policed-dscp map. The index into this map is determined by the DSCP in the packet. If a DSCP index is to be forced regardless of the packet DSCP the set dscp command can be used to achieve this. If no DSCP is present in the packet an index of 0 is used.

Example To configure a twin rate meter measuring a minimum rate of 10 Mbps and a maximum rate of 20 Mbps that uses the policed-dscp map to remark any non-conforming traffic, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map name
awplus(config-pmap)# class classname
awplus(config-pmap-c)# police twin-rate 10000 20000 1875000
3750000 action policed-dscp-transmit
```

Related Commands
mls qos map policed-dscp to
no police
police twin-rate action
show mls qos maps policed-dscp

policy-map

Use this command to create a policy map and to enter Policy Map Configuration mode to configure the specified policy map.

Use the no variant of this command to delete an existing policy map.

Syntax

```
policy-map <name>
no policy-map <name>
```

Parameter	Description
<name>	Name of the policy map.

Mode Global Configuration

Example To create a policy-map called `pmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)#
```

Related Commands class-map

priority-queue

Configures strict priority based scheduling on the specified egress queues. You must specify at least one queue.

Syntax `priority-queue {0}[1][2][3][4][5][6][7]`

Parameter	Description
`{0}[1]...[7]`	Specify queues to apply the scheduling rule in the range <0-7>. To apply priorities of `4`, `5` and `6` to queues `0`, `1` and `2` enter: `awplus(config-if)#priority-queue 4 5 6`

Mode Interface Configuration

Usage By default, the queues on all ports are set for priority queueing. You can change the queue emptying sequence to weighted round robin, by using the commands:mls qos fabric-queue command on page 61.27, or wrr-queue group weight queues command on page 61.87. You can then use the priority-queue command to reset the selected queues to priority queueing. Note that the emptying sequence for priority queueing is always highest queue number to lowest queue number.

For more information on queueing operation, see the chapter, Quality of Service (QoS) Introduction.

Example To apply priority based scheduling of `5`, `6` and `7` to egress queues 0, 1 and 2, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.1.12
awplus(config-if)# priority-queue 5 6 7
```

Related Commands
mls qos fabric-queue
show mls qos interface
show mls qos interface queue-counters
wrr-queue group weight queues

service-policy input

Use this command to apply a policy map to the input of an interface.

Use the no variant of this command to remove a policy map and interface association.

Syntax

```
service-policy input <policy-map>
no service-policy input <policy-map>
```

Parameter	Description
<policy-map>	Policy map name that the input will applied to.

Mode Interface Configuration

Usage This command can be applied to switch ports or static channel groups, but not to dynamic (LACP) channel groups.

Example To apply a policy map named `pmap1` to interface `port1.0.2`, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# service-policy input pmap1
```

set bandwidth-class

Use this command to set a bandwidth-class color to assign to classified traffic. The color represents the traffic's conformance to the policers allocated bandwidth. Green traffic is assumed to be conforming, yellow is semi-conforming, and red is non-conforming.

Use the no variant of this command to turn off a bandwidth-class color assigned to classified traffic.

Syntax

```
set bandwidth-class {green|yellow|red}
no set bandwidth-class {green|yellow|red}
```

Parameter	Description
green	Mark the packet as green.
yellow	Mark the packet as yellow.
red	Mark the packet as red.

Mode Policy Map Class Configuration

Examples To set the bandwidth class for all traffic classified by this class-map, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# set bandwidth-class green
```

Note that the class-map and policy-maps should already have been created by using the class-map command on page 61.4 and the policy-map command on page 61.53.

To turn off the setting of a packets in the green bandwidth-class, for the policy `pmap1` and the class `cmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# no set bandwidth-class green
```

Related Commands

class-map
set cos
set dscp
set queue
trust dscp
trust dscp (XEM-2XP)

set cos

Use this command to set a CoS value to assign to classified traffic.

Use the no variant of this command to turn off the CoS value assigned to classified traffic.

Note that this command is not valid with trust dscp (XEM-2XP).

Syntax

```
set cos <0-7>
no set cos
```

Parameter	Description
<0-7>	The new CoS value to be assigned.

Mode Policy Map Class Configuration

Examples To set the CoS value to 7 for all traffic classified by the selected class-map and policy-map, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# set cos 7
```

To turn off the above setting, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# no set cos
```

Related Commands
set bandwidth-class
set dscp
set queue
set dscp

set dscp

For a specific class-map and policy-map this command will assign or change the DSCP value within the packet. Note that where more than one class map has been assigned to a particular DSCP, the switch will apply the action of the class-map that was created first.

If trust dscp (XEM-2XP) has also been specified, the value determined by the set dscp command (i.e. that assigned to the class map and policy map) will be the value that is used by the lookup process in the premark-dscp mapping. The result of the lookup with then be assigned to the traffic.

The no variant of this command will negate the DSCP value specified with the set dscp command.

Syntax

```
set dscp <0-63>
no set dscp
```

Parameter	Description
<0-63>	The new DSCP value. A value between 0 and 63.

Mode Policy Map Class Configuration

Example To set a DSCP value of `35` to all traffic classified by a class-map of `cmap1` and a policy map of `pmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# set dscp 35
```

Related Commands

set bandwidth-class
set cos
set queue
trust dscp
trust dscp (XEM-2XP)

set ip next-hop (PBR)

Forwards traffic matching this class map to the specified nexthop.

When this command is set, all packets that match a selected class map will be forwarded to the specified nexthop.

The no variant of this command removes the next-hop address (in the context of its policy-map and class-map) from the configuration.

Syntax

```
set ip next-hop <ip-addr>
no set ip next-hop
```

Parameter	Description
<ip-addr>	The IP address of the next hop destination.

Mode Policy Map Class Configuration

Usage In typical deployments of policy-based routing, some traffic types require normal routing (i.e. via the routes in the IP routing table) while other traffic types require policy based routing.

Where the traffic to be policy routed is a subset of the traffic that is to be normally routed, then the configuration is reasonably simple. The policy-map will contain one or more classes that match the traffic to be policy routed, and will have their next-hop configured by this command - set ip next-hop (PBR). The remaining traffic will be conventionally routing routed according to the rules set for the default class - providing that this is not subject to the set ip next-hop (PBR).

The situation becomes a little more complex where the traffic requiring normal routing is a subset of the traffic to be policy-routed. In this situation the policy-map would need to contain one, or more, classes that match the requirement for normal routing, These classes would not be configured with a set ip next-hop (PBR) command. Then the remaining traffic classes that require normal routing would have the set ip next-hop (PBR) command applied to them. Note that this traffic could be just the default class, if ALL other traffic types were to be policy-routed.

Also note that the order in which the classes are configured in the policy-map is important; because traffic is matched against the classes in the order that they were assigned to the policy map.

Details of a practical example of such a policy-based routing is shown in "Policy-Based Routing" on page 60.35.

Example To forward a packet to a 192.168.1.1, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# set ip next-hop 192.168.1.1
```

Related Commands
set bandwidth-classs
set cos
set dscp
set queue

set queue

Use this command to set a queue value to assign to classified traffic. This will override the default queue as configured by mls qos queue command on page 61.38, but may be overridden by subsequent QoS mechanisms (such as remarking).

Use the no variant of this command to negate the queue value assigned to classified traffic by the set queue command.

This command is not valid if the trust dscp (XEM-2XP) command is set.

Syntax

```
set queue <0-7>
no set queue
```

Parameter	Description
<0-7>	Specify a new Queue value.

Mode Policy Map Class Configuration

Example To set the queue to value 7 for all traffic classified as cmap1 and pmap1, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# set queue 7
```

Related Commands

set bandwidth-class
set cos
set dscp
trust dscp
trust dscp (XEM-2XP)

show class-map

Use this command to display the QoS class maps to define the match criteria to classify traffic.

Syntax `show class-map <class-map name>`

Parameter	Description
<class-map name>	Name of the class map.

Mode User Exec and Privileged Exec

Example To display the QoS class maps to define the match criteria to classify traffic, use the command:

```
awplus# show class-map cmap1
```

Output Figure 61-2: Example output from the **show class-map** command

```
CLASS-MAP-NAME: cmap1
      Set IP DSCP: 56
      Match IP DSCP: 7
```

Related Commands class-map

show mls qos aggregate-policer

Displays all or a single aggregate-policer. If no name is specified, all aggregate policers will be displayed.

Syntax `show mls qos aggregate-policer [<name>]`

Parameter	Description
<name>	Aggregate policer name.

Mode User Exec and Privileged Exec

Example To display all aggregate-policers, use the command:

```
awplus# show mls qos aggregate-policer
```

Output Figure 61-3: Example output from the **show mls qos aggregate-policer** command

```
AGGREGATE-POLICER-NAME: ap1
Policer single-rate action drop-red:
average rate(1 kbps) minimum burst(2 B) maximum burst(3 B)
AGGREGATE-POLICER-NAME: ap2
Policer twin-rate action drop-red policed-dscp-tx:
minimum rate(1 kbps) maximum rate(2 kbps) minimum burst(3 B)
maximum burst(4 B)
```

Related Commands mls qos aggregate-police action
police-aggregate

show mls qos fabric-queue

Displays the scheduling algorithms for the fabric queues.

Syntax `show mls qos fabric-queue`

Mode User Exec and Privileged Exec

Example To display all scheduling algorithms for the fabric-queues, use the command:

```
awplus# show mls qos fabric-queue
```

Output Figure 61-4: Example output from the **show mls qos fabric-queue** command

```
fabric queue: 0
Scheduler: WRR
Weight: 5
Fabric Queue: 1
Scheduler: WRR
Weight: 1
Fabric Queue: 2
Scheduler: Priority
Fabric Queue: 3
Scheduler: Priority
```

Related Commands mls qos fabric-queue
show mls qos maps fabric-queue

show mls qos interface

Displays the current settings for the interface. This includes it's default CoS and queue, scheduling used for each queue, and any policies/maps that are attached.

Syntax `show mls qos interface [<port>]`

Parameter	Description
<port>	Switch port.

Mode User Exec and Privileged Exec

Example To display current CoS and queue settings for interface `port1.0.1`, use the command:

```
awplus# show mls qos interface port1.0.1
```

Output Figure 61-5: Example output from the **show mls qos interface** command

```
Default CoS:   7
    Default Queue: 7
    Number of egress queues: 8
    Queue Set: 1
    Egress Queue:         0
      Status:             Enabled
      Scheduler:          Strict Priority
      Queue Limit:        12%
      Egress Rate Limit: 0 Kb
    Egress Queue:         1
      Status:             Enabled
      Scheduler:          Strict Priority
      Queue Limit:        12%
      Egress Rate Limit: 0 Kb
    Egress Queue:         2
      Status:             Enabled
      Scheduler:          Strict Priority
      Queue Limit:        12%
      Egress Rate Limit: 0 Kb
    Egress Queue:         3
      Status:             Enabled
      Scheduler:          Wrr Group 2
      Weight:             10
      Queue Limit:        12%
      Egress Rate Limit: 0 Kb
    Egress Queue:         4
      Status:             Enabled
      Scheduler:          Wrr Group 1
      Weight:             10
      Queue Limit:        12%
      Egress Rate Limit: 0 Kb
    Egress Queue:         5
      Status:             Enabled
      Scheduler:          Strict Priority
      Queue Limit:        12%
      Egress Rate Limit: 0 Kb
    Egress Queue:         6
      Status:             Enabled
      Scheduler:          Strict Priority
      Queue Limit:        12%
      Egress Rate Limit: 0 Kb
    Egress Queue:         7
      Status:             Enabled
      Scheduler:          Strict Priority
      Queue Limit:        12%
      Egress Rate Limit: 0 Kb
```

Table 61-1: Parameters in the output of the **show mls qos interface** command

Parameter	Description
`Default CoS`	The default CoS priority that will be applied to all packets arriving on this interface.
`Default Queue`	The default queue that will be applied to all packets arriving on this interface.
`Number of egress queues`	The total number of egress queues available on this interface.
`Queue Set`	Drop queue set that has been applied to the port. This could either be operating in threshold or random-detect mode.
`Egress Queue X`	Number of this egress queue.
`Status`	Queue can either be enabled or disabled.
`Scheduler`	The scheduling mode being used for servicing the transmission of packets on this port.
`Queue Limit`	The percentage of the ports buffers that have been allocated to this queue.
`Egress Rate Limit`	The amount of traffic that can be transmitted via this queue per second. 0 Kb means there is currently no rate-limiting enabled.

Related Commands

mls qos queue
wrr-queue group weight queues
wrr-queue queue-limit

show mls qos interface policer-counters

Display an interface's policer counters. This can either be for a specific class-map or for all class-maps attached to the interface. If no class-map is specified all class-map policer counters attached to the interface will be displayed.

These are the counters based on metering performed on the specified class-map. Therefore, the 'Dropped packets' counter is the number of bytes dropped due to metering. This is different from the packets dropped via a 'deny' action in the ACL.

You must enable the QoS counter platform enhanced mode before running this command.

Syntax

```
show mls qos interface <port> policer-counters
   [class-map <class-map>]
```

Parameter	Description
<port>	Switch port.
`class-map`	Select a class-map.
<class-map>	Class-map name.

Mode User Exec and Privileged Exec

Example To show the counters for all class-maps attached to `port1.1.1`, use the command:

```
awplus# show mls qos interface port1.1.1 policer-counters
```

Output Figure 61-6: Example output from the **show mls qos interface policer-counters** command

```
Interface:           port1.1.1
   Class-map:         cmap1
     Aggregate Bytes: 128
     Green Bytes:     128
     Yellow Bytes:    0
     Red Bytes:       0
     Dropped Bytes:   0
```

Related Commands

mls qos queue
wrr-queue group weight queues
wrr-queue queue-limit

show mls qos interface queue-counters

Display an interface's egress queue counters. This can either be for a specific queue or for all queues on the interface. If no queue is specified all queue counters on the interface will be displayed.

The counters show the number of frames currently in the queue and the maximum number of frames allowed in the queue, for individual egress queues and the port's queue (which will be a sum of all eight egress queues).

Syntax

```
show mls qos interface <port> queue-counters queue [<0-7>]
```

Parameter	Description
<port>	Switch port.
<0-7>	Queue.

Mode User Exec and Privileged Exec

Usage The output of this command is now device specific. Specific output applies to switch ports on the XEM-2XP module, generic output applies to all other switch ports.

On the XEM-2XP, the maximum value of 219 represents (73+73+73) frames, where the value 73 (219 divided by 3) is the drop precedence, red, green, and yellow. It is therefore possible that for unmetered traffic (where all traffic is treated as being green) the queue length of 73 frames could be exceeded. Note also that the figure of 219 shown in the example is derived from the settings made in the wrr-queue queue-limit command on page 61.88 command.

Example Generic Port To show the counters for all queues on `port1.0.1`, use the command:

```
awplus# show mls qos interface port1.0.1 queue-counters
```

Output Generic Ports Figure 61-7: Example output from the **show mls qos interface queue-counters** command

```
Interface port1.0.1 Queue Counters:
   Port queue length         0 (maximum 896)
   Egress Queue length:
     Queue 0                 0 (maximum 112)
     Queue 1                 0 (maximum 112)
     Queue 2                 0 (maximum 112)
     Queue 3                 0 (maximum 112)
     Queue 4                 0 (maximum 112)
     Queue 5                 0 (maximum 112)
     Queue 6                 0 (maximum 112)
     Queue 7                 0 (maximum 112)
```

Output XEM-2XP Ports

Figure 61-8: Example output from the **show mls qos interface queue-counters** command

```
Interface port1.1.1 Queue Counters:
   Port queue length          0 (maximum 600)
   Egress Queue length:
     Queue 0                  0 (maximum 219)
     Queue 1                  0 (maximum 219)
     Queue 2                  0 (maximum 219)
     Queue 3                  0 (maximum 219)
     Queue 4                  0 (maximum 219)
     Queue 5                  0 (maximum 219)
     Queue 6                  0 (maximum 219)
     Queue 7                  0 (maximum 219)
```

Table 61-2: Parameters in the output of the **show mls qos interface queue-counters** command

Parameter	Description
`Interface`	Port we are showing the counters for.
`Port queue length`	Number of frames in the port's queue. This will be the sum of all egress queues on the port.
`Egress Queue length`	Number of frames in a specific egress queue, subject to the specific operation on the XEM-2XP module - see Usage Section.

Related Commands

wrr-queue queue-limit

show mls qos interface storm-status

Show the current configuration and status of the QoS Storm Protection (QSP) on the given port.

Syntax `show mls qos interface <port> storm-status`

Parameter	Description
<port>	Switch port.

Mode User Exec and Privileged Exec

Example To see the QSP status on `port1.0.1`, use command:

```
awplus# show mls qos interface port1.0.1 storm-status
```

Output Figure 61-9: Example output from the **show mls qos interface storm-status** command

```
Interface:            port1.0.1
Storm-Protection:     Enabled
Port-status:          Enabled
Storm Action:         vlandisable
Storm Window:         5000 ms
Storm Downtime:       0 s
Timeout Remaining:    0 s
Last read data-rate:  0 kbps
Storm Rate:           1000 kbps
```

Related Commands

show mls qos maps cos-queue

Show the current configuration of the cos-queue map.

Syntax `show mls qos maps cos-queue`

Mode User Exec and Privileged Exec

Example To display the current configuration of the cos-queue map, use the command:

```
awplus# show mls qos maps cos-queue
```

Output Figure 61-10: Example output from the **show mls qos maps cos-queue** command

```
COS-TO-QUEUE-MAP:
      COS :            0 1 2 3 4 5 6 7
      --------------------------------
      QUEUE:           0 7 1 3 4 5 6 7
```

Related Commands mls qos map cos-queue to

show mls qos maps fabric-queue

Displays the fabric queue map, which is a table mapping eight egress queues to four input fabric queues.

Syntax `show mls qos maps fabric-queue`

Mode User Exec and Privileged Exec

Example To display the `fabric-queue` map, use the command:

```
awplus# show mls qos maps fabric-queue
```

Output Figure 61-11: Example output from the **show mls qos maps fabric-queue** command

```
Egress Queue    Fabric Queue
    ----------------------
    0                0
    1                0
    2                1
    3                1
    4                2
    5                2
    6                3
    7                3
```

Output Parameter	Meaning
`Egress Queue`	Egress queue indexing the table
`Fabric Queue`	Resulting fabric queue for the egress queue lookup.

Related Commands
mls qos fabric-queue
mls qos map fabric-queue
show mls qos fabric-queue

show mls qos maps policed-dscp

Displays the policed-dscp map. This is used when a policer is configured with an exceed action of 'policed-dscp-transmit'.

Syntax `show mls qos maps policed-dscp [<0-63>]`

Parameter	Description
<0-63>	DSCP table entry.

Mode User Exec and Privileged Exec

Example To display the policed-dscp map for DSCP `1`, use the command:

```
awplus# show mls qos maps policed-dscp 1
```

Output Figure 61-12: Example output from the **show mls qos maps policed-dscp** command

```
POLICED-DSCP-MAP:
DSCP 1
Bandwidth Class Green Yellow Red
-------------------------------------------------
New DSCP 1 1 1
New CoS 0 0 0
New Queue 0 0 0
New Bandwidth Class green yellow red
```

Related Commands
mls qos map premark-dscp to
no police
police single-rate action
police twin-rate action

show mls qos maps premark-dscp

Displays the premark-dscp map. This map is used when the trust dscp (XEM-2XP) command has been specified for a policymap's class-map to replace the DSCP, CoS, queue, and bandwidth class of a packet matching the class-map based on a lookup DSCP value.

If the set dscp command has also been specified for that class-map, the set value is used for the lookup of the premark-dscp map. Otherwise the DSCP value in the packet is used for the lookup.

Syntax

```
show mls qos maps premark-dscp [<0-63>]
```

Parameter	Description
<0-63>	DSCP table entry.

Mode User Exec and Privileged Exec

Example To display the premark-dscp map for DSCP 1, use the command:

```
awplus# show mls qos maps premark-dscp 1
```

Output Figure 61-13: Example output from the **show mls qos maps premark-dscp** command

```
PREMARK-DSCP-MAP:

    DSCP 1
    Bandwidth Class         Green    Yellow   Red
    ------------------------------------------------
    New DSCP                1        -        -
    New CoS                 0        -        -
    New Queue               0        -        -
    New Bandwidth Class     green    -        -
```

Related Commands

mls qos map premark-dscp to

show mls qos queue-set

Displays the specified queue-set and its parameters. If no queue-set is specified then all queue sets will be displayed.

Syntax `show mls qos queue-set [<1-4>]`

Parameter	Description
<1-4>	Queue Set ID.

Mode User Exec and Privileged Exec

Usage This show output is invalid for ports on the XEM-2XP module.

Example To display `queue-set 1`, use the command:

```
awplus# show mls qos queue-set 1
```

Output Figure 61-14: Example output from the **show mls qos queue-set** command

```
Queue Set 1:
  Description: 1G Defaults

                BandwidthClass   Min           Max           Drop

    Queue 5: 9
    Queue 6: 9
    Queue 7: 9
```

Table 61-3: Parameters in the output of the **show mls qos queue-set** command

Parameter	Description
`Queue Set`	Queue-set number.
`Description`	Textual description for this queue-set.
`Queue X`	Parameter set for egress queue X.
`BandwidthClass`	Parameter set per-bandwidth-class per-queue.
`Min`	The amount of traffic required in the queue before packets start getting dropped.
`Max`	The amount of traffic required in the queue before all packets are dropped.
`Drop Probability`	The probability that a packet is dropped when the queue length is between the minimum and maximum for the bandwidth-class.
`Averaging Factor`	Determines how quickly the average queue length follows the actual queue length. A small averaging factor will cause the average to follow the actual more quickly and visa versa for a large averaging factor.

Related Commands

show mls qos interface
show mls qos queue-set

show policy-map

Displays the policy-maps configured on the switch. The output also shows whether or not they are connected to a port (attached / detached) and shows their associated class-maps.

Syntax `show policy-map [<name>]`

Parameter	Description
<name>	The name of a specific policy map.

Mode User Exec and Privileged Exec

Example To display a listing of the policy-maps configured on the switch, use the command:

```
awplus# show policy-map
```

Output Figure 61-15: Example output from the **show policy-map** command

```
POLICY-MAP-NAME: general-traffic
  State: attached
    Default class-map action: permit
    CLASS-MAP-NAME: default
    CLASS-MAP-NAME: database-traffic
```

Related Commands no police
service-policy input

storm-action

Sets the action to take when triggered by QoS Storm Protection (QSP). There are three available options:

- portdisable will disable the port in software.
- vlandisable will disable the port from the VLAN matched by the class-map in class-map.
- linkdown will physically bring the port down. The vlandisable requires the match vlan class-map to be present in the class-map.

The no variant of this command will negate the action set by the storm-action command.

Syntax

```
storm-action {portdisable|vlandisable|linkdown}
no storm-action
```

Parameter	Description
portdisable	Disable the port in software.
vlandisable	Disable the VLAN.
linkdown	Shutdown the port physically.

Mode Policy Map Class Configuration

Examples To apply the storm protection of `vlandisable` to the policy map named `pmap2`, and the class-map named `cmap1`, use the following commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap2
awplus(config-pmap)# class cmap1
awplus(config-pmap-c# storm-action vlandisable
```

To negate the storm protection set on the policy map named `pmap2`, and the class-map named `cmap1`, use the following commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap2
awplus(config-pmap)# class cmap1
awplus(config-pmap-c# no storm-action
```

Related Commands
storm-downtime
storm-protection
storm-rate
storm-window

storm-downtime

Sets the time to re-enable the port once disabled by QoS Storm Protection (QSP). The time is given in seconds, from a minimum of one second to maximum of 86400 seconds (i.e. one day).

The no variant of this command resets the time to the default value of 10 seconds.

Syntax

```
storm-downtime <1-86400>
no storm-downtime
```

Parameter	Description
<1-86400>	Seconds.

Default 10 seconds

Mode Policy Map Class Configuration

Examples To re-enable the port in 1 minute, use the following commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap2
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# storm-downtime 60
```

To re-set the port to the default (10 seconds), use the following commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap2
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# no storm-downtime
```

Related Commands

storm-action
storm-protection
storm-rate
storm-window

storm-protection

Use this command to enable the policy-based storm protection (such as QSP - QoS Storm Protection). Storm protection is activated on a port after port state decisions have been made.

The no variant of this command disables Policy Based Storm Protection.

Syntax

```
storm-protection
no storm-protection
```

Default By default, storm protection is disabled.

Mode Policy Map Class Configuration

Usage Before you can configure storm protection, you must first set the silicon profile to either extended or qoscounters. Silicon profiles are hardware-dependent—see the platform silicon-profile command on page 15.34.

Examples To enable QSP on `cmap2` in `pmap2`, use the following commands:

```
awplus# policy-map pmap2
awplus(config-pmap)# class cmap2
awplus(config-pmap-c)# storm-protection
```

To disable QSP on `cmap2` in `pmap2`, use the following commands:

```
awplus# policy-map pmap2
awplus(config-pmap)# class cmap2
awplus(config-pmap-c)# no storm-protection
```

Related Commands

platform silicon-profile
storm-action
storm-downtime
storm-rate
storm-window

storm-rate

Sets the data rate that triggers the storm-action. The rate is in kbps and the range is from 1kbps to 10Gbps.

Note that this setting is made in conjunction with the storm window command.

Use the no variant of this command to negate the storm-rate command.

Syntax

```
storm-rate <1-10000000>
no storm-rate
```

Parameter	Description
<1-10000000>	The range of the storm-rate.

Default No default

Mode Policy Map Class Configuration

Usage This setting is made in conjunction with the storm-window command on page 61.82.

Examples To the limit to 1Mbps, use the following commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap2
awplus(config-pmap)# class cmap2
awplus(config-pmap-c)# storm-rate 1000
```

To negate the limit set previously, use the following commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap2
awplus(config-pmap)# class cmap2
awplus(config-pmap-c)# storm-rate 1000
```

Related Commands

storm-action
storm-downtime
storm-protection
storm-window

storm-window

Sets the window size of QoS Storm Protection (QSP). This sets the time to poll the data-rate every given milliseconds. Minimum window size of 100 ms and the maximum is 60 sec.

Use the no variant of this command to negate the storm-window command.

Syntax

```
storm-window <100-60000>
no storm-window
```

Parameter	Description
<100-60000>	The window size, measured in milliseconds.

Default No default

Mode Policy Map Class Configuration

Usage This command should be set in conjunction with the storm-rate command on page 61.81.

Examples To set the QSP window size to `5000` ms, use the following commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap2
awplus(config-pmap)# class cmap2
awplus(config-pmap-c)# storm-window 5000
```

To negate the QSP window size set previously, use the following commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap2
awplus(config-pmap)# class cmap2
awplus(config-pmap-c)# storm-window 5000
```

storm-rate

trust dscp

On switch ports other than the XEM-2XP, this command enables the premark-dscp map to replace the bandwidth-class, cos, dscp, and queue of classified traffic based on a lookup DSCP value.

With the no variant of this command, no premark-dscp mapping function will be applied for the selected class-map. QoS components of the packet existing either at ingress, or applied by the class-map, will pass unchanged.

Syntax

```
trust dscp
no trust
```

Mode Policy Map Class Configuration

Usage If the set dscp command has also been specified for the class-map, the set value is used for the lookup of the premark-dscp map. Otherwise the DSCP value in the packet is used for the lookup.

Note that the set bandwidth-class, set cos and set queue are not valid with trust dscp.

Examples To enable the premark-dscp map lookup for policy-map `pmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# trust dscp
```

To disable the premark-dscp map lookup for policy-map `pmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap
awplus(config-pmap)# class cmap1
awplus(config-pmap-c)# no trust
```

Related Commands
mls qos map premark-dscp to
set bandwidth-class
set cos
set dscp
set queue
trust dscp (XEM-2XP)

trust dscp (XEM-2XP)

On the XEM-2XP module, use this command to enable the premark-dscp map to replace the bandwidth-class, cos, dscp, and queue of classified traffic within a policy-map based on a lookup DSCP value.

With the no variant of this command, no premark-dscp mapping function will be applied for the selected policy-map. QoS components of the packet existing at ingress will pass unchanged.

Syntax

```
trust dscp
no trust
```

Mode Policy Map Configuration

Usage The DSCP value in the packet is used for lookup, regardless of whether the policy-map has any class-map (with an assigned DSCP) attached to it.

Examples To enable the premark-dscp map lookup for policy-map `pmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# trust dscp
```

To disable the premark-dscp map lookup for policy-map `pmap1`, use the commands:

```
awplus# configure terminal
awplus(config)# policy-map pmap1
awplus(config-pmap)# no trust
```

Related Commands

set bandwidth-class
set cos
set dscp
set queue
trust dscp

wrr-queue disable queues

Use this command to disable an egress queue from transmitting traffic.

The no variant of this command enables an egress queue to transmit traffic.

Syntax

```
wrr-queue disable queues [0][1][2][3][4][5][6][7]
no wrr-queue disable queues [0][1][2][3][4][5][6][7]
```

Parameter	Description
[1][2]...[7]	Selects one or more queues numbered 0 to 7.

Mode Interface Configuration

Examples To enable queues 1-3 to transmit traffic, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# no wrr-queue disable queues 1 2 3
```

To disable queues 1-3 from transmitting traffic, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# wrr-queue disable queues 1 2 3
```

Related Commands show mls qos interface

wrr-queue egress-rate-limit queues

Sets a limit on the amount of traffic that can be transmitted per second from these queues. The default unit is in Kb, but Mb or Gb can also be specified. The minimum is 651Kb.

Syntax

```
wrr-queue egress-rate-limit <bandwidth> queues
    {0}[1][2][3][4][5][6][7]

no wrr-queue egress-rate-limit <bandwidth> queues
    {0}[1][2][3][4][5][6][7]
```

Parameter	Description
<bandwidth>	Bandwidth <1-10000000 kbits> (usable units: k, m, g).
{0}[1]...[7]	Selects one or more queues to apply the bandwidth limit to as specified in the preceding *<bandwidth>* parameter. Then apply a priority in the range <0-7> for each selected queue. For example, to apply priorities 1, 2 and 3 to queues 0, 1 and 2 enter queues 1 2 3. {0} [1] . . . [7] indicates a queue for a priority <0-7>.

Mode Interface Configuration

Example To set enable egress rate limiting on queues 0, 1 and 2 with the priorities 1, 2 and 3, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# wrr-queue egress-rate-limit 500M
                   queues 1 2 3
```

Related Commands show mls qos interface

wrr-queue group weight queues

Configures weighted round-robin based scheduling on the specified egress queues on switch port interfaces and static aggregated interfaces.

The queues can be placed into either group 1 or group 2. Both groups are still serviced in a round-robin order according to the specified weights, but all queues in group 1 must be empty before any packets in group 2 can be sent. The weights are specified as ratio's relative to each other.

Note that switch port interfaces or static aggregated interfaces within a round robin group must be contiguous.

Syntax

```
wrr-queue group <1-2> weight <6-255> queues {0}[1][2]3][4][5][6][7]
```

Parameter	Description
<1-2>	WRR group 1 or 2.
<6-255>	Weight.
`{0}[1]...[7]`	Egress queues 0-7 to select and assign a priority in the range <0-7>. The queue number is indicated by the order of entry. For example, queue 1 2 assigns priority 1 and 2 to queues 0 and 1 due to the order of entry. Queue 0 is a required queue.

Mode Interface Configuration for both switch port interfaces and static aggregated interfaces.

Usage Weighted round-robin based scheduling may be applied to switch port interfaces (for example, `awplus(config)#interface port1.0.2`) and to static aggregated interfaces (for example, `awplus(config)#interface sa2`).

Examples To configure wrr-queue group `1` weight `6` queues `0 1 2` on the switch port interface `port1.0.1`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# wrr-queue group 1 weight 6 queues 0 1 2
```

To configure a static aggregated interface `sa2` on switch port interface `port1.0.2` and configure wrr-queue group `2` weight `9` queues `0 1` on interface `sa2`, use these commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# static-channel-group 2
awplus(config-if)# exit
awplus(config)# interface sa2
awplus(config-if)# wrr-queue group 2 weight 9 queues 0 1
```

Related Commands priority-queue
show mls qos interface

wrr-queue queue-limit

Sets the percentages of a ports total buffer pool that each queue is allowed to use. This queue limit is applicable no matter what type of scheduling is configured for the specified queues (i.e. WRR or strict priority).

Syntax

```
wrr-queue queue-limit <1-100> <1-100> <1-100> <1-100> <1-100> <1-100>
    <1-100> <1-100>

no wrr-queue queue-limit
```

Parameter	Description
<1-100>	Queue ratio for Queue 0.
<1-100>	Queue ratio for Queue 1.
<1-100>	Queue ratio for Queue 2.
<1-100>	Queue ratio for Queue 3.
<1-100>	Queue ratio for Queue 4.
<1-100>	Queue ratio for Queue 5.
<1-100>	Queue ratio for Queue 6.
<1-100>	Queue ratio for Queue 7.

Mode Interface Configuration

Usage Note that for ports on the XEM-2XP module, the portion of the port's buffer pool that is assigned to each queue is divided by three, with one third applied to each of the three drop precedence colors, red, green, and yellow.

Where no color metering is applied, the queue limit is effectively reduced to a third of the configured value, because in this situation all traffic is classed as green. For example, if the overall queue size available is 792 frames, and equal portions (12.5% of 792 = 99 frames) are assigned to each queue, then 33 frames are assigned to each of the three drop precedence colors. Where no color metering is applied, all traffic is (by default) defined as green, and so is allocated 33 frames per queue. Tail dropping is then applied when each queue is only one third full.

On ports other than the XEM-2XP, no per precedence queuing is applied; therefore in the above example all 99 frames per queue would be available.

Example To configure a wrr-queue queue-limit on `port1.0.1` to `port1.0.12` for each queue, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1-port1.0.12
awplus(config-if)# wrr-queue queue-limit 12 12 12 12 12 12 12
12
```

Related Commands show mls qos interface

Chapter 62: 802.1X Introduction and Configuration

Introduction 62.2
The 802.1X Implementation 62.2
Configuring 802.1X 62.2

Introduction

The IEEE Standard 802.1X provides a method of restricting access to networks based on authentication information. 802.1X provides port-based network access control for devices connected to the Ethernet. This allows a network controller to restrict external devices from gaining access to the network behind an 802.1X controlled port. External devices that wish to access services via a port under 802.1X control must firstly authenticate themselves and gain authorization before any packets originating from, or destined for, the external device are allowed to pass through the 802.1X controlled port.

The 802.1X Implementation

802.1X port access control is achieved by making devices attached to a controlled port authenticate themselves via communication with an authentication server before these devices are allowed to access the network behind the controlled port.

Authentication is required on a per-port basis. The main components of an 802.1X implementation are:

- the authenticator - the port on this device that wishes to enforce authentication before allowing access to services that are accessible behind it.
- the supplicant - the port that wishes to access services offered by the authenticator's system. The supplicant may be a port on a PC or other device connected to this device.
- the authentication server - a device that uses the authentication credentials supplied by the supplicant, via the authenticator, to determine if the authenticator should grant access to its services.

Configuring 802.1X

The following example explains how to configure 802.1X. In this example, the RADIUS Server keeps the Client information, validating the identity of the Client and updating the switch about the authentication status of the client. The switch is the physical access between the two clients and the server. It requests information from the client, relays information to the server and then back to the client.

To configure 802.1X authentication, first enable authentication on `port1.0.1` and `port1.0.2` and then specify the RADIUS Server IP address and port.

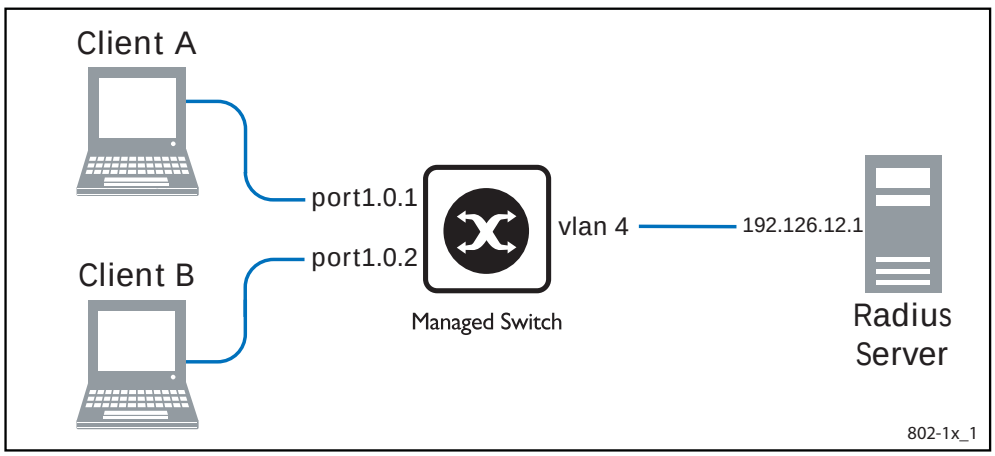

Table 62-1: 802.1X configuration on the switch

awplus#	
configure terminal	Enter the Global Configuration mode.
awplus(config)#	
aaa authentication dot1x default group radius	Enable authentication globally.
awplus(config)#	
interface port1.0.1	Specify the interface (port1.0.1) to be configured and enter the Interface mode.
awplus(config-if)#	
dot1x port-control auto	Enable authentication (via RADIUS) on port1.0.1.
awplus(config-if)#	
dot1x control-direction both	Block traffic in both directions, other than authentication packets, until authentication is complete.
awplus(config-if)#	
exit	Exit the Interface Configuration mode and enter the Global Configuration mode.
awplus(config)#	
interface port1.0.2	Specify the interface (port1.0.2) you are configuring and enter the Interface mode.
awplus(config-if)#	
dot1x port-control auto	Enable authentication (via RADIUS) on port1.0.2.
awplus(config-if)#	
exit	Exit the Interface Configuration mode and enter the Global Configuration mode.
awplus(config)#	
radius-server host 192.126.12.1 auth-port 1812	Specify the RADIUS Server address (192.126.12.1) and authentication port.
awplus(config)#	
radius-server key secret	Specify the shared key secret between the RADIUS server and the client.
awplus(config)#	
interface vlan4	Specify the vlan (vlan4) to be configured and enter the Interface mode.
awplus(config-if)#	
ip address 192.126.12.2/24	Set the IP address on vlan4.

Command List

This chapter provides an alphabetical reference of commands used to configure 802.1X port access control. For more information, see Chapter 62, 802.1X Introduction and Configuration.

debug dot1x

Use this command to enable 802.1X IEEE Port-Based Network Access Control troubleshooting functions.

Use the no variant of this command to disable this function.

Syntax

```
debug dot1x [all|auth-web|event|nsm|packet|timer]
no debug all dot1x
no debug dot1x [all|auth-web|event|nsm|packet|timer]
```

Parameter	Description
`all`	Used with the no variant of this command exclusively; turns off all debugging for 802.1X.
`auth-web`	Specifies debugging for 802.1X auth-web information.
`events`	Specifies debugging for 802.1X events.
`nsm`	Specifies debugging for NSM messages.
`packet`	Specifies debugging for 802.1X packets.
`timer`	Specifies debugging for 802.1X timers.

Mode Privileged Exec and Global Configuration

Usage This command without any parameters turns on normal 802.1X debug information.

```
awplus# debug dot1x
```

```
awplus# show debugging dot1x
```

```
802.1X debugging status:
  802.1X events debugging is
  802.1X timer debugging is on
  802.1X packets debugging is on
  802.1X NSM debugging is on
```

Examples

```
awplus# debug dot1x
awplus# debug dot1x all
```

Related Commands
show debugging dot1x
undebug dot1x

dot1x control-direction

This command sets the direction of the filter for the unauthorized interface.

If the optional in parameter is specified with this command then packets entering the specified port are discarded. The in parameter discards the ingress packets received from the supplicant.

If the optional both parameter is specified with this command then packets entering (ingress) and leaving (egress) the specified port are discarded. The both parameter discards the packets received from the supplicant and sent to the supplicant.

The no variant of this command sets the direction of the filter to both. The port will then discard both ingress and egress traffic.

Syntax

```
dot1x control-direction {in|both}
no dot1x control-direction
```

Parameter	Description
in	Discard received packets from the supplicant (ingress packets).
both	Discard received packets from the supplicant (ingress packets) and transmitted packets to the supplicant (egress packets).

Default The authentication port direction is set to both by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Example To set the port direction to the default (both) for `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no dot1x control-direction
```

To set the port direction to in for `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x control-direction in
```

Validation Commands
show dot1x
show dot1x interface
show auth-mac interface
show auth-web interface

dot1x eap

This command selects the transmit mode for the EAP packet. If the authentication feature is not enabled then EAP transmit mode is not enabled. The default setting discards EAP packets.

Syntax `dot1x eap {discard|forward|forward-untagged-vlan|forward-vlan}`

Parameter	Description
`discard`	Discard.
`forward`	Forward to all ports on the switch.
`forward-untagged-vlan`	Forward to ports with the same untagged VLAN.
`forward-vlan`	Forward to ports with the same VLAN.

Default The transmit mode is set to `discard` EAP packets by default.

Mode Global Configuration

Example To set the transmit mode of EAP packet to `forward` to forward EAP packets to all ports on the switch, use the following commands:

```
awplus# configure terminal
awplus(config)# dot1x eap forward
```

To set the transmit mode of EAP packet to `discard` to discard EAP packets, use the following commands:

```
awplus# configure terminal
awplus(config)# dot1x eap discard
```

To set the transmit mode of EAP packet to `forward-untagged-vlan` to forward EAP packets to ports with the same untagged vlan, use the following commands:

```
awplus# configure terminal
awplus(config)# dot1x eap forward-untagged-vlan
```

To set the transmit mode of EAP packet to `forward-vlan` to forward EAP packets to ports with the same vlan, use the following commands:

```
awplus# configure terminal
awplus(config)# dot1x eap forward-vlan
```

dot1x eapol-version

This command sets the EAPOL protocol version for EAP packets when 802.1X port authentication is applied.

Use the no variant of this command to set the EAPOL protocol version to 1.

The default EAPOL protocol version is version 1.

Syntax

```
dot1x eapol-version {1|2}
no dot1x eapol-version
```

Parameter	Description
1	EAPOL version.
2	EAPOL version.

Default The EAP version for 802.1X authentication is set to 1 by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Example To set the EAPOL protocol version to `2` for `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x eapol-version 2
```

To set the EAPOL protocol version to the default version (1) for interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no dot1x eapol-version
```

Validation Commands show dot1x
show dot1x interface

dot1x initialize interface

This command initializes the 802.1X status on the specified interface, and attempts reauthentication.

Use this command to unauthorize a port, and attempt reauthentication on the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

Syntax `dot1x initialize interface <interface-list>`

Parameter	Description
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example To initialize 802.1X port authentication on the interface `port1.0.2`, use the following command:

```
awplus# dot1x initialize interface port1.0.2
```

To unauthorize switch `port1.0.1` and attempt reauthentication on switch `port1.0.1` enter:

```
awplus# dot1x initialize interface port1.0.1
```

To unauthorize all switch ports for a 24 switch port device and attempt reauthentication enter:

```
awplus# dot1x initialize interface port1.0.1-port1.0.24
```

dot1x keytransmit

This command enables key transmission on the interface specified previously in Interface mode.

The no variant of this command disables key transmission on the interface specified.

Syntax

```
dot1x keytransmit
no dot1x keytransmit
```

Default Key transmission for port authentication is enabled by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage Use this command to enable key transmission over an Extensible Authentication Protocol (EAP) packet between the authenticator and supplicant. Use the no variant of this command to disable key transmission.

Example To enable the key transmit feature on interface `port1.0.2`, after it has been disabled by negation, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x keytransmit
```

To disable the key transmit feature from the default startup configuration on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no dot1x keytransmit
```

Validation Commands show dot1x
show dot1x interface

dot1x max-auth-fail

Use this command to configure the maximum number of login attempts for a supplicant (client device) using the auth-fail vlan feature, when using 802.1X port authentication on an interface.

The no variant of this command resets the maximum login attempts for a supplicant (client device) using the auth-fail vlan feature, to the default configuration of 3 login attempts.

Syntax

```
dot1x max-auth-fail <0-10>
no dot1x max-auth-fail
```

Parameter	Description
<0-10>	Specify the maximum number of login attempts for supplicants on an interface using 802.1X port authentication.

Default The default maximum number of login attempts for a supplicant on an interface using 802.1X port authentication is three (3) login attempts.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage This command sets the maximum number of login attempts for supplicants on an interface. The supplicant is moved to the auth-fail VLAN from the Guest VLAN after the number of failed login attempts using 802.1X authentication is equal to the number set with this command.

See the related auth auth-fail vlan command on page 65.3. See also the section "Failed authentication VLAN" on page 64.11 for information about the auth-fail VLAN feature.

See the section "Limitations on allowed feature combinations" on page 64.12 for information about restrictions regarding combinations of authentication enhancements working together.

Examples To configure the maximum number of login attempts for a supplicant on interface `port1.0.2` to a single (`1`) login attempt, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x max-auth-fail 1
```

To configure the maximum number of login attempts for a supplicant on interface `port1.0.2` to the default number of three (`3`) login attempts, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no dot1x max-auth-fail
```

Validation Commands show running-config

Related Commands auth auth-fail vlan
dot1x max-reauth-req
show dot1x interface

dot1x max-reauth-req

This command sets the number of reauthentication attempts before an interface is unauthorized.

The no variant of this command resets the reauthentication delay to the default.

Syntax

```
dot1x max-reauth-req <1-10>
no dot1x max-reauth-req
```

Parameter	Description
<1-10>	Specify the maximum number of reauthentication attempts for supplicants on an interface using 802.1X port authentication.

Default The default maximum reauthentication attempts for interfaces using 802.1X port authentication is two (2) reauthentication attempts, before an interface is unauthorized.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage Use this command to set the maximum reauthentication attempts after failure.

Examples To configure the maximum number of reauthentication attempts for interface `port1.0.2` to a single (1) reauthentication request, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x max-reauth-req 1
```

To configure the maximum number of reauthentication attempts for interface `port1.0.2` to the default maximum number of two (2) reauthentication attempts, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no dot1x max-reauth-req
```

Validation Commands show running-config

Related Commands dot1x max-auth-fail
show dot1x interface

dot1x port-control

This command enables 802.1X port authentication on the interface specified, and sets the control of the authentication port. When port-control is set to auto, the 802.1X authentication feature is executed on the interface, but only if the aaa authentication dot1x command has been issued.

The no variant of this command disables the port authentication on the interface specified.

Syntax

```
dot1x port-control {force-unauthorized|force-authorized|auto}
no dot1x port-control
```

Parameter	Description
`force-unauthorized`	Force port state to unauthorized. Specify to force a port to always be in an unauthorized state.
`force-authorized`	Force port state to authorized. Specify to force a port to always be in an authorized state.
`auto`	Allow port client to negotiate authentication. Specify to enable authentication on port.

Default 802.1X port control is disabled by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage Use this command to force a port state. Note that all dot1x commands can only be applied to switch ports. They cannot be applied to dynamic (LACP) or static channel groups.

Example To enable port authentication on the interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x port-control auto
```

To enable port authentication force authorized on the interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x port-control force-authorized
```

To disable port authentication on the interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no dot1x port-control
```

Validation Commands show dot1x interface

Related Commands aaa authentication dot1x

dot1x timeout tx-period

This command sets the transmit timeout for the authentication request on the specified interface.

The no variant of this command resets the transmit timeout period to the default (30 seconds).

Syntax

```
dot1x timeout tx-period <1-65535>
no dot1x timeout tx-period
```

Parameter	Description
<1-65535>	Seconds.

Default The default transmit period for port authentication is 30 seconds.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage Use this command to set the interval between successive attempts to request an ID.

Example To set the transmit timeout period to 5 seconds on interface `port1.0.2`, use the below commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x timeout tx-period 5
```

To reset transmit timeout period to the default (30 seconds) on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no dot1x timeout tx-period
```

Validation Commands show dot1x
show dot1x interface

show debugging dot1x

Use this command to display the 802.1X debugging option set.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show debugging dot1x`

Mode User Exec and Privileged Exec

Usage This is a sample output from the `show debugging dot1x` command.

```
awplus# debug dot1x

awplus# show debugging dot1x
```

```
802.1X debugging status:
  802.1X events debugging is on
  802.1X timer debugging is on
  802.1X packets debugging is on
  802.1X NSM debugging is on
```

Example

```
awplus# show debugging dot1x
```

Related Commands debug dot1x

show dot1x

This command shows authentication information for dot1x (802.1X) port authentication.

If you specify the optional all parameter then this command also displays all authentication information for each port available on the switch.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show dot1x [all]`

Parameter	Description
`all`	All.

Mode Privileged Exec

Example

```
awplus# show dot1x all
```

Table 63-1: Example output from the **show dot1x** command

```
awplus# show dot1x all

show dot1x diagnostics

This command shows 802.1X authentication diagnostics for the specified interface (optional), which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

If no interface is specified then authentication diagnostics are shown for all interfaces.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show dot1x diagnostics [interface <interface-list>]`

Parameter	Description
`interface`	Specify a port to show.
`<interface-list>`	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example See the sample output below showing 802.1X authentication diagnostics for `port1.0.12`:

```
awplus# show dot1x diagnostics interface port1.0.12
```

Output Figure 63-1: Example output from the **show dot1x diagnostics** command

```
Authentication Diagnostics for interface port1.0.12
    Supplicant address: 00d0.59ab.7037

      BackendAuthSuccess: 1
```

show dot1x interface

This command shows the status of 802.1X port-based authentication on the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

Use the optional diagnostics parameter to show authentication diagnostics for the specified interfaces. Use the optional sessionstatistics parameter to show authentication session statistics for the specified interfaces. Use the optional statistics parameter to show authentication diagnostics for the specified interfaces. Use the optional supplicant parameter to show the supplicant state for the specified interfaces.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax

```
show dot1x interface <interface-list>
   [diagnostics|sessionstatistics|statistics|supplicant [brief]]
```

Parameter	Description
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.
`diagnostics`	Diagnostics.
`sessionstatistics`	Session Statistics.
`statistics`	Statistics.
`supplicant`	Supplicant.
`brief`	Brief summary of supplicant state.

Mode Privileged Exec

Example See the sample output below showing 802.1X authentication status for `port1.0.12`:

```
awplus# show dot1x interface port1.0.12
```

Table 63-2: Example output from the **show dot1x interface** command for a port

```
awplus#show dot1x interface port1.0.12
Authentication info for interface port1.0.12
    portEnabled: true - portControl: Auto
    portStatus: Authorized
    reAuthenticate: disabled
    reAuthPeriod: 3600

Table 63-3: Parameters in the output of the **show dot1x interface** command

Parameter	Description
portEnabled	Interface operational status (Up-true/down-false).
portControl	Current control status of the port for 802.1X control.
portStatus	802.1X status of the port (authorized/unauthorized).
reAuthenticate	Reauthentication enabled/disabled status on port.
reAuthPeriod	Value holds meaning only if reauthentication is enabled.
abort	Indicates that authentication should be aborted when set to true.
fail	Indicates failed authentication attempt when set to false.
start	Indicates authentication should be started when set to true.
timeout	Indicates authentication attempt timed out when set to true.
success	Indicates authentication successful when set to true.
state	Current 802.1X operational state of interface.
mode	Configured 802.1X mode.
reAuthCount	Reauthentication count.
quietperiod	Time between reauthentication attempts.
reAuthMax	Maximum reauthentication attempts.
BE	Backend authentication state machine variables and constants.
state	State of the state machine.
reqCount	Count of requests sent to server.
suppTimeout	Supplicant timeout.
serverTimeout	Server timeout.
maxReq	Maximum requests to be sent.
CD	Controlled Directions State machine.
adminControlledDirections	Administrative value (Both/In).
operControlledDirections	Operational Value (Both/In).
KR	Key receive state machine.

Table 63-3: Parameters in the output of the **show dot1x interface** command (cont.)

Parameter	Description
`rxKey`	True when EAPOL-Key message is received by supplicant or authenticator. false when key is transmitted.
`KT`	Ket Transmit State machine.
`keyAvailable`	False when key has been transmitted by authenticator, true when new key is available for key exchange.
`keyTxEnabled`	Key transmission enabled/disabled status.

Related Commands

show auth-web diagnostics
show dot1x sessionstatistics
show dot1x statistics interface
show dot1x supplicant interface

show dot1x sessionstatistics

This command shows authentication session statistics for the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show dot1x sessionstatistics [interface <interface-list>]`

Parameter	Description
`interface`	Specify a port to show.
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example See sample output below showing 802.1X (`dot1x`) authentication session statistics for `port1.0.12`:

```
awplus# show dot1x sessionstatistics interface port1.0.12
```

```
Authentication session statistics for interface port1.0.12
    session user name: manager
        session authentication method: Remote server
        session time: 19440 secs
        session terminat cause: Not terminated yet
```

show dot1x statistics interface

This command shows the authentication statistics for the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show dot1x statistics interface <interface-list>`

Parameter	Description
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example See sample output below showing 802.1X authentication statistics for `port1.0.12`:

```
awplus# show dot1x statistics interface port1.0.12
```

```
802.1X statistics for interface port1.0.12

show dot1x supplicant

This command shows the supplicant state of the authentication mode set for the switch.

This command shows a summary when the optional brief parameter is used.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show dot1x supplicant [<macadd>] [brief]`

Parameter	Description
`<macadd>`	MAC (hardware) address of the Supplicant.
`brief`	Brief summary of the Supplicant state.

Mode Privileged Exec

Example See sample output below showing the 802.1X authenticated supplicant on the switch:

```
awplus# show dot1x supplicant
```

```
authenticationMethod: dot1x
totalSupplicantNum: 1
authorizedSupplicantNum: 1
macBasedAuthenticationSupplicantNum: 0
dot1xAuthenticationSupplicantNum: 1
webBasedAuthenticationSupplicantNum: 0
Supplicant name: manager
Supplicant address: 00d0.59ab.7037
    authenticationMethod: dot1x
    portStatus: Authorized - currentId: 4
    abort:F fail:F start:F timeout:F success:T
    PAE: state: Authenticated - portMode: Auto
    PAE: reAuthCount: 0 - rxRespId: 0
    PAE: quietPeriod: 60 - maxReauthReq: 2 - txPeriod: 30
    BE: state: Idle - reqCount: 0 - idFromServer: 3
    BE: suppTimeout: 30 - serverTimeout: 30
    CD: adminControlledDirections: in - operControlledDirections:
in
    CD: bridgeDetected: false
    KR: rxKey: false
    KT: keyAvailable: false - keyTxEnabled: false
```

See sample output below showing the supplicant on the switch using the `brief` parameter:

```
awplus# show dot1x supplicant 00d0.59ab.7037 brief
```

```
Interface port1.0.12
    authenticationMethod: dot1x
    totalSupplicantNum: 1
    authorizedSupplicantNum: 1
        macBasedAuthenticationSupplicantNum: 0
        dot1xAuthenticationSupplicantNum: 1
        webBasedAuthenticationSupplicantNum: 0
Interface VID Mode MAC Address Status IP Address Username
========= === ==== ============ ======= =========== ========
port1.0.12 2 D 00d0.59ab.7037Authenticated 192.168.2.201 manager
```

Related Commands show dot1x supplicant interface

show dot1x supplicant interface

This command shows the supplicant state of the authentication mode set for the interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

This command shows a summary when the optional brief parameter is used.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show dot1x supplicant interface <interface-list> [brief]`

Parameter	Description
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.
`brief`	Brief summary of the Supplicant state.

Mode Privileged Exec

Example See sample output below showing the supplicant on the interface `port1.0.19`:

```
awplus# show dot1x supplicant interface port1.0.19
```

```
Interface port1.0.19
 authenticationMethod: dot1x
 totalSupplicantNum: 1
 authorizedSupplicantNum: 1
   macBasedAuthenticationSupplicantNum: 0
   dot1xAuthenticationSupplicantNum: 1
   webBasedAuthenticationSupplicantNum: 0
   otherAuthenticationSupplicantNum: 0

 Supplicant name: VCSPCVLAN10
 Supplicant address: 0000.cd07.7b60
   authenticationMethod: 802.1X
   portStatus: Authorized - currentId: 3
   abort:F fail:F start:F timeout:F success:T
   PAE: state: Authenticated - portMode: Auto
   PAE: reAuthCount: 0 - rxRespId: 0
   PAE: quietPeriod: 60 - maxReauthReq: 2
   BE: state: Idle - reqCount: 0 - idFromServer: 2
   CD: adminControlledDirections:in -

Authentication Introduction

Authentication commands enable you to specify three different types of device authentication: 802.1X authentication, MAC authentication, and Web-authentication. These are collectively called tri-authentication when applied to authenticate any devices connected to switch ports.

Tri-Authentication Introduction

The switch supports three types of authentication for devices that connect to switch ports:

- 802.1X authentication of devices connecting to switch ports
- MAC authentication of devices connecting to switch ports
- Web-authentication of devices connecting to switch ports

All three types can be configured to run simultaneously on a switch port. The simultaneous configuration and authentication of all three types on a port is called tri-authentication.

Tri-Authentication Configuration

Follow the below three steps to configure tri-authentication across a range of switch ports:

Step 1: Define the RADIUS Server:

Define the RADIUS Server where the switch will send authentication requests using the below commands:

```
awplus# configure terminal
awplus(config)# radius-server host <ip-address> key
<key-string>
```

These commands adds the RADIUS Server address and set parameters to the RADIUS server. The key parameter specifies the secret key for the server.

Note

The RADIUS Server, where the switch sends authentication requests, could be the switch's own Local RADIUS Server. For information on how to configure Local RADIUS Server see Chapter 72, Local RADIUS Server Introduction and Configuration.

Step 2: Define the default authentication server lists:

Define the default authentication server lists for 802.1X authentication, Web-based authentication, and MAC-based authentication:

```
awplus# configure terminal
awplus(config)# aaa authentication dot1x default group radius
awplus(config)# aaa authentication auth-web default group
radius
awplus(config)# aaa authentication auth-mac default group
radius
```

Step 3: Configure 802.1X, Web-based, and MAC-based authentication:

Configure 802.1X authentication, Web-authentication, MAC-authentication on switch ports to attach supplicant devices:

```
awplus# configure terminal
awplus(config)# interface <interface-range>
awplus(config-if)# switchport mode access
awplus(config-if)# switchport access vlan 1
awplus(config-if)# auth-web enable
awplus(config-if)# auth-mac enable
awplus(config-if)# dot1x port-control auto
awplus(config-if)# auth dynamic-vlan-creation
```

Configuring a Guest VLAN

You can configure 802.1X to accept a Dynamic VLAN assignment, or fall back to a Guest VLAN upon failure.

If 802.1X authentication has been configured on access ports in the network, you might still want to provide limited network access to those users whose devices do not have 802.1x supplicant enabled, or who have unrecognized authentication credentials.

The mechanism to achieve this is known as a guest VLAN. The idea is that if the users device fails 802.1X authentication, or is not even performing any 802.1X authentication, then its connection port can be put into the Guest VLAN.

To configure a switch to perform 802.1x authentication, and assign VLAN IDs to ports where devices authentication successfully, and put non-authenticated users into a Guest VLAN, proceed as follows:

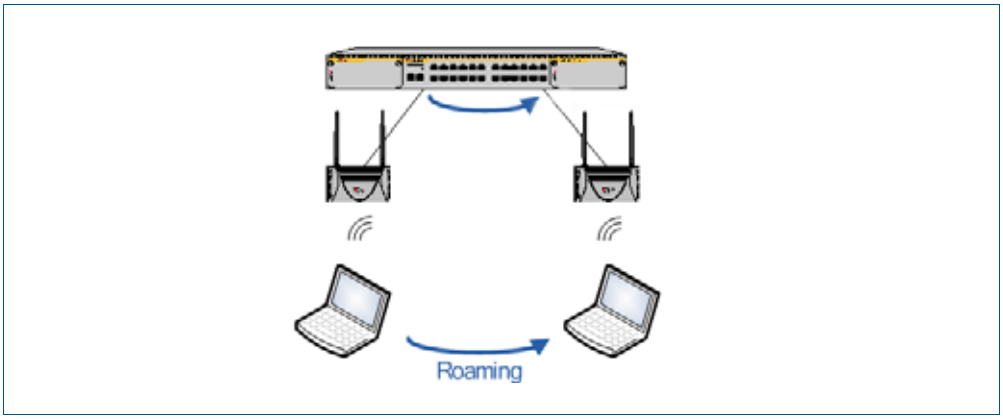
```
awplus# configure terminal
awplus(config)# radius-server host <ip-address> key
<key-string>
awplus(config)# aaa authentication dot1x default group
radius
awplus(config)# interface <interface-range>
awplus(config-if)# switchport mode access
awplus(config-if)# dot1x port-control auto
awplus(config-if)# auth dynamic-vlan-creation
awplus(config-if)# auth guest-vlan 100
```

Roaming Authentication

When network security is required, the usability of network security must be considered. The Roaming Authentication feature improves the usability of network security by enabling users to move within the network without requiring them to re-authenticate each time they move.

If a supplicant (client device) moves from one wireless access point to another wireless access point, and the wireless access points are connected to different ports, then the switch (authenticator) recognizes that the supplicant has been authenticated and accepts the supplicant without requiring re-authentication.

Figure 64-1: Diagram showing Roaming Authentication running on a standalone switch

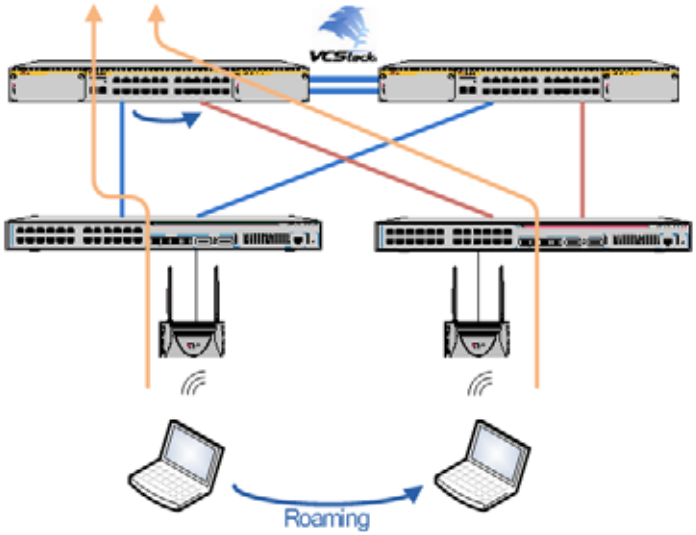


Web and MAC authentication are the authentication methods in a Wireless LAN environment, and 802.1X is the authentication method used for supplicants attached to edge switches.

Roaming Authentication is normally enabled using the auth roaming enable command on page 65.17 command. However, Roaming Authentication has been extended (with the auth roaming disconnected command on page 65.15) to work where an interface is link down. This allows you to enable supplicants to move from authenticated interfaces that are link down, without requiring re-authentication.

Roaming Authentication is available for use with the VCStack feature, and is available on static and dynamic (LACP) channel group interfaces.

Figure 64-2: Diagram showing Roaming Authentication running with VCStack



Roaming Authentication Overview

Without the Roaming Authentication feature enabled, if a supplicant moves from one switch port to another switch port, the supplicant's authenticated status, authentication, and assigned VLAN is deleted and the supplicant is re-authenticated so the supplicant can access the network, and all traffic from the supplicant is dropped while the supplicant is being re-authenticated.

With the Roaming Authentication feature enabled, a switch port inherits the status of a supplicant from the switch port that the supplicant was moved from. If the Roaming Authentication feature is enabled on a switch, then once a supplicant (client device) is authenticated on the switch it does not have to be re-authenticated if it moves between ports of that switch. Supplicant traffic is not dropped because there is no delay for re-authentication, during which the supplicant cannot access the network.

For example, when the Roaming Authentication feature is used in an wireless LAN environment with wireless access points, then the wireless clients can roam between wireless access points connected to different switch ports without re-authentication.

The Roaming Authentication feature also supports VCStack operation and works on defined static channel group (static aggregators) and dynamic channel group (LACP) interfaces. When VCStack and Roaming Authentication features are used together, the status of a supplicant is inherited from one aggregated interface to another aggregated interface over the stack.

See the auth roaming disconnected command on page 65.15 and the auth roaming enable command on page 65.17 for further information about configuring Roaming Authentication.

Roaming Authentication Feature Interactions

When the Roaming Authentication feature is disabled, a supplicant must be re-authenticated on the destination interface when it roams. When the Roaming Authentication is enabled, the following supplicant authentication status and information is inherited from the source interface:

- Authentication status
- Authentication method
- Supplicant MAC address
- Supplicant IP address
  (if an authenticated interface is configured for Web authentication)
- Supplicant name
- Authorized dynamic VLAN ID
- Authorized RADIUS server
- Reauthentication timer
  (if configured using the auth timeout reauth-period command on page 65.22)

Roaming Authentication is only supported between interfaces with the same authentication configuration. If source and destination interfaces have different authentication configuration then the supplicant will be re-authenticated at the destination interface.

When the host mode is set with the auth host-mode command on page 65.11, a supplicant is not authenticated on a destination interface, and the authentication status is deleted on the source interface.

When a supplicant moves from an interface with authentication configured to an interface without authentication configured, the supplicant's authentication status is deleted.

A supplicant is re-authenticated when it moves to a destination interface that is configured on a different VLAN than the VLAN that is configured for the source interface.

See the following Roaming Authentication feature interactions:

- The Roaming Authentication feature will not function with Dynamic VLANs.
- The Roaming Authentication feature will not function with Guest VLANs.

When the Roaming Authentication feature is configured for use on a stack with the VCStack feature, note that supplicants are initialized and re-authenticated if a VCStack failover occurs.

Unauthenticated Supplicant Traffic

When any authentication is configured on a switch port, the question arises as to what the switch does with packets that arrive into the switch port from unauthenticated supplicants.

Unauthenticated supplicants fall into three categories listed below:

- Newly attached supplicants, which are still in the process of their first authentication attempt
- Supplicants that have made an authentication attempt, but have failed authentication
- Supplicants that have been attached, but have not made an authentication attempt. For example, on a port that has only 802.1x authentication enabled, any supplicant that has no 802.1x client software will not be able to attempt 802.1x authentication.

In switches that are running the AlliedWare Plus™ Operating System, packets from all these three categories of unauthenticated supplicants are treated equally; no distinction is made between these three categories. The treatment of the traffic from unauthenticated supplicants does, however, depend on two factors:

- Whether a Guest VLAN has been configured on the switch port to which the supplicant is attached
- Whether Web authentication has been configured on the switch port to which the supplicant is attached

The rules governing the treatment of packets from unauthenticated supplicants are laid out in the table below:.

Table 64-1: Treatment of packets from unauthenticated supplicants

Switch port configuration	No Guest VLAN configured	Guest VLAN configured
Web authentication configured	Packets from unauthenticated supplicants are associated with the Native VLAN of the port. Packets from unauthenticated supplicants are processed according these rules: ■ Packets destined to the WebAuth server IP address/TCP port are forwarded to the server (which may well be the switch itself). ■ DHCP packets are sent to the CPU, to be processed by a local DHCP server, or relayed to another DHCP server, depending on the configuration of the switch. ■ DNS packets are forwarded to the CPU, and then sent on to a DNS server, if the switch is configured with a DNS server address. ■ ARP packets are forwarded to the CPU, and an ARP entry for the supplicant is learnt. ■ If web-auth forwarding is enabled for particular types of packets, then those packets will be forwarded within the Native VLAN ■ All other packets are dropped.	Packets from unauthenticated supplicants are associated with the Guest VLAN of the port. Packets from unauthenticated supplicants are processed according to these rules: ■ Packets destined to the WebAuth server IP address/TCP port are forwarded to the server (which may well be the switch itself). ■ DHCP packets are sent to the CPU, to be processed by a local DHCP server, or relayed to another DHCP server, depending on the configuration of the switch. ■ DNS packets are forwarded to the CPU, and then sent on to a DNS server, if the switch is configured with a DNS server address. ■ ARP packets are forwarded to the CPU, and an ARP entry for the supplicant is learnt. ■ Drop all other packets destined to the IP address of the Guest VLAN. ■ Layer 2 forward packets destined to other addresses within the Guest VLAN. ■ All other packets are dropped.
No Web authentication configured	All non-eap packets from unauthenticated supplicants are dropped.	Packets from unauthenticated supplicants are associated with the Guest VLAN of the port. The packets are processed according to these rules: ■ Drop packets destined to the IP address of the Guest VLAN. ■ Layer 2 forward packets destined to other addresses within the Guest VLAN. ■ Drop all other packets.

Deciding when a supplicant fails authentication

Although the treatment of packets from unauthenticated supplicants does not differentiate between the three categories of supplicant, it is still useful to know for sure when the switch decides that a supplicant has failed authentication.

The rules for deciding that a supplicant has failed authentication are listed below for each type of authentication available:

Deciding when a supplicant fails 802.1X authentication

If the supplicant responds to EAP authentication requests, and the supplicant's authentication information is sent to the RADIUS server, and the RADIUS server replies with an Authentication-Reject, then the supplicant is immediately deemed to have failed authentication.

If the supplicant does not respond to EAP authentication requests, then the switch will resend the authentication requests up to a maximum number of attempts set by the command dot1x max-reauth-req (the default is 2). The interval between the attempts is set by the command dot1x timeout tx-period (the default is 30 seconds). If the supplicant still has not responded after this, it is deemed to have not attempted authentication.

See Chapter 63, 802.1X Commands for 802.1X authentication command information.

Deciding when a supplicant fails Web authentication

As soon as the supplicant attempts any web-browsing, the switch will intercept the web session, and present the supplicant with an authentication request page. If the user enters a username and password, and clicks the login button, then the switch will send the username and password to the RADIUS server. If the RADIUS server replies with an Authentication-Reject, then the supplicant is immediately deemed to have failed authentication.

Until the supplicant has attempted any web-browsing, or has received the authentication request page, but not yet clicked the login button, the supplicant is deemed to be not yet authenticated (as against not able to authenticate).

See Chapter 65, Authentication Commands for Web authentication command information.

Deciding when a supplicant fails MAC authentication

As soon as the supplicant sends any packet, the source MAC address from the packet will be sent to the RADIUS server for authentication. If the RADIUS server replies with an Authentication-Reject, then the supplicant is immediately deemed to have failed authentication.

With MAC auth there really is no concept of not-yet-attempted authentication, because authentication is attempted as soon as a supplicant sends a packet.

See Chapter 65, Authentication Commands for MAC authentication command information.

Authentication Enhancements

The authentication enhancements introduced in this release fall into three areas:

- Web-authentication Enhancements
  Improvements to Web-authentication
- Guest VLAN Enhancements
  Increased flexibility in the operation of the Guest VLAN
- Failed authentication VLAN
  Introduction of the auth-fail VLAN

See the section "Limitations on allowed feature combinations" on page 64.12 for information about restrictions regarding combinations of authentication enhancements working together.

Web-authentication Enhancements

Web-authentication can now operate as seamlessly as 802.1X authentication.

In previous releases there were limitations in the operation of Web-authentication. In particular, the authenticating switch had to be the default gateway for the client PC, or the user on the client PC had to browse explicitly to the IP address of the switch. As as result, previous web-authentication would not reliably interoperate with a client PC that had static IP configuration.

The aim of the enhancements in this release is to ensure that the client PC user is presented with the Web-authentication login page as soon as they start web browsing to any address, irrespective of the IP configuration (whether or not it is static or dynamic) on their client PC.

There are three aspects to the enhancements that have been implemented in order to do this:

- DHCP Server for Web-authentication
- Interception of clients' ARPs
- Proxy DNS response

DHCP Server for Web-authentication

In previous releases, a DHCP service could be configured on the authenticating switch, serving IP addresses in the subnet used on the Guest VLAN. While this did facilitate Web-authentication for client PCs with dynamic IP configuration, it was not an ideal solution, since the DHCP service was shared between Web-authentication clients and Guest VLAN users.

In this release there is now a DHCP server dedicated to serving IP addresses for use by Web-authentication clients.

See the auth-web-server dhcp ipaddress command on page 65.33 and the auth-web-server dhcp lease command on page 65.34 for details about configuring the Web-authentication DHCP Server.

Interception of clients' ARPs

A client PC's IP communications will always be preceded by sending out ARP (Address Resolution Protocol) requests for host addresses in its local subnet, or for its gateway address. If the IP address and gateway address have been statically configured on the client PC, and the subnet used in this static configuration is different to that on the authenticating switch, then the ARP requests will receive no reply, and the PC will not begin IP communications.

So, a switch operating as a Web Authenticator needs a method for replying to arbitrary ARP requests, to enable the client PC to proceed to the HTTP session required to perform Web-authentication.

The Web-authentication server can operate in three modes:

- No interception: only responds to ARP requests for its own IP address (this is the operation of the Web-authentication server in previous versions of AlliedWare Plus™).
- Intercept mode: will respond to ARP requests from any IP address that is in the same subnet as the switch's own IP address, and will provide its own MAC address in the ARP reply, irrespective of what IP address (within its own subnet) was being requested.
- Promiscuous mode: will respond to any ARP request, irrespective of whether the requested IP address is in the same subnet as the switch's IP address or not. It will provide its own MAC address in the ARP reply, irrespective of what IP address was being requested.

The addition of this functionality allows you to configure the Web-authentication server to interoperate with any static IP configuration on a client PC.

See the auth-web-server mode command on page 65.37 for command information about setting the Web-authentication mode.

Proxy DNS response

Typically, an HTTP session from a web browser is preceded by a DNS request for the IP address of the website the user wishes to browse to. If the DNS request does not receive a reply, then the web browser will never proceed to connect an HTTP session.

Hence the Web-authentication server needs a mechanism to reply to DNS requests, so that the Web-authentication session can begin. The Web-authentication modes also control the operation of Proxy DNS replies from the Web-authentication server as listed below:

- No interception: does not respond to DNS requests
- Intercept mode: responds to DNS request whose source IP address is within the same subnet as the IP address on the switch. The IP address provided as the resolution of the DNS lookup is the switch's own IP address, so that the subsequent HTTP traffic will be directed to the switch.
- Promiscuous mode: responds to DNS requests from any source IP address. The IP address provided as the resolution of the DNS lookup is the switch's own IP address, so that the subsequent HTTP traffic will be directed to the switch.

The combination of these enhancements ensure that, irrespective of the IP configuration on the client PC, Web-authentication will proceed smoothly.

See the auth-web-server mode command on page 65.37 for command information about setting the Web-authentication mode.

Guest VLAN Enhancements

In previous releases, traffic from unauthenticated supplicants in the Guest VLAN could only be L2 switched within the Guest VLAN.

As a result, it was not possible for DHCP requests from host in the Guest VLAN to be relayed to a DHCP server in another VLAN. Hence, for hosts in the Guest VLAN to obtain DHCP leases, the DHCP Server needed to have an interface in the Guest VLAN, or the authenticating switch needed to act as a DHCP Server. Either of these options could be inconvenient, or possibly even something of a security risk.

Additionally, supplicants in the Guest VLAN who needed to log into a Domain Controller, as part of becoming integrated into a NAC solution, could not access the Domain Controller if it was in another VLAN.

In this release, there is now an option to enable routing from the Guest VLAN. By default, traffic from unauthenticated supplicants in the Guest VLAN will still only be L2 switched within the Guest VLAN. But, if the routing parameter for the auth guest vlan command is configured, then the switch will route unauthenticated supplicants' traffic to other VLANs if required, and will relay their DHCP requests to servers in other VLANs if required.

See the auth guest-vlan command on page 65.9 for command information about Guest VLAN feature enhancements.

Failed authentication VLAN

The auth-fail VLAN feature allows the Network Administrator to separate the supplicants who attempted authentication, but failed, from the supplicants who did not attempt authentication.

This feature enables the Network Administrator to enact a security policy in which the supplicants who fail authentication are given extremely limited access, or are given access to remedial applications.

If the Guest VLAN and auth-fail VLAN are both configured on a switch, then a newly connected supplicant initially belongs to the Guest VLAN. If newly connected supplicants attempt 802.1X port authentication or Web-authentication and fail, then they are moved from the Guest VLAN to the auth-fail VLAN.

The criteria for how many failed authentication attempts are allowed before the supplicant is moved to the auth-fail VLAN differs, depending on the authentication method used.

If Web-authentication is used, then the supplicant is moved to the auth-fail VLAN after the first failed attempt. If 802.1X port authentication is used, then the supplicant is moved to the auth-fail VLAN after the number of failed attempts is equal to the value configured by the dot1x max-auth-fail command (by default, three failed 802.1X authentication attempts are allowed).

Note that the auth-fail VLAN feature is not applicable for MAC authentication. Supplicants failing MAC authentication remain in the Guest VLAN and will not move to the auth-fail VLAN.

See the auth auth-fail vlan command on page 65.3 and the dot1x max-auth-fail command on page 63.8 for command information about the failed authentication vlan feature when using 802.1X port authentication on an interface.

Limitations on allowed feature combinations

Note that the Web-authentication feature and enhancements cannot be used with the Guest VLAN or auth-fail VLAN features. For further limitation information see the below tables:

Table 64-2: Interoperation of authentication types with Guest VLAN and auth-fail VLAN

Authentication Type:	Guest VLAN (without routing mode)	Guest VLAN (with routing mode)	Failed Authentication VLAN
802.1X Port-based Authentication	No change in functionality from previous releases	Unauthorized supplicant can access Guest VLAN. Use ACL for security on the interface.	Failed authentication supplicant can access auth-fail VLAN. See limitations table below for ACL usage limitation.
MAC Authentication	No change in functionality from previous releases	Unauthorized supplicant can access Guest VLAN. Use ACL for security on the interface.	(Not Available)
Web-based Authentication (without intercept mode)	No change in functionality from previous releases	Unauthorized supplicant can access Guest VLAN. Use ACL for security on the interface.	Failed authentication supplicant can access auth-fail VLAN. See limitations table below for ACL usage limitation.
Web-based Authentication (with intercept mode)	(Not Available)	(Not Available)	(Not Available)

Table 64-3: Interactions between Guest VLAN and auth-fail VLAN

Authentication Feature:	Guest VLAN (without routing mode)	Guest VLAN (with routing mode)	Failed Authentication VLAN
Guest VLAN (without routing mode)	(Not Available)	(Not Available)	Cannot configure ACLs on the Guest VLAN when it is not in routing mode. The Guest VLAN without routing mode has reserved ACLs already attached to it.
Guest VLAN (with routing mode)	(Not Available)	(Not Available)	Configuration of ACLs for additional interface security is recommended.
Failed Authentication VLAN	Cannot configure ACLs on the Guest VLAN when it is not in routing mode. The Guest VLAN without routing mode has reserved ACLs already attached to it.	Configuration of ACLs for additional interface security is recommended.	(Not Available)

Command List

This chapter provides an alphabetical reference for Authentication commands. For more information, see Chapter 64, Authentication Introduction and Configuration, and Chapter 67, AAA Commands.

auth auth-fail vlan

Use this command to enable the auth-fail vlan feature on the specified vlan interface. This feature assigns supplicants (client devices), which have failed port authentication, to the specified VLAN interface.

Use the no variant of this command to disable the auth-fail vlan feature for a specified VLAN interface.

Syntax

```
auth auth-fail vlan <1-4094>
no auth auth-fail vlan
```

Parameter	Description
<1-4094>	Assigns the VLAN ID to any supplicants that have failed port authentication.

Default The auth-fail vlan feature is disabled by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage Use the auth-fail vlan feature when using Web-authentication instead of the Guest VLAN feature, when you need to separate networks where one supplicant (client device) requires authentication and another supplicant does not require authentication from the same interface.

This is because the DHCP lease time using the Web authentication feature is shorter, and the auth fail vlan feature enables assignment to a different VLAN if a supplicant fails authentication.

When using 802.1X port authentication, use a dot1x max-auth-fail command to set the maximum number of login attempts. Three login attempts are allowed by default for 802.1X port authentication before supplicants trying to authenticate are moved from the Guest VLAN to the auth-fail VLAN. See the "dot1x max-auth-fail" on page 63.8 for command information.

See the section "Failed authentication VLAN" on page 64.11 in Chapter 64, Authentication Introduction and Configuration for further overview information about the auth-fail VLAN feature, which allows the Network Administrator to separate the supplicants who attempted authentication, but failed, from the supplicants who did not attempt authentication.

See the section "Limitations on allowed feature combinations" on page 64.12 for information about restrictions regarding combinations of authentication enhancements working together.

Use appropriate ACLs (Access Control Lists) on interfaces for extra security if a supplicant allocated to the designated auth-fail vlan can access the same network as a supplicant on the Guest VLAN. For more information about ACL concepts, and configuring ACLs see Chapter 55, Access Control Lists Introduction. For more information about ACL commands see:

- Chapter 56, IPv4 Hardware Access Control List (ACL) Commands
- Chapter 57, IPv4 Software Access Control List (ACL) Commands
- Chapter 58, IPv6 Hardware Access Control List (ACL) Commands
- Chapter 59, IPv6 Software Access Control List (ACL) Commands

Examples

To enable auth-fail vlan for `port1.0.2` and assign VLAN `100`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth auth-fail vlan 100
```

To disable the auth-fail vlan feature for `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth auth-fail vlan
```

Validation Commands

show running-config

Related Commands

dot1x max-auth-fail
show dot1x
show dot1x interface

auth critical

This command enables the critical port feature on the interface. When the critical port feature is enabled on an interface, and all the RADIUS servers are unavailable, then the interface becomes authorized.

The no variant of this command disables critical port feature on the interface.

Syntax

```
auth critical
no auth critical
```

Default The critical port of port authentication is disabled.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To enable the critical port feature on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth critical
```

To disable the critical port feature on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth critical
```

Validation Commands

show auth-web-server
show dot1x
show dot1x interface
show running-config

auth dynamic-vlan-creation

This command enables and disables the Dynamic VLAN assignment feature.

The Dynamic VLAN assignment feature allows a supplicant (client device) to be placed into a specific VLAN based on information returned from the RADIUS server during authentication, on a given interface.

Use the no variant of this command to disable the Dynamic VLAN assignment feature.

Syntax

```
auth dynamic-vlan-creation [rule {deny|permit}]
no auth dynamic-vlan-creation
```

Parameter	Description
`rule`	VLAN assignment rule.
`deny`	Deny a differently assigned VLAN ID. This is the default rule.
`permit`	Permit a differently assigned VLAN ID.

Default By default, the Dynamic VLAN assignment feature is disabled.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage If the Dynamic VLAN assignment feature is enabled (disabled by default), VLAN assignment is dynamic. If the Dynamic VLAN assignment feature is disabled then RADUS attributes are ignored and configured VLANs are assigned to ports.

The optional rule parameter specifies the VLAN assignment rule when the second supplicant's VLAN ID is different from VLAN ID from the first supplicant. If the deny value is applied with the command then the second supplicant with a different VLAN ID is rejected. If the permit value is applied with the command then the second supplicant with a different VLAN ID is accepted and assigned to the first supplicant's VLAN.

If you issue an auth dynamic-vlan-creation command without an optional rule parameter and a required deny or permit keyword value then a second supplicant with a different VLAN ID is rejected. It is not assigned to the first supplicant's VLAN. Issuing an auth dynamic-vlan-creation command without an optional rule parameter has the same effect as issuing an auth dynamic-vlan-creation rule deny command rejecting supplicants with differing VIDs.

Examples To enable the Dynamic VLAN assignment feature on interface `port1.0.2`, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth dynamic-vlan-creation
```

To disable the Dynamic VLAN assignment feature on interface `port1.0.2`, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth dynamic-vlan-creation
```

Validation Commands

show dot1x
show dot1x interface
show running-config

Related Commands

auth host-mode

auth guest-vlan

This command enables and configures the Guest VLAN feature on the interface specified by associating a Guest VLAN with an interface. This command does not start authentication. The supplicant's (client device's) traffic is associated with the native VLAN of the interface if its not already associated with another VLAN. The routing option enables routing from the Guest VLAN to another VLAN, so the switch can lease DHCP addresses and accept access to a limited network.

The no variant of this command disables the guest vlan feature on the interface specified.

Syntax

```
auth guest-vlan <1-4094> [routing]
no auth guest-vlan [routing]
```

Parameter	Description
<1-4094>	VLAN ID (VID).
`routing`	Enables routing from the Guest VLAN to other VLANs.

Default The Guest VLAN authentication feature is disabled by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage The Guest VLAN feature may be used by supplicants (client devices) that have not attempted authentication, or have failed the authentication process. Note that if a port is in multi-supplicant mode with per-port dynamic VLAN configuration, after the first successful authentication, subsequent hosts cannot use the guest VLAN due to the change in VLAN ID. This may be avoided by using per-user dynamic VLAN assignment.

When using the Guest VLAN feature with the multi-host mode, a number of supplicants can communicate via a guest VLAN before authentication. A supplicant's traffic is associated with the native VLAN of the specified switch port. The supplicant must belong to a VLAN before traffic from the supplicant can be associated.

Note that you must first define the VLAN with the vlan command that you will assign as a guest VLAN using this command. Also note that 802.1X must first be enabled on the port.

Guest VLAN authentication cannot be enabled if DHCP snooping is enabled (service dhcp-snooping command on page 78.24), and vice versa.

The Guest VLAN feature in previous releases had some limitations that have been removed. Until this release the Guest VLAN feature could not lease the IP address to the supplicant using DHCP Server or DHCP Relay features unless Web authentication was also applied. When using NAP authentication, the supplicant should have been able to log on to a domain controller to gain certification, but the Guest VLAN would not accept access to another VLAN.

The Guest VLAN routing mode in this release overcomes these issues. With the Guest VLAN routing mode, the switch can lease DHCP addresses and accept access to a limited network.

See the section "Guest VLAN Enhancements" on page 64.10 for further overview information about the enhancements to the Guest VLAN feature.

See the section "Limitations on allowed feature combinations" on page 64.12 for information about restrictions regarding combinations of authentication enhancements working together.

Examples

To define `vlan100` and assign the guest VLAN feature to `vlan100` on interface `port1.0.2`, and enable routing from the guest vlan to other VLANs, use the following commands:

```
awplus# configure terminal
awplus(config)# vlan database
awplus(config-vlan)# vlan 100
awplus(config-vlan)# exit
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x port-control auto
awplus(config-if)# auth guest-vlan 100 routing
```

To disable the guest vlan feature on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth guest-vlan
```

Validation Commands

show dot1x
show dot1x interface
show running-config

Related Commands

dot1x port-control
vlan

auth host-mode

This command selects host mode on the interface. Multi-host is an extension to IEEE802.1X.

Use the no variant of this command to set host mode to the default setting (single host).

Syntax

```
auth host-mode {single-host|multi-host|multi-supplicant}
no auth host-mode
```

Parameter	Description
`single-host`	Single host mode.
`multi-host`	Multi host mode.
`multi-supplicant`	Multi supplicant (client device) mode.

Default The default host mode for port authentication is for a single host.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To set the host mode to multi-supplicant on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth host-mode multi-supplicant
```

To set the host mode to default (single host) on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth host-mode
```

Validation Commands

show dot1x
show dot1x interface
show running-config

auth log

Use this command to configure the types of authentication feature log messages that are output to the log file.

Use the no variant of this command to remove either specified types or all types of authentication feature log messages that are output to the log file.

Syntax

```
auth log {dot1x|auth-mac|auth-web} {success|failure|logoff|all}
no auth log {do1x|auth-mac|auth-web} {success|failure|logoff|all}
```

Parameter	Description
`dot1x`	Specify only 802.1X authentication log messages are output to the log file.
`auth-mac`	Specify only MAC authentication log messages are output to the log file.
`auth-web`	Specify only Web authentication log messages are output to the log file.
`success`	Specify only successful authentication log messages are output to the log file.
`failure`	Specify only authentication failure log messages are output to the log file.
`logoff`	Specify only authentication logoff messages are output to the log file. Note that link down, age out and expired ping polling messages will be included.
`all`	Specify all types of authentication log messages are output to the log file Note that this is the default behavior for the authentication logging feature.

Default All types of authentication log messages are output to the log file by default.

Mode Interface Configuration

Examples To configure the logging of MAC authentication failures to the log file for supplicants (client devices) connected to interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth log auth-mac failure
```

To configure the logging of all types of authentication log messages to the log file for supplicants (client devices) connected to interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth log all
```

Validation Commands show running-config

auth max-supplicant

This command sets the maximum number of supplicants (client devices) on the interface that can be authenticated. After this value is exceeded supplicants are not authenticated.

The no variant of this command resets the maximum supplicant number to the default (1024).

Syntax

```
auth max-supplicant <2-1024>
no auth max-supplicant
```

Parameter	Description
<2-1024>	Limit number.

Default The max supplicant of port authentication is 1024.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To set the maximum number of supplicants to `10` on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth max-supplicant 10
```

To reset the maximum number of supplicant to default on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth max-supplicant
```

Validation Commands

show dot1x
show dot1x interface
show running-config

auth reauthentication

This command enables re-authentication on the interface specified in the Interface mode, which may be a static channel group (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

Use the no variant of this command to disables reauthentication on the interface.

Syntax

```
auth reauthentication
no auth reauthentication
```

Default Reauthentication of port authentication is disabled by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To enable reauthentication on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth reauthentication
```

Validation Commands

show dot1x
show dot1x interface
show running-config

auth roaming disconnected

This command enables the roaming authentication feature on an authenticated interface that is link down. A supplicant (a client device) is not reauthenticated when moved between authenticated interfaces, providing both interfaces have the roaming authentication feature enabled before the supplicant is moved.

Use the auth roaming enable command before using this command. The auth roaming disconnected command on its own will have no effect on the operation of the switch. This command will only come into effect once the base Roaming Authentication feature is enabled, using the auth roaming enable command.

The no variant of this command disables the roaming authentication feature on an interface, and forces a supplicant to be reauthenticated when moving between interfaces.

See "Roaming Authentication" on page 64.4 for further information about this feature.

Syntax

```
auth roaming disconnected

no auth roaming disconnected
```

Default The roaming authentication `disconnected` feature is disabled by default on an interface. Authentication status for a roaming supplicant is deleted by default when an interface goes down.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage This command allows a supplicant to move to another authenticating interface without reauthentication, if the link is down for the interface that the supplicant is moved from.

Note that 802.1X port authentication, or MAC authentication, or Web Authentication must first be enabled on an interface to use this feature. The port that the supplicant is moving to must have the same authentication configuration as the port the supplicant is moving from.

Configure auth roaming enable on an interface before configuring auth roaming disconnected if you require auth roaming disconnected configured on an interface for a roaming supplicant.

Roaming authentication cannot be enabled if DHCP snooping is enabled (service dhcp-snooping command on page 78.24), and vice versa.

Examples To enable roaming authentication `disconnected` feature for `port1.0.2`, after enabling 802.1x authentication and enabling roaming authentication `enable`, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# dot1x port-control auto
awplus(config-if)# auth roaming enable
awplus(config-if)# auth roaming disconnected
```

To disable roaming authentication disconnected feature for `port1.0.2`, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth roaming disconnected
```

Validation Commands

show running-config

Related Commands

auth-mac enable
auth roaming enable
auth-web enable
dot1x port-control
show auth-mac interface
show auth-web interface
show dot1x interface

auth roaming enable

This command enables the roaming authentication feature on an authenticated interface that is link up. A supplicant (a client device) is not reauthenticated when moved between authenticated interfaces, providing both interfaces have the roaming authentication feature enabled before the supplicant is moved.

Use the auth roaming enable command before using auth roaming disconnected command. The auth roaming disconnected command on its own will have no effect on the operation of the switch. This command will only come into effect once the base Roaming Authentication feature is enabled, using the auth roaming enable command.

The no variant of this command disables the roaming authentication feature on an interface, and forces a supplicant to be reauthenticated when moving between interfaces.

See "Roaming Authentication" on page 64.4 for further information about this feature.

Syntax

```
auth roaming enable
no auth roaming enable
```

Default The roaming authentication enable feature is disabled by default on an interface. Authentication status for a roaming supplicant is deleted by default when an interface goes down.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage This command allows a supplicant to move to another authenticating interface without reauthentication, providing the link is up for the interface that the supplicant is moved from.

Note that 802.1X port authentication, or MAC authentication, or Web Authentication must first be enabled on an interface to use this feature. The port that the supplicant is moving to must have the same authentication configuration as the port the supplicant is moving from.

Configure auth roaming enable on an interface before configuring auth roaming disconnected if you require auth roaming disconnected configured on an interface for a roaming supplicant.

Roaming authentication cannot be enabled if DHCP snooping is enabled (service dhcp-snooping command on page 78.24), and vice versa.

Examples To enable the roaming authentication enable feature for interface `port1.0.4`, after enabling 802.1x authentication, since an authentication method is required, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.4
awplus(config-if)# dot1x port-control auto
awplus(config-if)# auth roaming enable
```

To disable roaming authentication enable for `port1.0.4`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.4
awplus(config-if)# no auth roaming enable
```

Validation Commands

show running-config

Related Commands

dot1x port-control
show auth-mac interface
show auth-web interface
show dot1x interface

auth supplicant-mac

This command adds a supplicant (client device) mac address on a given interface with the parameters as specified in the table below.

Use the no variant of this command to delete the supplicant MAC address added by the auth supplicant-mac command, and resets to the default for the supplicant parameter.

Syntax

```
auth supplicant <mac-addr>
   [max-reauth-req <1-10>]
   [port-control {auto | force-authorized | force-unauthorized}]
   [quiet-period <1-65535>]
   [reauth-period <1-4294967295>]
   [supp-timeout <1-65535>]
   [server-timeout <1-65535>][reauthentication]

no auth supplicant-mac <macadd> [reauthentication]
```

Parameter	Description
<mac-addr>	MAC (hardware) address of the Supplicant entry in HHHH.HHHH.HHHH MAC address hexadecimal format.
`port-control`	Port control commands.
`auto`	Allow port client to negotiate authentication.
`force-authorized`	Force port state to authorized.
`force-unauthorized`	Force port state to unauthorized.
`quiet-period`	Quiet period in the HELD state (default 60 seconds).
<1-65535>	Seconds for quiet period.
`reauth-period`	Seconds between reauthorization attempts (default 3600 seconds).
<1-4294967295>	Seconds for reauthorization attempts (reauth-period).
`supp-timeout`	Supplicant response timeout (default 30 seconds).
<1-65535>	Seconds for supplicant response timeout.
`server-timeout`	Authentication server response timeout (default 30 seconds).
<1-65535>	Seconds for authentication server response timeout.
`reauthentication`	Enable reauthentication on a port.
`max-reauth-req`	No of reauthentication attempts before becoming unauthorized (default 2).
<1-10>	Count of reauthentication attempts.

Default No supplicant MAC address for port authentication exists by default until first created with the auth supplicant-mac command. The defaults for parameters applied are as shown in the table.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To add the supplicant MAC address `0009.41A4.5943` to force authorized port control for interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth supplicant-mac 0009.41A4.5943 port-
control force-authorized
```

To delete the supplicant MAC address `0009.41A4.5943` for interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth supplicant-mac 0009.41A4.5943
```

To reset reauthentication to disable for the supplicant MAC address `0009.41A4.5943`, for interface `port1.0.2` use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth supplicant-mac 0009.41A4.5943
reauthentication
```

Validation Commands show dot1x
show dot1x interface
show running-config

auth timeout quiet-period

This command sets the time period for which the authentication request is not accepted on a given interface, after the authentication request has failed an authentication.

Use the no variant of this command to reset quiet period to the default (60 seconds).

Syntax

```
auth timeout quiet-period <1-65535>
no auth timeout quiet-period
```

Parameter	Description
<1-65535>	Seconds.

Default The quiet period of port authentication is 60 seconds.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To set the quiet period to `10` for interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth timeout quiet-period 10
```

To reset the quiet period to the default (60 seconds) for interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth timeout quiet-period
```

auth timeout reauth-period

This command sets the timer for reauthentication on a given interface. The re-authentication for the supplicant (client device) is executed at this timeout. The timeout is only applied if the auth reauthentication command is applied.

Use the no variant of this command to reset the reauth-period parameter to the default (3600 seconds).

Syntax

```
auth timeout reauth-period <1-4294967295>
no auth timeout reauth-period
```

Parameter	Description
<1-4294967295>	Seconds.

Default The default reauthentication period for port authentication is 3600 seconds, when reauthentication is enabled on the port.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To set the reauthentication period to 1 day for interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth timeout reauth-period 86400
```

To reset the reauthentication period to the default (3600 seconds) for interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth timeout reauth-period
```

Validation Commands
show dot1x
show dot1x interface
show running-config

Related Commands auth reauthentication

auth timeout server-timeout

This command sets the timeout for the waiting response from the RADIUS server on a given interface.

The no variant of this command resets the server-timeout to the default (30 seconds).

Syntax

```
auth timeout server-timeout <1-65535>
no auth timeout server-timeout
```

Parameter	Description
<1-65535>	Seconds.

Default The server timeout for port authentication is 30 seconds.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To set the server timeout to 120 seconds for interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth timeout server-timeout 120
```

To set the server timeout to the default (30 seconds) for interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth timeout server-timeout
```

Validation Commands

show dot1x
show dot1x interface
show running-config

auth timeout supp-timeout

This command sets the timeout of the waiting response from the supplicant (client device) on a given interface.

The no variant of this command resets the supplicant timeout to the default (30 seconds).

Syntax

```
auth timeout supp-timeout <1-65535>
no auth timeout supp-timeout
```

Parameter	Description
<1-65535>	Seconds.

Default The supplicant timeout of port authentication is 30 seconds.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To set the server timeout to 2 seconds for interface port1.0.2, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth timeout supp-timeout 2
```

To reset the server timeout to the default (30 seconds) for interface port1.0.2, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth timeout supp-timeout
```

Validation Commands

show dot1x
show dot1x interface
show running-config

auth-mac enable

This command enables MAC based authentication on the interface specified in the Interface command mode.

Use the no variant of this command to disable MAC based authentication on an interface.

Syntax

```
auth-mac enable
no auth-mac enable
```

Default MAC authentication is disabled by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Usage Enabling spanning-tree edgeport on ports after enabling MAC based authentication avoids unnecessary re-authentication when the port state changes, which does not happen when spanning tree edgeport is enabled. Note that re-authentication is correct behavior without spanning-tree edgeport enabled.

Applying switchport mode access on ports is also good practice to set the ports to access mode with ingress filtering turned on, whenever ports for MAC authentication are in a VLAN.

Examples To enable MAC authentication on interface `port1.0.2` and enable spanning tree edgeport to avoid unnecessary re-authentication, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth-mac enable
awplus(config-if)# spanning-tree edgeport
awplus(config-if)# switchport mode access
```

To disable MAC authentication on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth-mac enable
```

Validation Commands
show auth-mac
show auth-mac interface
show running-config

switchport mode access

auth-mac method

This command sets the type of authentication method for MAC authentication that is used with RADIUS on the interface specified in the Interface command mode.

The no variant of this command resets the authentication method used to the default method (PAP) as the RADIUS authentication method used by the MAC authentication.

Syntax

```
auth-mac method [eap-md5|pap]
no auth-mac method
```

Parameter	Description
eap-md5	Enable EAP-MD5 of authentication method.
pap	Enable PAP of authentication method.

Default The mac authentication method is PAP.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To set the MAC authentication method to `pap` on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth-mac method pap
```

To set the MAC authentication method to the default on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth-mac method
```

Validation Commands

show auth-mac
show auth-mac interface
show running-config

auth-mac reauth-relearning

This command sets the MAC address learning of the supplicant (client device) to re-learning for re-authentication on the interface specified in the Interface command mode.

Use the no variant of this command to disable the auth-mac re-learning option.

Syntax

```
auth-mac reauth-relearning
no auth-mac reauth-relearning
```

Default Re-learning for port authentication is disabled by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To enable the re-authentication re-learning feature on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth-mac reauth-relearning
```

To disable the re-authentication re-learning feature on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth-mac reauth-relearning
```

Validation Commands

show auth-mac
show auth-mac interface
show running-config

auth-web enable

This command enables Web-based authentication in Interface mode on the interface specified.

Use the no variant of this command to disable Web-based authentication on an interface.

Syntax

```
auth-web enable
no auth-web enable
```

Default Web authentication is disabled by default.

Mode Interface Configuration for a static channel or a switch port.

Usage Web-based authentication cannot be enabled if DHCP snooping is enabled (service dhcp-snooping command on page 78.24), and vice versa.

Examples To enable Web authentication on static-channel-group 2, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# static-channel-group 2
awplus(config-if)# exit
awplus(config)# interface sa2
awplus(config-if)# auth-web enable
```

To disable Web authentication on static-channel-group 2, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# static-channel-group 2
awplus(config-if)# exit
awplus(config)# interface sa2
awplus(config-if)# no auth-web enable
```

Validation Commands
show auth-web
show auth-web interface
show running-config

Related Commands
aaa accounting auth-web default
aaa authentication auth-web

auth-web forward

This command enables the web authentication packet forwarding feature on the interface specified. This command also enables ARP forwarding, and adds forwarded packets to the tcp or udp port number specified.

The no variant of this command disables or deletes the packet forwarding feature on the interface.

Syntax

```
auth-web forward {arp|dhcp|dns|tcp <1-65535>|udp <1-65535>}
no auth-web forward [arp|dhcp|dns|tcp <1-65535>|udp <1-65535>]
```

Parameter	Description
arp	Enable forwarding of ARP.
dhcp	Enable forwarding of DHCP (67/udp).
dns	Enable forwarding of DNS (53/udp).
tcp	Enable forwarding of TCP specified port number.
<1-65535>	TCP Port number.
udp	Enable forwarding of UDP specified port number.
<1-65535>	UDP Port number.

Default Packet forwarding for port authentication is disabled by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To enable the arp forwarding feature on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth-web forward arp
```

To add the tcp forwarding port 137 on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth-web forward tcp 137
```

To disable the ARP forwarding feature on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth-web forward arp
```

To delete the tcp forwarding port 137 on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth-web forward tcp 137
```

To delete the all of tcp forwarding on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth-web forward tcp
```

Validation Commands

show auth-web
show auth-web interface
show running-config

auth-web max-auth-fail

This command sets the number of authentication failures allowed before rejecting further authentication requests. When the supplicant (client device) fails more than has been set to the maximum number of authentication failures then login requests are refused during the quiet period.

The no variant of this command resets the maximum number of authentication failures to the default (3 authentication failures).

Syntax

```
auth-web max-auth-fail <0-10>
no auth-web max-auth-fail
```

Parameter	Description
<0-10>	Lock count specified.

Default The max-auth-fail lock counter is set to 3 authentication failures by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Examples To set the lock count to `5` on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth-web max-auth-fail 5
```

To set the lock count to the default on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no auth-web max-auth-fail
```

Validation Commands show auth-web
show auth-web interface
show running-config

Related Commands auth timeout quiet-period

auth-web method

This command sets the authentication method of WEB authentication that is used with RADIUS on the interface specified.

The no variant of this command sets the authentication method to PAP for the interface specified when Web authentication is also used with the RADIUS authentication method.

Syntax

```
auth-web method {eap-md5|pap}
no auth-web method
```

Parameter	Description
eap-md5	Enable EAP-MD5 as the authentication method.
pap	Enable PAP as the authentication method.

Default The web authentication method is set to PAP by default.

Mode Interface Configuration for a static channel, a dynamic (LACP) channel group, or a switch port.

Example To set the web authentication method to eap-md5 on interface `port1.0.2`, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# auth-web method eap-md5
```

Validation Commands

show auth-web
show auth-web interface
show running-config

auth-web-server dhcp ipaddress

Use this command to assign an IP address and enable the DHCP service on the web authentication server for supplicants (client devices).

Use the no variant of this command to remove an IP address and disable the DHCP service on the web authentication server for supplicants.

Syntax

```
auth-web-server dhcp ipaddress <ip-address/prefix-length>
no auth-web-server dhcp ipaddress
```

Parameter	Description
<ip-addr/prefix-length>	The IPv4 address and prefix length assigned for the DHCP service on the web authentication server for supplicants.

Default No IP address for the web authentication server is set by default.

Mode Global Configuration

Usage See the section "DHCP Server for Web-authentication" on page 64.9 in Chapter 64, Authentication Introduction and Configuration for further overview information about the Web-authentication enhancements, allowing Web-authentication to work as seamlessly as 802.1X authentication.

See the section "Limitations on allowed feature combinations" on page 64.12 for information about restrictions regarding combinations of authentication enhancements working together.

Examples To assign the IP address `10.0.0.1` to the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server dhcp ip address 10.0.0.1/8
```

To remove an IP address on the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server dhcp ip address
```

Validation Commands show running-config

Related Commands show auth-web-server
auth-web-server dhcp lease

auth-web-server dhcp lease

Use this command to set the DHCP lease time for supplicants (client devices) using the DHCP service on the web authentication server.

Use the no variant of this command to reset to the default DHCP lease time for supplicants using the DHCP service on the web authentication server.

Syntax

```
auth-web-server dhcp lease <20-60>
no auth-web-server dhcp lease
```

Parameter	Description
<20-60>	DHCP lease time for supplicants using the DHCP service on the web authentication server in seconds.

Default The default DHCP lease time for supplicants using the DHCP service on the web authentication server is set to 30 seconds.

Mode Global Configuration

Usage See the section "DHCP Server for Web-authentication" on page 64.9 in Chapter 64, Authentication Introduction and Configuration for further overview information about the Web-authentication enhancements, allowing Web-authentication to work as seamlessly as 802.1X authentication.

See the section "Limitations on allowed feature combinations" on page 64.12 for information about restrictions regarding combinations of authentication enhancements working together.

Examples To set the DHCP lease time to 1 minute for supplicants using the DHCP service on the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server dhcp lease 60
```

To reset the DHCP lease time to the default setting (30 seconds) for supplicants using the DHCP service on the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server dhcp lease
```

Validation Commands show running-config

Related Commands show auth-web-server
auth-web-server dhcp ipaddress

auth-web-server http-redirect

This command enables the HTTP redirect feature on every interface on which web-based port authentication is enabled. When the HTTP redirect feature is enabled, any HTTP request received on an unauthorized interface is redirected to the web authentication server automatically.

Use the no variant of this command to disable the HTTP redirect feature.

Syntax

```
auth-web-server http-redirect
no auth-web-server http-redirect
```

Default The HTTP redirect feature is enabled by default.

Mode Global Configuration

Examples To disable the HTTP redirect feature, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server http-redirect
```

To re-enable the HTTP redirect feature, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server http-redirect
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server ipaddress

This command sets the IP address for the web authentication server.

Use the no variant of this command to delete the IP address for the web authentication server.

Syntax

```
auth-web-server ipaddress <ip-address>
no auth-web-server ipaddress
```

Parameter	Description
<ip-address>	Web authentication server dotted decimal IP address in A.B.C.D format.

Default The web authentication server address on the system is not set by default.

Mode Global Configuration

Examples To set the IP address `10.0.0.1` to the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server ipaddress 10.0.0.1
```

To delete the IP address from the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server ipaddress
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server mode

Use this command with required keyword to configure an intercept mode (from the intercept, none, or promiscuous modes available) on the web authentication server for supplicants (client devices). The intercept modes available affect the interception of clients' ARPs and the proxy DNS response when using Web-authentication. These enhancements ensure that Web-authentication will proceed smoothly irrespective of the IP configuration on the client PC.

Use the no variant of this command to disable the intercept mode (either the intercept, none, or promiscuous intercept modes) configured on the web authentication server for supplicants.

Syntax

```
auth-web-server mode {intercept|none|promiscuous}

no auth-web-server mode {intercept|promiscuous}
```

Parameter	Description
`intercept`	Selecting this parameter results in web authentication server on the switch intercepting and replying to ARP and DNS messages from the same interface and IP address.
`none`	Selecting this parameter disables the intercept mode on the web authentication server. No ARP and DNS messages are intercepted and replied to from the switch from any interfaces or from any IP addresses.
`promiscuous`	Selecting this parameter results in the web authentication server on the switch intercepting and replying to any ARP or DNS messages from any IP address.

Default Intercept mode on the web authentication server is set to none by default.

Mode Global Configuration

Usage See the section "Web-authentication Enhancements" on page 64.9 in Chapter 64, Authentication Introduction and Configuration for further overview information about the Web-authentication enhancements, allowing Web-authentication to work as seamlessly as 802.1X authentication.

See the sub-sections "Interception of clients' ARPs" on page 64.9 and "Proxy DNS response" on page 64.10for an details of the associated usage of the available intercept modes.

See the section "Limitations on allowed feature combinations" on page 64.12 for information about restrictions regarding combinations of authentication enhancements working together.

Examples To enable the intercept mode on the web authentication server, resulting in the switch intercepting and replying to ARP and DNS messages from the same interface and IP address, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server mode intercept
```

To disable the intercept mode on the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server mode intercept
```

To reset the intercept mode to the default setting of none on the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server mode none
```

To enable the promiscuous mode on the web authentication server, resulting in the switch intercepting and replying to any ARP or DNS messages from any IP address, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server mode promiscuous
```

To disable the promiscuous mode on the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server mode promiscuous
```

Validation Commands show running-config

Related Commands show auth-web-server

auth-web-server ping-poll enable

This command enables the ping polling to the supplicant (client device) that is authenticated by web authentication.

The no variant of this command disables the ping polling to the supplicant that is authenticated by web authentication.

Syntax

```
auth-web-server ping-poll enable
no auth-web-server ping-poll enable
```

Default The ping polling feature for web authentication is disabled by default.

Mode Global Configuration

Examples To enable the ping polling feature for web authentication, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server ping-poll enable
```

To disable the ping polling feature for web authentication, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server ping-poll enable
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server ping-poll failcount

This command sets a fail count for the ping polling feature when used with web authentication. The failcount parameter specifies the number of unanswered pings. A supplicant (client device) is logged off when the number of unanswered pings are greater than the failcount set with this command.

Use the no variant of this command to resets the fail count for the ping polling feature to the default (5 pings).

Syntax

```
auth-web-server ping-poll failcount <1-100>
no auth-web-server ping-poll failcount
```

Parameter	Description
<1-100>	Count.

Default The default failcount for ping polling is 5 pings.

Mode Global Configuration

Examples To set the failcount of ping polling to `10` pings, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server ping-poll failcount 10
```

To set the failcount of ping polling to default, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server ping-poll failcount
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server ping-poll interval

This command is used to change the ping poll interval. The interval specifies the time period between pings when the supplicant (client device) is reachable.

Use the no variant of this command to reset to the default period for ping polling (30 seconds).

Syntax

```
auth-web-server ping-poll interval <1-65535>
no auth-web-server ping-poll interval
```

Parameter	Description
<1-65535>	Seconds.

Default The interval for ping polling is 30 seconds by default.

Mode Global Configuration

Examples To set the interval of ping polling to `60` seconds, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server ping-poll interval 60
```

To set the interval of ping polling to the default (30 seconds), use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server ping-poll interval
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server ping-poll reauth-timer-refresh

This command modifies the reauth-timer-refresh parameter for the web-authentication feature. The reauth-timer-refresh parameter specifies whether a re-authentication timer is reset and when the response from a supplicant (a client device) is received.

Use the no variant of this command to reset the reauth-timer-refresh parameter to the default setting (disabled).

Syntax

```
auth-web-server ping-poll reauth-timer-refresh
no auth-web-server ping-poll reauth-timer-refresh
```

Default The `reauth-timer-refresh` parameter is disabled by default.

Mode Global Configuration

Examples To enable the `reauth-timer-refresh` timer, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server ping-poll reauth-timer-refresh
```

To disable the `reauth-timer-refresh` timer, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server ping-poll reauth-timer-
refresh
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server ping-poll timeout

This command modifies the ping poll timeout parameter for the web authentication feature. The timeout parameter specifies the time in seconds to wait for a response to a ping packet.

Use the no variant of this command to reset the timeout of ping polling to the default (1 second).

Syntax

```
auth-web-server ping-poll timeout <1-30>
no auth-web-server ping-poll timeout
```

Parameter	Description
<1-30>	Seconds.

Default The default timeout for ping polling is 1 second.

Mode Global Configuration

Examples To set the timeout of ping polling to 2 seconds, use the command:

```
awplus# configure terminal
awplus(config)# auth-web-server ping-poll timeout 2
```

To set the timeout of ping polling to the default (1 second), use the command:

```
awplus# configure terminal
awplus(config)# no auth-web-server ping-poll timeout
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server port

This command sets the HTTP port number for the web authentication server.

Use the no variant of this command to reset the HTTP port number to the default (80).

Syntax

```
auth-web-server port <port-number>
no auth-web-server port
```

Parameter	Description
<port-number>	Set the local web authentication server port within the TCP port number range 1 to 65535.

Default The web authentication server HTTP port number is set to 80 by default.

Mode Global Configuration

Examples To set the HTTP port number `8080` for the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server port 8080
```

To reset to the default HTTP port number `80` for the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server port
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server redirect-url

This command sets a URL for supplicant (client device) authentication. When a supplicant is authorized it will be automatically redirected to the specified URL. Note that if the http redirect feature is used then this command is ignored.

Use the no variant of this command to delete the URL string set previously.

Syntax

```
auth-web-server redirect-url <url>
no auth-web-server redirect-url
```

Parameter	Description
<url>	URL (hostname or dotted IP notation).

Default The redirect URL for the web authentication server feature is not set by default (null).

Mode Global Configuration

Examples To enable and set redirect a URL string `www.alliedtelesis.com` for the web authentication server, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server redirect-url
                http://www.alliedtelesis.com
```

To delete a redirect URL string, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server redirect-url
```

Validation Commands
show auth-web
show auth-web-server
show running-config

Related Commands auth-web-server http-redirect

auth-web-server session-keep

This command enables the session-keep feature to jump to the original URL after being authorized by web authentication.

Use the no variant of this command to disable the session keep feature.

Syntax

```
auth-web-server session-keep
no auth-web-server session-keep
```

Default The session-keep feature is disabled by default.

Mode Global Configuration

Examples To enable the session-keep feature, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server session-keep
```

To disable the session-keep feature, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server session-keep
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server ssl

This command enables HTTPS functionality for the web authentication server feature.

Use the no variant of this command to disable HTTPS functionality for the web authentication server.

Syntax

```
auth-web-server ssl
no auth-web-server ssl
```

Default HTTPS functionality for the web authentication server feature is disabled by default.

Mode Global Configuration

Examples To enable HTTPS functionality for the web authentication server feature, use the following commands:

```
awplus# configure terminal
awplus(config)# auth-web-server ssl
```

To disable HTTPS functionality for the web authentication server feature, use the following commands:

```
awplus# configure terminal
awplus(config)# no auth-web-server ssl
```

Validation Commands

show auth-web
show auth-web-server
show running-config

auth-web-server sslport

This command sets the HTTPS port number for the web authentication server feature.

Use the no variant of this command to reset the HTTPS port number to the default port number (443) for the web authentication server feature.

Syntax

```
auth-web-server sslport <1-65535>
no auth-web-server sslport
```

Parameter	Description
<1-65535>	Set the local web authentication server port within the TCP port number range 1to 65535.

Default The HTTPS port number for the web authentication server feature is set to 443 by default.

Mode Global Configuration

Examples To set the HTTPS port number to 4433 for the web authentication server, use the command:

```
awplus# configure terminal
awplus(config)# auth-web-server sslport 4433
```

To reset the HTTPS port number for the web authentication server to the default (443), use the command:

```
awplus# configure terminal
awplus(config)# no auth-web-server sslport
```

Validation Commands

show auth-web
show auth-web-server
show running-config

copy web-auth-https-file

Use this command to download the SSL server certificate for web-based authentication. The file must be in PEM (Privacy Enhanced Mail) format, and contain the private key and the server certificate.

Syntax

```
copy <filename> web-auth-https-file
```

Parameter	Description
<filename>	The URL of the server certificate file.

Mode Privileged Exec

Example To download the server certificate file `veriSign_cert.pem` from the TFTP server directory `server`, use the command:

```
awplus# copy tftp://server/veriSign_cert.pem web-auth-https-
file
```

Related Commands

auth-web-server ssl
erase web-auth-https-file
show auth-web-server

erase web-auth-https-file

Use this command to remove the SSL server certificate for web-based authentication.

Syntax `erase web-auth-https-file`

Use this command to remove the SSL server certificate for web-based authentication.

Mode Privileged Exec

Example To remove the SSL server certificate file for web-based authentication use the command:

```
awplus# erase web-auth-https-file
```

Related Commands auth-web-server ssl
copy web-auth-https-file
show auth-web-server

show auth-mac

This command shows authentication information for MAC-based authentication.

Syntax

```
show auth-mac [all]
```

Parameter	Description
`all`	Display all authentication information for each interface available on the switch.

Mode Privileged Exec

Example To display all MAC based authentication information, enter the command:

```
awplus# show auth-mac all
```

Output Figure 65-1: Example output from the **show auth-mac** command

```
802.1X Port-Based Authentication Disabled
MAC-based Port Authentication Enabled
WEB-based Port Authentication Disabled
```

Related Commands

show dot1x
show auth-web

show auth-mac diagnostics

This command shows MAC authentication diagnostics, optionally for the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

If no interface is specified then authentication diagnostics are shown for all interfaces.

Syntax

```
show auth-mac diagnostics [interface <interface-list>]
```

Parameter	Description
`interface`	Specify an interface to show
`<interface-list>`	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example To display authentication diagnostics for `port1.0.12`, enter the command:

```
awplus# show auth-mac diagnostics interface port1.0.12
```

Output Figure 65-2: Example output from the **show auth-mac diagnostics** command

```
Authentication Diagnostics for interface port1.0.12
    Supplicant address: 00d0.59ab.7037
        authEnterConnecting: 2
        authEaplogoffWhileConnecting: 1
        authEnterAuthenticating: 2
        authSuccessWhileAuthenticating: 1
        authTimeoutWhileAuthenticating: 1
        authFailWhileAuthenticating: 0
        authEapstartWhileAuthenticating: 0
        authEaplogoggWhileAuthenticating: 0
        authReauthsWhileAuthenticated: 0
        authEapstartWhileAuthenticated: 0
        authEaplogoffWhileAuthenticated: 0
        BackendResponses: 2
        BackendAccessChallenges: 1
        BackendOtherrequestToSupplicant: 3
        BackendAuthSuccess: 1
```

show auth-mac interface

This command shows the status for MAC based authentication on the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

Use the optional diagnostics parameter to show authentication diagnostics for the specified interface. Use the optional sessionstatistics parameter to show authentication session statistics for the specified interface. Use the optional statistics parameter to show authentication diagnostics for the specified interface. Use the optional supplicant (client device) parameter to show the supplicant state for the specified interface.

Syntax

```
show auth-mac interface <interface-list>
   [diagnostics|sessionstatistics|statistics|supplicant [brief]]
```

Parameter	Description
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.
`diagnostics`	Diagnostics.
`sessionstatistics`	Session statistics.
`statistics`	Statistics.
`supplicant`	Supplicant (client device).
`brief`	Brief summary of supplicant state.

Mode Privileged Exec

Examples To display MAC based authentication status for `port1.0.12`, enter the command:

```
awplus# show auth-mac interface port1.0.2
```

```
% Port-Control not configured on port1.0.2
```

To display MAC authentication diagnostics for `port1.0.12`, enter the command:

```
awplus# show auth-mac interface port1.0.12 diagnostics
```

```
Authentication Diagnostics for interface port1.0.2
    Supplicant address: 00d0.59ab.7037
        authEnterConnecting: 2
        authEaplogoffWhileConnecting: 1
        authEnterAuthenticating: 2
        authSuccessWhileAuthenticating: 1
        authTimeoutWhileAuthenticating: 1
        authFailWhileAuthenticating: 0
        authEapstartWhileAuthenticating: 0
        authEaplogoggWhileAuthenticating: 0
        authReauthsWhileAuthenticated: 0
        authEapstartWhileAuthenticated: 0
        authEaplogoffWhileAuthenticated: 0
        BackendResponses: 2
        BackendAccessChallenges: 1
        BackendOtherrequestToSupplicant: 3
        BackendAuthSuccess: 1
```

To display authentication session statistics for `port1.0.12`, enter the command:

```
awplus# show auth-mac interface port1.0.12 sessionstatistics
```

```
Authentication session statistics for interface port1.0.12
    session user name: manager
        session authentication method: Remote server
        session time: 19440 secs
        session terminat cause: Not terminated yet
```

To display MAC authentication statistics for `port1.0.12`, enter the command:

```
awplus# show auth-mac interface port1.0.12 statistics
```

To display the MAC authenticated supplicant on interface `port1.0.12`, enter the command:

```
awplus# show auth-mac interface port1.0.12 supplicant
```

Related Commands

show auth-web diagnostics
show dot1x sessionstatistics
show dot1x statistics interface
show dot1x supplicant interface

show auth-mac sessionstatistics

This command shows authentication session statistics for the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

Syntax `show auth-mac sessionstatistics [interface <interface-list>]`

Parameter	Description
`interface`	Specify an interface to show.
`<interface-list>`	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example To display output displaying MAC authentication session statistics for `port1.0.12`, enter the command:

```
awplus# show auth-mac sessionstatistics interface port1.0.12
```

Output Figure 65-3: Example output from the **show auth-mac sessionstatistics** command

```
Authentication session statistics for interface port1.0.12
    session user name: manager
        session authentication method: Remote server
        session time: 19440 secs
        session terminat cause: Not terminated yet
```

show auth-mac statistics interface

This command shows the authentication statistics for the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

Syntax

```
show auth-mac statistics [interface <interface-list>]
```

Parameter	Description
`interface`	Specify ports to show.
`<interface-list>`	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example To display MAC authentication statistics for `port1.0.12`, enter the command:

```
awplus# show auth-mac statistics interface port1.0.12
```

Related Commands show dot1x interface

show auth-mac supplicant

This command shows the supplicant (client device) state when MAC authentication is configured for the switch. This command shows a summary when the optional brief parameter is used.

Syntax `show auth-mac supplicant [<macadd>] [brief]`

Parameter	Description
<macadd>	Mac (hardware) address of the Supplicant Entry format is HHHH.HHHH.HHHH (hexadecimal).
`brief`	Brief summary of the Supplicant state.

Mode Privileged Exec

Example To display the MAC authenticated supplicant for MAC address `00d0.59ab.7037`, enter the command:

```
awplus# show auth-mac supplicant 00d0.59ab.7037
```

show auth-mac supplicant interface

This command shows the supplicant (client device) state for the MAC authenticated interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port. This command shows a summary when the optional brief parameter is used.

Syntax

```
show auth-mac supplicant [interface <interface-list>] [brief]
```

Parameter	Description
`interface`	Specify ports to show.
`<interface-list>`	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.
`brief`	Brief summary of the supplicant state.

Mode Privileged Exec

Examples To display the MAC authenticated supplicant on the interface `port1.0.12`, enter the command:

```
awplus# show auth-mac supplicant interface port1.0.12
```

To display brief summary output for the MAC authenticated supplicant, enter the command:

```
awplus# show auth-mac supplicant brief
```

show auth-web

This command shows authentication information for Web-based authentication.

Syntax

```
show auth-web [all]
```

Parameter	Description
`all`	Display all authentication information for each authenticated interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port, available on the switch.

Mode Privileged Exec

Example To display all Web authentication information, enter the command:

```
awplus# show auth-web all
```

Output Figure 65-4: Example output from the **show auth-web** command

```
802.1X Port-Based Authentication Disabled
MAC-based Port Authentication Disabled
WEB-based Port Authentication Enabled
```

Related Commands

show dot1x
show auth-mac

show auth-web diagnostics

This command shows Web authentication diagnostics, optionally for the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

If no interface is specified then authentication diagnostics are shown for all interfaces.

Syntax

```
show auth-web diagnostics [interface <interface-list>]
```

Parameter	Description
`interface`	Specify ports to show.
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example To display authentication diagnostics for `port1.0.12`, enter the command:

```
awplus# show auth-web diagnostics interface port1.0.12
```

Output Figure 65-5: Example output from the **show auth-web diagnostics** command

```
Authentication Diagnostics for interface port1.0.12
    Supplicant address: 00d0.59ab.7037
        authEnterConnecting: 2
        authEaplogoffWhileConnecting: 1
        authEnterAuthenticating: 2
        authSuccessWhileAuthenticating: 1
        authTimeoutWhileAuthenticating: 1
        authFailWhileAuthenticating: 0
        authEapstartWhileAuthenticating: 0
        authEaplogoggWhileAuthenticating: 0
        authReauthsWhileAuthenticated: 0
        authEapstartWhileAuthenticated: 0
        authEaplogoffWhileAuthenticated: 0
        BackendResponses: 2
        BackendAccessChallenges: 1
        BackendOtherrequestToSupplicant: 3
        BackendAuthSuccess: 1
```

Related Commands show dot1x interface

show auth-web interface

This command shows the status for Web based authentication on the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

Use the optional diagnostics parameter to show authentication diagnostics for the specified interface. Use the optional sessionstatistics parameter to show authentication session statistics for the specified interface. Use the optional statistics parameter to show authentication diagnostics for the specified interface. Use the optional supplicant (client device) parameter to show the supplicant state for the specified interface.

Syntax

```
show auth-web interface <interface-list>
   [diagnostics|sessionstatistics|statistics|supplicant [brief]]
```

Parameter	Description
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.
`diagnostics`	Diagnostics.
`sessionstatistics`	Session statistics.
`statistics`	Statistics.
`supplicant`	Supplicant (client device).
`brief`	Brief summary of supplicant state.

Mode Privileged Exec

Example To display the Web based authentication status for `port1.0.12`, enter the command:

```
awplus# show auth-web interface port1.0.2
```

```
% Port-Control not configured on port1.0.2
```

To display Web authentication diagnostics for `port1.0.12`, enter the command:

```
awplus# show auth-web interface port1.0.12 diagnostics
```

```
Authentication Diagnostics for interface port1.0.2
    Supplicant address: 00d0.59ab.7037

show auth-web sessionstatistics

This command shows authentication session statistics for the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

Syntax `show auth-web sessionstatistics [interface <interface-list>]`

Parameter	Description
`interface`	Specify ports to show.
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example To display authentication statistics for `port1.0.12`, enter the command:

```
awplus# show auth-web sessionstatistics interface port1.0.12
```

Output Figure 65-6: Example output from the **show auth-web sessionstatistics** command

```
Authentication session statistics for interface port1.0.12
    session user name: manager
        session authentication method: Remote server
        session time: 19440 secs
        session terminat cause: Not terminated yet
```

show auth-web statistics interface

This command shows the authentication statistics for the specified interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port.

Syntax `show auth-web statistics interface <interface-list>`

Parameter	Description
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.

Mode Privileged Exec

Example To display Web authentication statistics for `port1.0.12`, enter the command:

```
awplus# show dot1x statistics interface port1.0.12
```

Related Commands show dot1x interface

show auth-web supplicant

This command shows the supplicant (client device) state when Web authentication is configured for the switch. This command shows a summary when the optional brief parameter is used.

Syntax `show auth-web supplicant [<macadd>] [brief]`

Parameter	Description
<macadd>	Mac (hardware) address of the supplicant Entry format is HHHH.HHHH.HHHH (hexadecimal).
`brief`	Brief summary of the supplicant state.

Mode Privileged Exec

Examples To display Web authenticated supplicant information on the switch, enter the command:

```
awplus# show auth-web supplicant
```

To display brief summary output for the Web authenticated supplicant on the switch, enter the command:

```
awplus# show auth-web supplicant brief
```

show auth-web supplicant interface

This command shows the supplicant (client device) state for the Web authenticated interface, which may be a static channel (or static aggregator) or a dynamic (or LACP) channel group or a switch port. This command shows a summary when the optional brief parameter is used.

Syntax

```
show auth-web supplicant interface <interface-list> [brief]
```

Parameter	Description
<interface-list>	The interfaces or ports to configure. An interface-list can be: ■ an interface (e.g. `vlan2`), a switch port (e.g. `port1.0.12`), a static channel group (e.g. `sa3`) or a dynamic (LACP) channel group (e.g. `po4`) ■ a continuous range of interfaces, ports, static channel groups or dynamic (LACP) channel groups separated by a hyphen; e.g. `vlan2-8`, or `port1.0.1-1.0.24`, or `sa2-4`, or `po1-3` ■ a comma-separated list of the above; e.g. `port1.0.1,port1.0.8-1.0.24`. Do not mix interface types in a list The specified interfaces must exist.
`brief`	Brief summary of the supplicant state.

Mode Privileged Exec

Examples To display the Web authenticated supplicant on the interface `port1.0.12`, enter the command:

```
awplus# show auth-web supplicant interface port1.0.12
```

To display brief summary output for the Web authenticated supplicant, enter the command:

```
awplus# show auth-web supplicant brief
```

show auth-web-server

This command shows the web authentication server configuration and status on the switch.

Syntax `show auth-web-server`

Mode Privileged Exec

Example To display web authentication server configuration and status, enter the command:

```
awplus# show auth-web-server
```

Output Figure 65-7: Example output from the **show auth-web-server** command

```
Web authentication server
    Server status: enabled
    Server address: -
    HTTP Port No: 80
    Security: enabled
    Certification: default
    SSL Port No: 443
    Redirect URL:
    HTTP Redirect: disabled
    Session keep: disabled
    PingPolling: disable
    PingInterval: 30
    Timeout: 1
    FailCount: 5

- Sample MAC Authentication Configuration 66.8
- Sample Web-Authentication Configuration 66.9
- Sample Tri-Authentication Configuration 66.10

AAA Introduction

AAA is the collective title for the three related functions of Authentication, Authorization and Accounting. These function can be applied in a variety of methods with a variety of servers. The purpose of the AAA commands is to map instances of the AAA functions to sets of servers.

The Authentication function can be performed in multiple contexts, such as authentication of users logging in at a console, or 802.1x authentication of devices connecting to Ethernet ports.

For each of these contexts, you may want to use different sets of servers for examining the proffered authentication credentials and deciding if they are valid. AAA Authentication commands enable you to specify which servers will be used for different types of authentication.

Available functions and server types

Authentication, Authorization and Accounting functions are available.

Authentication is performed in the following contexts:

- Login authentication of user shell sessions on the console port, and via telnet/SSH
- Enable password authentication for user shell sessions on the console port, and via telnet/SSH (TACACS+ only)
- 802.1x authentication of devices connecting to switch ports
- MAC authentication of devices connecting to switch ports
- Web-based authentication of devices connecting to switch ports

Authorization is performed in the following context:

- TACACS+ login authentication. Note that with the AlliedWare Plus TACACS+ implementation:
  - « authorization cannot be performed independently of the login authentication process
  - « authorization will not be attempted if enable password authentication is configured
  - « there are no authorization commands available

Accounting is performed in the following contexts:

- Accounting of console, telnet, and SSH login sessions
- Accounting of commands executed within user shell sessions (TACACS+ only)
- Accounting of 802.1x-authenticated connections
- Accounting of MAC-authenticated connections
- Accounting of Web-authenticated connections

The three types of servers that can be used are:

- Local user database
- RADIUS servers
- TACACS+ servers

Server Groups and Method Lists

There are two constructs that underlie the structure of the AAA commands:

- Server groups are lists of RADIUS servers
- Method Lists are lists of server types

Server Groups

A server group is defined by the command aaa group server. This command puts you into Server Group configuration mode. Once in that mode you can add servers to the group by using the command server auth-port.

Any number of servers can be added to a group. Typically, you will add servers which have already been configured by the command radius-server host. If you add a server that has not yet been configured by the command radius-server host, you will receive a warning that the server has not yet been configured, but the command will be accepted.

There is one server group that is always present on the switch by default that cannot be removed. It is the group simply named radius that comprises all servers that have been configured using the command radius-server host. As soon as a server is configured by the command radius-server host, it is automatically a member of the server group radius and cannot be removed from it.

Method Lists

A method list defines the set of server types that you want to be used for authenticating a user/device, and the order in which you want the server types to be used.

- You may want the usernames proffered for logging in at the console to be checked for in the local user database. You can create a server list that specifies local.
- You may want to check the TACACS+ servers first, and resort to the local user database if none of the TACACS+ servers respond. You can create a server list that specifies group tacacs+ first, followed by local.
- You may want to check the RADIUS servers first, and resort to the local user database if none of the RADIUS servers respond. You can create a server list that specifies group radius first, followed by local.

A method list defines the servers where authentication requests are sent. The first server listed is used to authenticate users; if that server fails then the next authentication server type in the method list is selected. This process continues until there is a successful authentication or until all server types fail.

When a user attempts to log in, the switch sends an authentication request to the first authentication server in the method list. If the first server in the list is reachable and it contains a username and password matching the authentication request, the user is authenticated and the login succeeds. If the authentication server denies the authentication request because of an incorrect username or password, the user login fails. If the first server in the method list is unreachable, the switch sends the request to the next server in the list, and so on.

For example, if the method list specifies `group tacacs+ local`, and a user attempts to log in with a password that does not match a user entry in the first TACACS+ server, if this TACACS+ server denies the authentication request, then the switch does not try any other TACACS+ servers not the local user database; the user login fails.

Default Method Lists

For every authentication or accounting type, it is always possible to define a method list called default. For most of the authentication and accounting types, the only method list that can be defined is default.

As soon as the default method list is defined for a given authentication or accounting type, it is automatically applied as the method list to be used for any instance of that type of authentication or accounting, except for instances to which another named method list has been specifically applied.

Configuring AAA Login Authentication

To configure AAA authentication, create default or a named method list for different authentication types. In the case of login authentication, the named method lists are then applied to consoles or VTY lines.

AAA Configuration Tasks

To define how a given accounting or authentication type will be applied to a given port or line:

- either create a server group using the aaa group server command (RADIUS only),
- or create a method list for the authentication or accounting type as required,
- then apply that method list to the port or line as required.

Step 1: Define a group of RADIUS Servers:

Create a server group using the aaa group server command.

To create a RADIUS server group named `GROUP1` with hosts `192.168.1.1`, `192.168.2.1` and `192.168.3.1`, use the commands:

```
awplus(config)# aaa group server radius GROUP1
awplus(config-sg)# server 192.168.1.1 auth-port 1812 acct-port 1813
awplus(config-sg)# server 192.168.2.1 auth-port 1812 acct-port 1813
awplus(config-sg)# server 192.168.3.1 auth-port 1812 acct-port 1813
```

Step 2: Specify the login authentication or accounting Method List:

Create a method list for the authentication (aaa authentication login) or accounting (aaa accounting login) type as required.

To configure a user login authentication method list called `USERS` to use first all available RADIUS servers for user login authentication and then the local user database, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa authentication login default group radius local
```

To configure RADIUS accounting for login shell sessions, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa accounting login default start-stop group radius
```

To configure a user login authentication method list called `USERS` to use first the TACACS+ servers for user login authentication and then the local user database, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa authentication login USERS group tacacs+
local
```

Step 3: Apply Method List to Interface Port or Line:

Apply that method list to the port or line as required.

```
awplus# configure terminal
awplus(config)# line console 0
awplus(config-line)# login authentication USERS
```

For most Authentication and Accounting types, the only possible server list is default, and the only server that can be put into it is radius. You will typically use all RADIUS servers, so group radius can be used, rather than having to create a specific user group. Often the configuration of a given Authentication or Accounting type will consist of a single command, the command that defines the default server list, which contains just one server.

AAA 802.1x Authentication Configuration:

AAA 802.1x authentication will typically be configured with the following commands.

To enable 802.1x Authentication globally for all RADIUS servers, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa authentication dot1x default group radius
```

Sample Authentication Configurations

Sample 802.1X Authentication Configuration

See the below sample configuration script for a sample 802.1X authentication configuration. Copy and paste then edit the sample 802.1X authentication configuration in your config file. See the edit command in the Chapter 7, File Management Commands for further information.

Output

Figure 66-1: Sample 802.1X Authentication Configuration

```
!
 radius-server host 127.0.0.1 key awplus-local-radius-server
!
 aaa authentication dot1x default group radius
!
 radius-server local
 server enable
 nas 127.0.0.1 key awplus-local-radius-server
 user guest password guest!
!
 no spanning-tree rstp enable
!
 interface port1.0.1
 switchport
 switchport mode access
 dot1x port-control auto
!
 interface vlan1
 ip address 192.168.1.120/24
!
```

The 802.1X authentication feature needs the aaa authentication dot1x command and the dot1x port-control command configured on an interface. See Chapter 67, AAA Commands and Chapter 63, 802.1X Commands for command information to edit this configuration.

Local RADIUS Server has been configured to use 802.1X authentication in this sample configuration. See the radius-server local and server enable commands in Chapter 73, Local RADIUS Server Commands for command information to edit this sample configuration.

This sample configuration enables 802.1X authentication on interface `vlan1` with IP address `192.168.1.120`. Change the VLAN ID and IP address as required for your configuration.

Sample MAC Authentication Configuration

See the below sample configuration script for a sample MAC authentication configuration. Copy, paste, and edit the sample MAC authentication configuration in the config file. See the edit command in the Chapter 7, File Management Commands for further information.

Output

Figure 66-2: Sample MAC Authentication Configuration

```
!
 radius-server host 127.0.0.1 key awplus-local-radius-server
!
 aaa authentication auth-mac default group radius
!
 radius-server local
 server enable
 nas 127.0.0.1 key awplus-local-radius-server
 user 00-d0-59-ab-70-37 password 00-d0-59-ab-70-37
!
 no spanning-tree rstp enable
!
 interface port1.0.1
 switchport
 switchport mode access
 auth-mac enable
!
 interface vlan1
 ip address 192.168.1.120/24
!
```

The MAC authentication feature needs the aaa authentication auth-mac and the auth-mac enable commands configured on an interface. See Chapter 67, AAA Commands and Chapter 65, Authentication Commands for command information to edit this configuration.

Local RADIUS Server has been configured to use MAC authentication in this sample configuration. See the radius-server local and server enable commands in Chapter 73, Local RADIUS Server Commands for command information to edit this sample configuration.

See the user (RADIUS server) command in Chapter 73, Local RADIUS Server Commands for command information to edit the MAC address of the supplicant for use with local RADIUS server as the RADIUS user name and the user password, as shown in the above configuration.

This configuration enables MAC authentication on `vlan1` with IP address `192.168.1.120`. Change the interface VLAN ID, MAC, and IP addresses as needed in your configuration.

Sample Web-Authentication Configuration

See the below sample configuration script for a sample Web-authentication configuration. Copy, paste, and edit the sample Web-authentication configuration for your config file. See the edit command in the Chapter 7, File Management Commands for further information.

Output

Figure 66-3: Sample Web-Authentication Configuration

```
!
 radius-server host 127.0.0.1 key awplus-local-radius-server
!
 aaa authentication auth-web default group radius
!
 radius-server local
 server enable
 nas 127.0.0.1 key awplus-local-radius-server
 user guest encrypted password
 l+lWcLjLm29bCAXwWRPHXK0PFlsA7gNpR+P7wO4kwQQ=
!
 no spanning-tree rstp enable
!
 interface port1.0.1
 switchport
 switchport mode access
 auth-web enable
!
 interface vlan1
 ip address 192.168.1.120/24
!
```

The Web-authentication feature needs the aaa authentication auth-web and the auth-web enable commands configured on an interface. See Chapter 67, AAA Commands and Chapter 65, Authentication Commands for command information to edit this configuration.

Local RADIUS Server has been configured to use Web-authentication in this sample configuration. See the radius-server local and server enable commands in Chapter 73, Local RADIUS Server Commands for command information to edit this sample configuration.

The above sample Web-authentication configuration requires the user name '`guest`' with password '`guest!`' on IP address `192.168.1.120` from interface `port1.0.1`.

Sample Tri-Authentication Configuration

See the below sample configuration script for a sample tri-authentication configuration that configures 802.1X authentication, MAC authentication, and Web-authentication on the same interface. Copy, paste, and edit the sample tri-authentication configuration for your config file. See the edit command in the Chapter 7, File Management Commands for further information.

Output

Figure 66-4: Sample Tri-Authentication Configuration

```
!
 radius-server host 127.0.0.1 key awplus-local-radius-server
!
 aaa authentication dot1x default group radius
 aaa authentication auth-mac default group radius
 aaa authentication auth-web default group radius
!
 radius-server local
 server enable
 nas 127.0.0.1 key awplus-local-radius-server
 user guest password guest!
 user 00-d0-59-ab-70-37 password 00-d0-59-ab-70-37
!
 no spanning-tree rstp enable
!
 interface port1.0.1
 switchport
 switchport mode access
 dot1x port-control auto
 auth-mac enable
 auth-web enable
!
 interface vlan1
 ip address 192.168.1.120/24
!
```

The 802.1X authentication feature needs the aaa authentication dot1x command and the dot1x port-control command configured on an interface. See Chapter 67, AAA Commands and Chapter 63, 802.1X Commands for command information to edit this configuration.

The MAC authentication feature needs the aaa authentication auth-mac and the auth-mac enable commands configured on an interface. See Chapter 67, AAA Commands and Chapter 65, Authentication Commands for command information to edit this configuration.

The Web-authentication feature needs the aaa authentication auth-web and the auth-web enable commands configured on an interface. See Chapter 67, AAA Commands and Chapter 65, Authentication Commands for command information to edit this configuration.

Local RADIUS Server has been configured to use tri-authentication in this sample configuration. See the radius-server local and server enable commands in Chapter 73, Local RADIUS Server Commands for command information to edit this sample configuration.

This sample tri-authentication configuration requires a user name '`guest`' with password '`guest!`' on IP address `192.168.1.120` from `port1.0.1`. Note this sample also configures 802.1X and MAC authentication on `vlan1` with IP address `192.168.1.120`. Change the interface VLAN ID, MAC and IP address as needed for your configuration.

Note that when tri-authentication is applied to the same interface then the order of execution is MAC authentication first, then 802.1X or Web-authentication, if MAC authentication fails.

Chapter 67: AAA Commands

Command List 67.2
aaa accounting auth-mac default 67.2
aaa accounting auth-web default 67.4
aaa accounting commands 67.6
aaa accounting dot1x 67.8
aaa accounting login 67.10

clear aaa local user lockout 67.25
debug aaa 67.26
login authentication 67.27
show debugging aaa 67.28
undebug aaa 67.28

Command List

This chapter provides an alphabetical reference for AAA commands for Authentication, Authorization and Accounting. For more information, see Chapter 66, AAA Introduction and Configuration.

aaa accounting auth-mac default

This command configures a default accounting method list for MAC-based Authentication. The default accounting method list specifies what type of accounting messages are sent and specifies which RADIUS Servers the accounting messages are sent to. The default accounting method list is automatically applied to interfaces with MAC-based Authentication enabled.

Use the no variant of this command to disable AAA accounting for MAC-based Authentication globally.

Syntax

```
aaa accounting auth-mac default {start-stop|stop-only|none}
   group {<group-name>|radius}

no aaa accounting auth-mac default
```

Parameter	Description
`start-stop`	Start and stop records to be sent.
`stop-only`	Stop records to be sent.
`none`	No accounting record to be sent.
`<group-name>`	Server group name.
`radius`	Use all RADIUS servers

Default RADIUS accounting for MAC-based Authentication is disabled by default

Mode Global Configuration

Usage There are two ways to define servers where RADIUS accounting messages are sent:

- group radius : use all RADIUS servers configured by radius-server host command
- group <*group-name*> : use the specified RADIUS server group configured with the aaa group server command

The accounting event to send to the RADIUS server is configured with the following options:

- start-stop : sends a start accounting message at the beginning of a session and a stop accounting message at the end of the session.
- stop-only : sends a stop accounting message at the end of a session.
- none : disables accounting.

Examples To enable RADIUS accounting for MAC-based Authentication, and use all available RADIUS Servers, use the commands:

```
awplus# configure terminal
awplus(config)# aaa accounting auth-mac default start-stop
group radius
```

To disable RADIUS accounting for MAC-based Authentication, use the commands:

```
awplus# configure terminal
awplus(config)# no aaa accounting auth-mac default
```

Related Commands aaa authentication auth-mac

aaa accounting auth-web default

This command configures a default accounting method list for Web-based Port Authentication. The default accounting method list specifies what type of accounting messages are sent and specifies which RADIUS Servers the accounting messages are sent to. The default accounting method list is automatically applied to interfaces with Web-based Authentication enabled.

Use the no variant of this command to disable AAA accounting for Web-based Port Authentication globally.

Syntax

```
aaa accounting auth-web default {start-stop|stop-only|none}
   group {<group-name>|radius}

no aaa accounting auth-web default
```

Parameter	Description
`start-stop`	Start and stop records to be sent.
`stop-only`	Stop records to be sent.
`none`	No accounting record to be sent.
`<group-name>`	Server group name.
`radius`	Use all RADIUS servers.

Default RADIUS accounting for WEB-based Port Authentication is disabled by default.

Mode Global Configuration

Usage There are two ways to define servers where RADIUS accounting messages are sent:

- group radius : use all RADIUS servers configured by radius-server host command
- group <*group-name*> : use the specified RADIUS server group configured with the aaa group server command

Configure the accounting event to be sent to the RADIUS server with the following options:

- start-stop : sends a start accounting message at the beginning of a session and a stop accounting message at the end of the session.
- stop-only : sends a stop accounting message at the end of a session.
- none : disables accounting.

Examples To enable RADIUS accounting for Web-based Authentication, and use all available RADIUS Servers, use the commands:

```
awplus# configure terminal
awplus(config)# aaa accounting auth-web default start-stop
                group radius
```

To disable RADIUS accounting for Web-based Authentication, use the commands:

```
awplus# configure terminal
awplus(config)# no aaa accounting auth-web default
```

Related Commands aaa authentication auth-web

aaa accounting commands

Use this command to configure and enable TACACS+ command accounting. When command accounting is enabled, information about a command entered at a specified privilege level on a device is sent to a TACACS+ server. To account for all commands entered on a device you need to configure command accounting for each discrete privilege level. A command accounting record includes the command as entered for the specified privilege level, the date and time each command execution finished, and the username of the user who executed the command.

This command creates a default method list that is applied to every console and vty line. The stop-only parameter indicates that an accounting message is sent to the TACACS+ server when a command has stopped executing.

Note that up to four TACACS+ servers can be configured for accounting. The servers are checked for reachability in the order they are configured and only the first reachable server is used. If no server is found the accounting message is dropped.

Use the no variant of this command to disable command accounting.

Syntax

```
aaa accounting commands <1-15> default stop-only group tacacs+

no aaa accounting commands <1-15> default
```

Parameter	Description
<1-15>	The privilege level, in the range 1 to 15.

Default TACACS+ command accounting is disabled by default.

Mode Global Configuration

Usage When command accounting is enabled, the command as entered is included in the accounting packets sent to the TACACS+ accounting server.

You cannot enable command accounting if a trigger is configured. An error message is displayed if you attempt to enable command accounting and a trigger is configured.

The show tech-support command runs a number of commands and each command is accounted separately.

When the copy <*filename*> running-config command is executed all the commands of a configuration file copied into the running-config are accounted separately.

Examples To configure command accounting for privilege level 15 commands, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa accounting commands 15 default stop-only
group tacacs+
```

To disable command accounting for privilege level 15 commands, use the following commands:

```
awplus# configure terminal
awplus(config)# no aaa accounting commands 15 default
```

Related Commands

aaa authentication login
aaa accounting login
accounting login
tacacs-server host

aaa accounting dot1x

This command configures the default accounting method list for IEEE 802.1x-based Authentication. The default accounting method list specifies what type of accounting messages are sent and specifies which RADIUS Servers the accounting messages are sent to. The default accounting method list is automatically applied to interfaces with IEEE 802.1x-based Authentication enabled.

Use the no variant of this command to disable AAA accounting for 802.1x-based Port Authentication globally.

Syntax

```
aaa accounting dot1x default {start-stop|stop-only|none}
   group {<group-name>|radius}

no aaa accounting dot1x default
```

Parameter	Description
`start-stop`	Start and stop records to be sent.
`stop-only`	Stop records to be sent.
`none`	No accounting record to be sent.
`<group-name>`	Server group name.
`radius`	Use all RADIUS servers.

Default RADIUS accounting for 802.1X-based Port Authentication is disabled by default. (There is no default server set by default).

Mode Global Configuration

Usage There are two ways to define servers where RADIUS accounting messages will be sent:

- group radius : use all RADIUS servers configured by radius-server host command
- group <*group-name*> : use the specified RADIUS server group configured with the aaa group server command

The accounting event to send to the RADIUS server is configured by the following options:

- start-stop : sends a start accounting message at the beginning of a session and a stop accounting message at the end of the session.
- stop-only : sends a stop accounting message at the end of a session.
- none : disables accounting.

Example To enable RADIUS accounting for 802.1x-based Authentication, and use all available RADIUS Servers, use the commands:

```
awplus# configure terminal
awplus(config)# aaa accounting dot1x default start-stop group
radius
```

To disable RADIUS accounting for 802.1x-based Authentication, use the commands:

```
awplus# configure terminal
awplus(config)# no aaa accounting dot1x default
```

Related Commands

aaa accounting update
aaa authentication dot1x
aaa group server
dot1x port-control
radius-server host

aaa accounting login

This command configures RADIUS and TACACS+ accounting for login shell sessions. The specified method list name can be used by the accounting login command in the Line Configuration mode. If the default parameter is specified, then this creates a default method list that is applied to every console and vty line, unless another accounting method list is applied on that line.

Note that unlimited RADIUS servers and up to four TACACS+ servers can be configured and consulted for accounting. The first server configured is regarded as the primary server and if the primary server fails then the backup servers are consulted in turn. A backup server is consulted if the primary server fails, i.e is unreachable.

Use the no variant of this command to remove an accounting method list for login shell sessions configured by an aaa accounting login command. If the method list being deleted is already applied to a console or vty line, accounting on that line will be disabled. If the default method list name is removed by this command, it will disable accounting on every line that has the default accounting configuration.

Syntax

```
aaa accounting login {default|<list-name>}
   {start-stop|stop-only|none} {group {radius|tacacs+|<group-name>}}

no aaa accounting login {default|<list-name>}
```

Parameter	Description
`default`	Default accounting method list.
`<list-name>`	Named accounting method list.
`start-stop`	Start and stop records to be sent.
`stop-only`	Stop records to be sent.
`none`	No accounting record to be sent.
`group`	Specify the servers or server group where accounting packets are sent.
`radius`	Use all RADIUS servers configured by the radius-server host command on page 69.6.
`tacacs+`	Use all TACACS+ servers configured by the tacacs-server host command.
`<group-name>`	Use the specified RADIUS server group, as configured by the aaa group server command.

Default Accounting for login shell sessions is disabled by default.

Mode Global Configuration

Usage This command enables you to define a named accounting method list. The items that you define in the accounting options are:

- the types of accounting packets that will be sent
- the set of servers to which the accounting packets will be sent

You can define a default method list with the name `default` and any number of other named method lists. The `<list-name>` for any method list that you define can then be used as the `<list-name>` parameter in the accounting login command available from Line Configuration mode.

If the method list name already exists, the command will replace the existing configuration with the new one.

There are two ways to define servers where RADIUS accounting messages are sent:

- group radius : use all RADIUS servers configured by radius-server host command
- group **<*group-name*>** : use the specified RADIUS server group configured with the aaa group server command

There is one way to define servers where TACACS+ accounting messages are sent:

- group tacacs+ : use all TACACS+ servers configured by tacacs-server host command

The accounting event to send to the RADIUS or TACACS+ server is configured with the following options:

- start-stop : sends a start accounting message at the beginning of a session and a stop accounting message at the end of the session.
- stop-only : sends a stop accounting message at the end of a session.
- none : disables accounting.

Examples To configure RADIUS accounting for login shell sessions, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa accounting login default start-stop group
radius
```

To configure TACACS+ accounting for login shell sessions, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa accounting login default start-stop group
tacacs+
```

To reset the configuration of the default accounting list, use the following commands:

```
awplus# configure terminal
awplus(config)#  no aaa accounting login default
```

Related Commands
aaa accounting commands
aaa authentication login
aaa accounting login
aaa accounting update
accounting login
radius-server host
tacacs-server host

aaa accounting update

This command enables periodic accounting reporting to either the RADIUS or TACACS+ accounting server(s) wherever login accounting has been configured.

Note that unlimited RADIUS servers and up to four TACACS+ servers can be configured and consulted for accounting. The first server configured is regarded as the primary server and if the primary server fails then the backup servers are consulted in turn. A backup server is consulted if the primary server fails, i.e is unreachable.

Use the no variant of this command to disable periodic accounting reporting to the accounting server(s).

Syntax

```
aaa accounting update [periodic <1-65535>]
no aaa accounting update
```

Parameter	Description
`periodic`	Send accounting records periodically.
<1-65535>	The interval to send accounting updates (in minutes). The default is 30 minutes.

Default Periodic accounting update is disabled by default.

Mode Global Configuration

Usage Use this command to enable the device to send periodic AAA login accounting reports to the accounting server. When periodic accounting report is enabled, interim accounting records are sent according to the interval specified by the periodic parameter. The accounting updates are start messages.

If the no variant of this command is used to disable periodic accounting reporting, any interval specified by the periodic parameter is reset to the default of 30 minutes when accounting reporting is reenabled, unless this interval is specified.

Example To configure the switch to send period accounting updates every 30 minutes, the default period, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa accounting update
```

To configure the switch to send period accounting updates every 10 minutes, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa accounting update periodic 10
```

To disable periodic accounting update wherever accounting has been configured, use the following commands:

```
awplus# configure terminal
awplus(config)# no aaa accounting update
```

Related Commands
aaa accounting auth-mac default
aaa accounting auth-web default
aaa accounting dot1x
aaa accounting login

aaa authentication auth-mac

This command enables MAC-based Port Authentication globally and allows you to specify an authentication method list. It is automatically applied to every interface running MAC-based Port Authentication.

Use the no variant of this command to globally disable MAC-based Port Authentication.

Syntax

```
aaa authentication auth-mac default group {<group-name>|radius}
no aaa authentication auth-mac default
```

Parameter	Description
<group-name>	Server group name.
radius	Use all RADIUS servers.

Default MAC-based Port Authentication is disabled by default.

Mode Global Configuration

Usage There are two ways to define servers where RADIUS accounting messages are sent:

- group radius : use all RADIUS servers configured by radius-server host command
- group **<*group-name*>** : use the specified RADIUS server group configured with the aaa group server command

All configured RADIUS Servers are automatically members of the server group radius. If a server is added to a named group **<*group-name*>**, it also remains a member of the group radius.

Example To enable MAC-based Port Authentication globally for all RADIUS servers, and use all available RADIUS servers, use the commands:

```
awplus# configure terminal
awplus(config)# aaa authentication auth-mac default group
radius
```

To disable MAC-based Port Authentication, use the commands:

```
awplus# configure terminal
awplus(config)# no aaa authentication auth-mac default
```

Related Commands
aaa accounting auth-mac default
auth-mac enable

aaa authentication auth-web

This command enables Web-based Port Authentication globally and allows you to enable an authentication method list (in this case, a list of RADIUS Servers). It is automatically applied to every interface running Web-based Port Authentication.

Use the no variant of this command to globally disable Web-based Port Authentication.

Syntax

```
aaa authentication auth-web default group {<group-name>|radius}
no aaa authentication auth-web default
```

Parameter	Description
<group-name>	Server group name.
radius	Use all RADIUS servers.

Default Web-based Port Authentication is disabled by default.

Mode Global Configuration

Usage There are two ways to define servers where RADIUS accounting messages are sent:

- group radius : use all RADIUS servers configured by radius-server host command
- group ***<group-name>*** : use the specified RADIUS server group configured with the aaa group server command

Example To enable Web-based Port Authentication globally for all RADIUS servers, and use all available RADIUS servers, use the commands:

```
awplus# configure terminal
awplus(config)# aaa authentication auth-web default group
radius
```

To disable Web-based Port Authentication, use the commands:

```
awplus# configure terminal
awplus(config)# no aaa authentication auth-web default
```

Related Commands aaa accounting auth-web default
auth-mac enable

aaa authentication dot1x

This command enables 802.1X-based Port Authentication globally and allows you to enable an authentication method list. It is automatically applied to every interface running 802.1X-based Port Authentication.

Use the no variant of this command to globally disable 802.1X-based Port Authentication.

Syntax

```
aaa authentication dot1x default group {<group-name>|radius}
no aaa authentication dot1x default
```

Parameter	Description
`radius`	Use all RADIUS servers.
<group-name>	Server group name.

Default 802.1x-based Port Authentication is disabled by default.

Mode Global Configuration

Usage Use this command to specify the default method list to use for authentication on all switch ports with 802.1X enabled. Use the no variant of this command to reset the default authentication method list for 802.1X, to its default, that is, to use the group radius, containing all RADIUS servers configured by the radius-server host command.

There are two ways to define servers where RADIUS accounting messages are sent:

- group radius : use all RADIUS servers configured by radius-server host command
- group **<*group-name*>** : use the specified RADIUS server group configured with the aaa group server command

Example To enable 802.1X-based Port Authentication globally with all RADIUS servers, and use all available RADIUS servers, use the command:

```
awplus# configure terminal
awplus(config)# aaa authentication dot1x default group radius
```

To disable 802.1X-based Port Authentication, use the command:

```
awplus# configure terminal
awplus(config)# no aaa authentication dot1x default
```

Related Commands
aaa accounting dot1x
aaa group server
dot1x port-control
radius-server host

aaa authentication enable default group tacacs+

This command enables AAA authentication to determine the privilege level a user can access for passwords authenticated against the TACACS+ server.

Use the no variant of this command to disable privilege level authentication.

Syntax

```
aaa authentication enable default group tacacs+ [local] [none]
no aaa authentication enable default
```

Parameter	Description
`local`	Use the locally configured enable password (enable password command) for authentication.
`none`	No authentication.

Default Local privilege level authentication is enabled by default (aaa authentication enable default local command).

Mode Global Configuration

Usage A user is configured on a TACACS+ server with a maximum privilege level. When they enter the enable (Privileged Exec mode) command they are prompted for an enable password which is authenticated against the TACACS+ server. If the password is correct and the specified privilege level is equal to or less than the users maximum privilege level, then they are granted access to that level. If the user attempts to access a privilege level that is higher than their maximum configured privilege level, then the authentication session will fail and they will remain at their current privilege level.

Note If both local and none are specified, you must always specify local first.

If the TACACS+ server goes offline, or is not reachable during enable password authentication, and command level authentication is configured as:

- aaa authentication enable default group tacacs+
  then the user is never granted access to Privileged Exec mode.
- aaa authentication enable default group tacacs+ local
  then the user is authenticated using the locally configured enable password, which if entered correctly grants the user access to Privileged Exec mode. If no enable password is locally configured (enable password command), then the enable authentication will fail until the TACACS+ server becomes available again.
- aaa authentication enable default group tacacs+ none
  then the user is granted access to Privileged Exec mode with no authentication. This is true even if a locally configured enable password is configured.
- aaa authentication enable default group tacacs+ local none
  then the user is authenticated using the locally configured enable password. If no enable password is locally configured, then the enable authentication will grant access to Privileged Exec mode with no authentication.

If the password for the user is not successfully authenticated by the server, then the user is again prompted for an enable password when they enter enable via the CLI.

Example To enable a privilege level authentication method that will not allow the user to access Privileged Exec mode if the TACACS+ server goes offline, or is not reachable during enable password authentication, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa authentication enable default group tacacs+
```

To enable a privilege level authentication method that will allow the user to access Privileged Exec mode if the TACACS+ server goes offline, or is not reachable during enable password authentication, and a locally configured enable password is configured, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa authentication enable default group tacacs+
local
```

To disable privilege level authentication, use the following commands:

```
awplus# configure terminal
awplus(config)# no aaa authentication enable default
```

Related Commands
aaa authentication login
aaa authentication enable default local
enable (Privileged Exec mode)
enable password
enable secret
tacacs-server host

aaa authentication enable default local

This command enables AAA authentication to determine the privilege level a user can access for passwords authenticated locally.

Syntax `aaa authentication enable default local`

Default Local privilege level authentication is enabled by default.

Mode Global Configuration

Usage The privilege level configured for a particular user in the local user database is the privilege threshold above which the user is prompted for an enable (Privileged Exec mode) command.

Example To enable local privilege level authentication command, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa authentication enable default local
```

To disable privilege level authentication, use the following commands:

```
awplus# configure terminal
awplus(config)# no aaa authentication enable default
```

Related Commands
aaa authentication enable default group tacacs+
aaa authentication login
enable (Privileged Exec mode)
enable password
enable secret
tacacs-server host

aaa authentication login

Use this command to create an ordered list of methods to use to authenticate user login, or to replace an existing method list with the same name. Specify one or more of the options local or group, in the order you want them to be applied. If the default method list name is specified, it is applied to every console and VTY line immediately unless another method list is applied to that line by the login authentication command. To apply a non-default method list, you must also use the login authentication command.

Use the no variant of this command to remove an authentication method list for user login. The specified method list name is deleted from the configuration. If the method list name has been applied to any console or VTY line, user login authentication on that line will fail.

Note that the no aaa authentication login default command does not remove the default method list. This will return the default method list to its default state (local is the default).

Syntax

```
aaa authentication login {default|<list-name>}
   {[local] [group {radius|tacacs+|<group-name>}]}

no aaa authentication login {default|<list-name>}
```

Parameter	Description
`default`	Set the default authentication server for user login.
`<list-name>`	Name of authentication server.
`local`	Use the local username database.
`group`	Use server group.
`radius`	Use all RADIUS servers configured by the radius-server host command on page 69.6.
`tacacs+`	Use all TACACS+ servers configured by the tacacs-server host command.
`<group-name>`	Use the specified RADIUS server group, as configured by the aaa group server command.

Default If the default server is not configured using this command, user login authentication uses the local user database only.

If the default method list name is specified, it is applied to every console and VTY line immediately unless a named method list server is applied to that line by the login authentication command.

local is the default state for the default method list unless a named method list is applied to that line by the login authentication command. Reset to the default method list using the no aaa authentication login default command.

Mode Global Configuration

Usage When a user attempts to log in, the switch sends an authentication request to the first authentication server in the method list. If the first server in the list is reachable and it contains a username and password matching the authentication request, the user is authenticated and the login succeeds. If the authentication server denies the authentication request because of an incorrect username or password, the user login fails. If the first server in the method list is unreachable, the switch sends the request to the next server in the list, and so on.

For example, if the method list specifies group tacacs+ local, and a user attempts to log in with a password that does not match a user entry in the first TACACS+ server, if this TACACS+ server denies the authentication request, then the switch does not try any other TACACS+ servers not the local user database; the user login fails.

Examples To configure the default authentication method list for user login to use first all available RADIUS servers for user login authentication and then the local user database, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa authentication login default group radius
local
```

To configure a user login authentication method list called `USERS` to use first the RADIUS server group `RAD_GROUP1` for user login authentication and then the local user database, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa authentication login USERS group
RAD_GROUP1 local
```

To configure a user login authentication method list called `USERS` to use first the TACACS+ servers for user login authentication and then the local user database, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa authentication login USERS group tacacs+
local
```

To return to the default method list (local is the default server), use the following commands:

```
awplus# configure terminal
awplus(config)# no aaa authentication login default
```

To delete an existing authentication method list `USERS` created for user login authentication, use the following commands:

```
awplus# configure terminal
awplus(config)# no aaa authentication login USERS
```

Related Commands aaa accounting commands

login authentication

aaa group server

This command configures a RADIUS server group. A server group can be used to specify a subset of RADIUS servers in aaa commands. The group name radius is predefined, which includes all RADIUS servers configured by the radius-server host command.

RADIUS servers are added to a server group using the server command. Each RADIUS server should be configured using the radius-server host command.

Use the no variant of this command to remove an existing RADIUS server group.

Syntax

```
aaa group server radius <group-name>
no aaa group server radius <group-name>
```

Parameter	Description
<group-name>	Server group name.

Mode Global Configuration

Usage Use this command to create an AAA group of RADIUS servers, and to enter Server Group Configuration mode, in which you can add servers to the group. Use a server group to specify a subset of RADIUS servers in AAA commands. Each RADIUS server must be configured by the radius-server host command. To add RADIUS servers to a server group, use the server command.

Example To create a RADIUS server group named `GROUP1` with hosts `192.168.1.1`, `192.168.2.1` and `192.168.3.1`, use the commands:

```
awplus(config)# aaa group server radius GROUP1
awplus(config-sg)# server 192.168.1.1 auth-port 1812 acct-
port 1813
awplus(config-sg)# server 192.168.2.1 auth-port 1812 acct-
port 1813
awplus(config-sg)# server 192.168.3.1 auth-port 1812 acct-
port 1813
```

To remove a RADIUS server group named `GROUP1` from the configuration, use the command:

```
awplus(config)# no aaa group server radius GROUP1
```

aaa local authentication attempts lockout-time

This command configures the duration of the user lockout period.

Use the no variant of this command to restore the duration of the user lockout period to its default of 300 seconds (5 minutes).

Syntax

```
aaa local authentication attempts lockout-time <lockout-tiime>
no aaa local authentication attempts lockout-time
```

Parameter	Description
<lockout-time>	<0-10000>. Time in seconds to lockout the user.

Mode Global Configuration

Default The default for the lockout-time is 300 seconds (5 minutes).

Usage While locked out all attempts to login with the locked account will fail. The lockout can be manually cleared by another privileged account using the clear aaa local user lockout command.

Example To configure the lockout period to 10 minutes (600 seconds), use the commands:

```
awplus# configure terminal
awplus(config)# aaa local authentication attempts lockout-time
600
```

To restore the default lockout period of 5 minutes (300 seconds), use the commands:

```
awplus# configure terminal
awplus(config)# no aaa local authentication attempts
lockout-time
```

Related Commands aaa local authentication attempts max-fail

aaa local authentication attempts max-fail

This command configures the maximum number of failed login attempts before a user account is locked out. Every time a login attempt fails the failed login counter is incremented.

Use the no variant of this command to restore the maximum number of failed login attempts to the default setting (5 failed login attempts).

Syntax

```
aaa local authentication attempts max-fail <failed-logins>
no aaa local authentication attempts max-fail
```

Parameter	Description
<failed-logins>	<1-32>. Number of login failures allowed before locking out a user.

Mode Global Configuration

Default The default for the maximum number of failed login attempts is 5 failed login attempts.

Usage When the failed login counter reaches the limit configured by this command that user account is locked out for a specified duration configured by the aaa local authentication attempts lockout-time command.

When a successful login occurs the failed login counter is reset to 0. When a user account is locked out all attempts to login using that user account will fail.

Example To configure the number of login failures that will lock out a user account to 2 login attempts, use the commands:

```
awplus# configure terminal
awplus(config)# aaa local authentication attempts max-fail 2
```

To restore the number of login failures that will lock out a user account to the default number of login attempts (5 login attempts), use the commands:

```
awplus# configure terminal
awplus(config)# no aaa local authentication attempts max-fail
```

Related Commands aaa local authentication attempts lockout-time
clear aaa local user lockout

accounting login

This command applies a login accounting method list to console or vty lines for user login. When login accounting is enabled using the aaa accounting login command, logging events generate an accounting record to the accounting server configured using aaa accounting login.

The accounting method list must be configured first using the aaa accounting login command. If an accounting method list is specified that has not been created by the aaa accounting login command then accounting will be disabled on the specified lines.

The no variant of this command resets AAA (Authentication, Authorization, Accounting) Accounting applied to console or vty lines for local or remote login. default login accounting is applied after issuing the no accounting login command. Accounting is disabled with default.

Syntax

```
accounting login {default|<list-name>}
no accounting login
```

Parameter	Description
`default`	Default accounting method list.
<list-name>	Named accounting method list.

Default By default login accounting is disabled in the default accounting server. No accounting will be performed until accounting is enabled using the aaa accounting login command beforehand.

Mode Line Configuration

Example To apply the accounting server `USERS` to all vty lines use the following commands:

```
awplus# configure terminal
awplus(config)# line vty 0 32
awplus(config-line)# accounting login USERS
```

To reset accounting for login sessions on the console, use the following commands:

```
awplus# configure terminal
awplus(config)# line console 0
awplus(config-line)# no accounting login
```

Related Commands aaa accounting commands
aaa accounting login

clear aaa local user lockout

Use this command to clear the lockout on a specific user account or all user accounts.

Syntax

```
clear aaa local user lockout {username <username>|all}
```

Parameter	Description
`username`	Clear lockout for the specified user.
<username>	Specifies the user account.
`all`	Clear lockout for all user accounts.

Mode Privileged Exec

Examples To unlock the user account '`bob`' use the following command:

```
awplus# clear aaa local user lockout username bob
```

To unlock all user accounts use the following command:

```
awplus# clear aaa local user lockout all
```

Related Commands aaa local authentication attempts lockout-time

debug aaa

This command enables AAA debugging.

Use the no variant of this command to disable AAA debugging.

Syntax

```
debug aaa [accounting|all|authentication|authorization]
no debug aaa [accounting|all|authentication|authorization]
```

Parameter	Description
`accounting`	Accounting debugging.
`all`	All debugging options are enabled.
`authentication`	Authentication debugging.
`authorization`	Authorization debugging.

Default AAA debugging is disabled by default.

Mode Privileged Exec

Example To enable authentication debugging for AAA, use the command:

```
awplus# debug aaa authentication
```

To disable authentication debugging for AAA, use the command:

```
awplus# no debug aaa authentication
```

Related Commands show debugging aaa
undebug aaa

login authentication

Use this command to apply an AAA server for authenticating user login attempts from a console or remote logins on these console or VTY lines. The authentication method list must be specified by the aaa authentication login command. If the method list has not been configured by the aaa authentication login command, login authentication will fail on these lines.

Use the no variant of this command to reset AAA Authentication configuration to use the default method list for login authentication on these console or VTY lines.

Command Syntax

```
login authentication {default|<list-name>}
no login authentication
```

Parameter	Description
`default`	The default authentication method list. If the default method list has not been configured by the aaa authentication login command, the local user database is used for user login authentication.
<list-name>	Named authentication server.

Default The default login authentication method list, as specified by the aaa authentication login command, is used to authenticate user login. (If this has not been specified, the default is to use the local user database.)

Mode Line Configuration

Examples To apply the authentication method list called `CONSOLE` to the console port terminal line (asyn 0), use the following commands:

```
awplus# configure terminal
awplus(config)# line console 0
awplus(config-line)# login authentication CONSOLE
```

To reset user authentication configuration on all VTY lines, use the following commands:

```
awplus# configure terminal
awplus(config)# line vty 0 32
awplus(config-line)# no login authentication
```

Related Commands aaa authentication login
line

show debugging aaa

This command displays the current debugging status for AAA (Authentication, Authorization, Accounting).

Syntax `show debugging aaa`

Mode User Exec and Privileged Exec

Example To display the current debugging status of AAA, use the command:

```
awplus# show debug aaa
```

Output Figure 67-1: Example output from the **show debug aaa** command

```
AAA debugging status:
    Authentication debugging is on
    Accounting debugging is off
```

undebug aaa

This command applies the functionality of the no debug aaa command on page 67.26.

- RADIUS Server Configuration using Server Groups 68.17

Introduction

The main purpose of RADIUS (Remote Authentication Dial In User Service) is to enable the authentication of network users stored in a database on a server known as a RADIUS Server.

When users connect to the network, the switch the users connect to can challenge the users for authentication, and pass on the authentication to the RADIUS server to check. Based on the result of the check against the database, the RADIUS Server informs the switch whether or not to allow the connected user access to the network.

A RADIUS Server can do more than allow or deny access to the network. A RADIUS Server can send back parameters to the connected users, such as an IP address for the user, or a VLAN for the user, or a privilege level for a session. RADIUS also provides an accounting service. Switches can inform the RADIUS Server how long a user has been connected to the network, and how much traffic the user has sent and received while connected to the network.

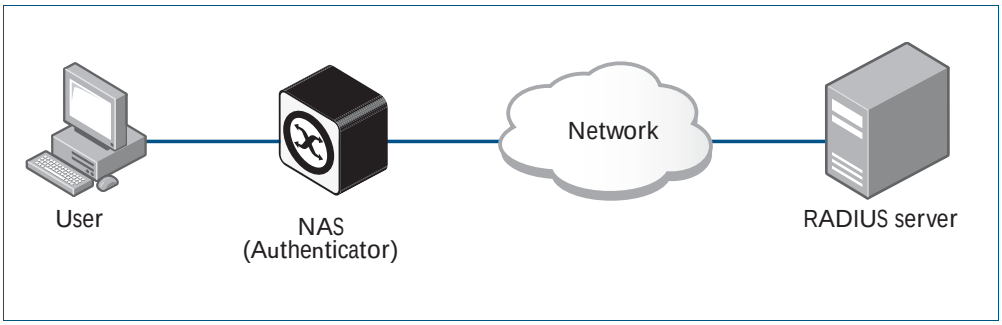
The original use for RADIUS was for the authentication of users dialling into an ISP (Internet Service Provider). A PPP (Point-to-Point Protocol) connection would be established between the remote client and the ISP's access switch. The ISP's access switch would receive the client's username and password using PAP (Password Authentication Protocol) or using CHAP (Challenge Handshake Authentication Protocol) and pass on the client's username and password to the RADIUS server to authenticate the client. The RADIUS Server's response to the authentication request would be sent back to the client as a PAP or CHAP allow or deny.

RADIUS has been adapted to network access authentication applications. Network access authentication using RADIUS follows a similar method to the PPP dial-up application for ISPs. For general network access authentication there is the RADIUS Server where the database of user authentication data is stored and a NAS (Network Access Server), which is the switch that user connects to first. The RADIUS Server and the NAS communicate with each other through exchanging attributes. Usernames and passwords are treated as attributes in RADIUS packets to and from a RADIUS Server and a NAS. The RADIUS Server is configured with a list of valid NASs that are allowed to send authentication requests to the RADIUS Server.

The RADIUS Server will not accept authentication requests from a NAS that is not on the list of valid NASs. Each NAS has a shared secret, which is a shared key with the RADIUS Server that is used to authenticate requests. The RADIUS Server has access to a list of user authentication data, stored within the RADIUS Server or accessed from another server.

Communication between the NAS and RADIUS Server uses the RADIUS protocol. The RADIUS protocol uses UDP packets. There are two UDP ports used as the destination port for RADIUS authentication packets (ports 1645 and 1812). Note that port 1812 is in more common use than port 1645 for authentication packets. UDP ports (ports 1646 and 1813) are used for RADIUS accounting separately from the ports used for RADIUS authentication.

Figure 68-1: Example showing a User to a NAS to a RADIUS Server network connection



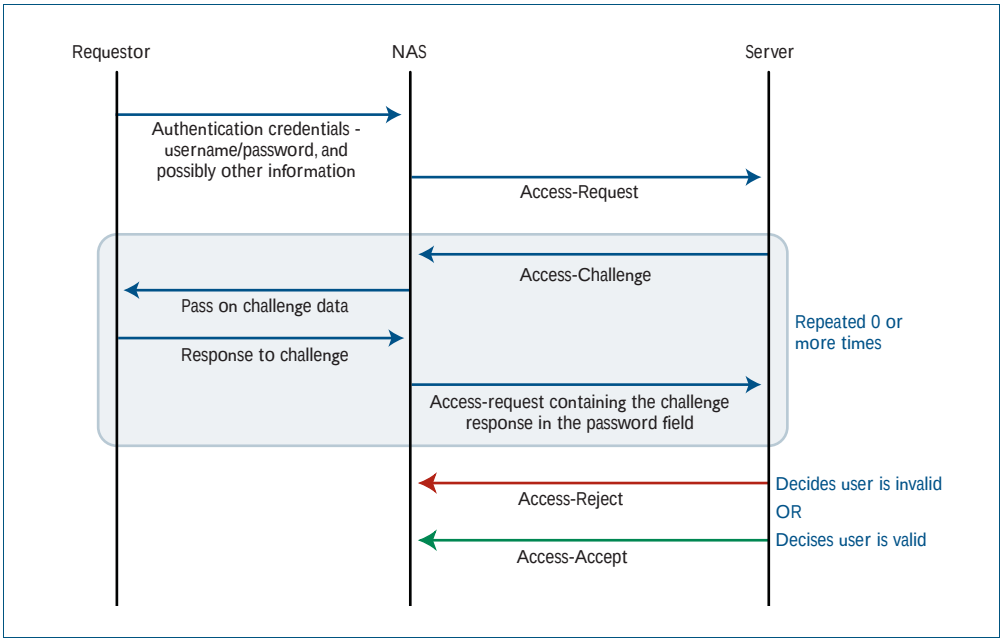
RADIUS Packets

The RADIUS RFCs define the RADIUS packet types and attributes. RADIUS authentication is defined by RFC2058, RFC2138, RFC2865, and RFC2868. RADIUS accounting is defined by RFC2059, RFC2139, RFC2866, and RFC2867. These RADIUS RFCs define over fifty attributes and six packets types (`Access-Request, Access-Accept, Access-Reject, Accounting-Request, Accounting-Response, Access-Challenge`).

A RADIUS exchange is initiated by the NAS when a user requests access to the NAS. The NAS obtains the user authentication data adds them into a RADIUS `Access-Request` packet type and sends the RADIUS `Access-Request` packet to the RADIUS Server.

- If a RADIUS Server has not been configured for authentication request from a NAS then it will silently discard an `Access-Request` packet from it.
- If the RADIUS Server accepts the request from the NAS it considers the authentication date provided in the `Access-Request` packet. The RADIUS Server may verify the user from its own database or it may connect to other servers to verify.
- If the RADIUS Server decides that the user is not allowed access to the NAS it responds to the NAS with an `Access-Reject` packet and the NAS will block the user.
- If the RADIUS Server decides that the user is valid but needs more information to verify that the user is not an imposter, it may send an `Access-Challenge` packet to the NAS that the NAS forwards to the user. The NAS forwards the user response to the `Access-Challenge` packet in an `Access-Request` packet to the RADIUS Server to accept or reject to allow or deny NAS user access.
- If the RADIUS Server rejects the user it sends an `Access-Reject` packet to the NAS.
- If the RADIUS Server accepts the user it sends an `Accept-Accept` packet to the NAS. The `Accept-Accept` packet to the NAS contains attributes that the NAS can apply.

Figure 68-2: Example showing an exchange from a Requestor to a NAS to a RADIUS Server



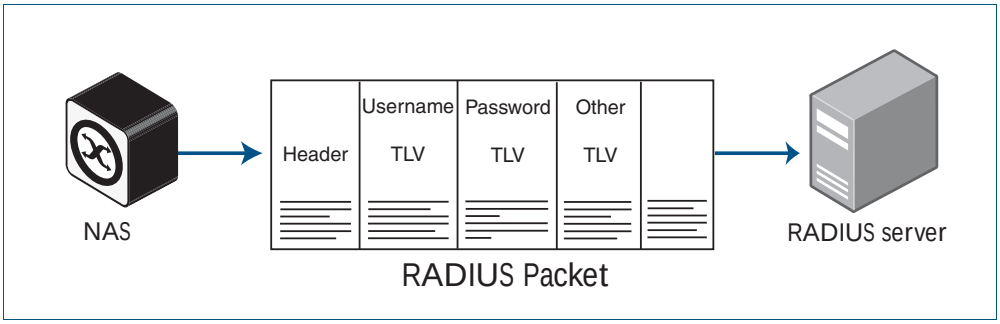
RADIUS Attributes

Each attribute is identified by its RFC-defined name, followed by its attribute ID in parenthesis.

- User-name(1)
  User-names are strings of at least three characters and have a maximum of 253 characters, which is the upper limit on all RADIUS attributes.
- User-password(2)
  User-passwords are encrypted using an MD5 hash of the password, the NAS's shared secret with the RADIUS Server, and a request authenticator value. User-passwords can either be used at the initial authentication attempt or in response to an Access-Challenge packet type from the RADIUS Server to the NAS.
- CHAP-password(3)
  CHAP-passwords are used if the NAS is using CHAP to authenticate the user, and doesn't receive the use the user's password but sends the CHAP response to the RADIUS Server instead. The CHAP password is an encrypted string that is an MD5 hash of the password and challenge value sent by the user.
- Framed-IP-Address(8)
  Used for dial-in user making PPP connections to the NAS who are dynamically allocated an IP address that they can use for the duration of their connect. The RADIUS Server sends the Framed-IP-Address to the NAS to allocate.
- Service-Type(6)
  Used when the NAS is authenticating a user who wants to open a management session on the NAS, and is sent by the RADIUS Server back to the NAS in an Access-Accept type packet to indicate the level of access the NAS gives a user. Service-Type(6) is mapped to a Privileged management session for AlliedWare Plus.
- NAS-Port-Type(61)
  Identifies the type of port on which the user is accessing the NAS. The NAS-Port-Type(61) attribute is sent by the NAS to the RADIUS Server in Access-Request type packet, so the RADIUS Server may use it to choose access type. For 802.1X sessions, the NAS-Port-Type sent by the NAS is Ethernet (15).
- 802.1X VLAN assignment uses:
  Tunnel-Type(64), Tunnel-Medium-Type(65), Tunnel-Private-Group-ID(81), Egress-VLANID(56), and Egress-VLAN-Name(58) attributes (specified in RFC4675 used to specify 802.1Q tagged and untagged VLAN assignments with LLDP-MED/Voice-VLAN).

Attributes are carried within RADIUS packets in the form of TLVs (Type Length Values). Every attribute has an attribute ID number in the Type field of the TLV. The Length field holds a one-byte number that represents then length of the TLV. The Value field holds the value of the attribute.

Figure 68-3: Example showing **TLVs** in a RADIUS Packet from a NAS to a RADIUS Server



RADIUS Security

RADIUS is used for network security and carries user authentication information, so can be a target for security attacks. To counter threats there are three elements to RADIUS security:

- Shared secret
- Authenticator
- Password Encryption

Shared Secret

Every NAS and server are configured with a pre-shared key, called the “shared secret”, which is a key string, with no particular format of at least 16 characters.

The protocol has no method for choosing and sharing the secret between the NAS and the server. The secret must be manually generated and separately configured on the NAS and on the server.

The shared secret itself never appears in any RADIUS packets. It is used as an input to the algorithms used for creating encrypted values that are carried in the packets.

Authenticator

The authenticator is a random 16-byte value generated by the NAS. The NAS creates a new authenticator value for each `Access-Request` that it sends.

The response packets that come back from the server contain a value called the Response Authenticator. This is a value that is created by performing an MD5 hash on a string that is created by concatenating the packet type identifier, Session ID, Authenticator sent in the request packet, Attribute fields in the packet, Shared secret that the server shares with the NAS to which it is responding.

When the NAS receives the response packet, it performs the same hash on the same values, and verifies that it comes up with the same result. If not, then it must assume that the response packet has been spoofed, and silently discards it.

Password Encryption

The value placed in the user-password TLV of an `Access-Request` packet is not simply an exact copy of the password sent from the requestor to the NAS.

The NAS concatenates together the shared secret and the authenticator that it has randomly generated for this request and then performs manipulations (MD5, XOR) on that concatenation, and the password to create the value to go into password TLV.

When the server validates the `Access-Request`, it retrieves the user’s password from the user credentials database, and performs the same manipulation upon that password. If the result matches the value in the user-password field of the `Access-Request`, then the password sent by the requestor is deemed to be correct.

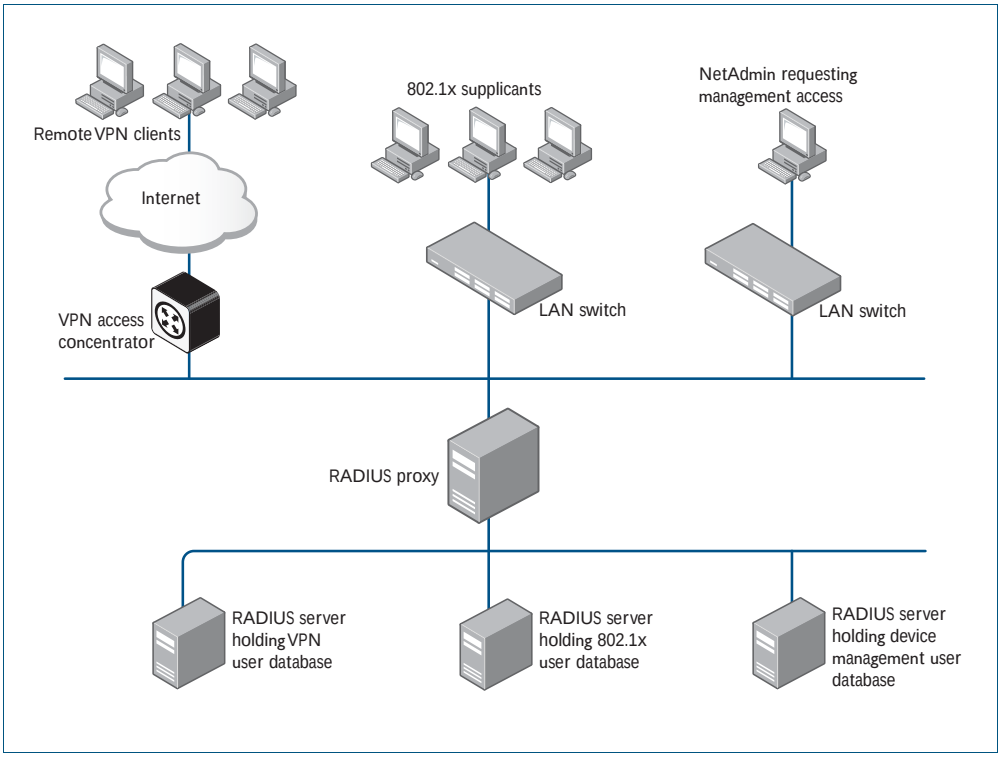
RADIUS Proxy

The user database, which user credentials sent to a RADIUS server are looked up in, may not reside on the RADIUS server itself. The external user database may reside on another RADIUS server, and the communication to that server uses RADIUS. In the case where a RADIUS server communicates with a NAS, but also acts as a client to another RADIUS server, is said to be acting as a RADIUS proxy.

There are a variety of situations where RADIUS proxy is useful. Multiple RADIUS servers could have been set up, holding user databases for different purposes such as Authentication, Switch management sessions, Authenticating VPN connections, and Authenticating 802.1X sessions.

But it is convenient for there to be just one address that all the NASs in the network use as their RADIUS server. That one RADIUS server that the NASs send their requests to, can act as a proxy for all the servers holding the different user databases.

Figure 68-4: Example showing RADIUS Proxy



RADIUS Accounting

There are only two types of RADIUS accounting packet: `Accounting-Request` and `Accounting-Response`.

The `Accounting-Request` packets are always sent from the NAS to the server. The `Accounting-Response` packets are always sent from the server to the NAS, and are effectively ACKs of the `Accounting-Request` packets.

The `Accounting-Request` packets always carry the attribute `Acct-Status-Type`. The most commonly used values of this attribute are:

- Start – which denotes a packet marking that a session is beginning
- Stop – which denotes a packet marking that a session is ending
- Interim update – packets sent periodically during the session to give update reports on the statistics that are being collected.

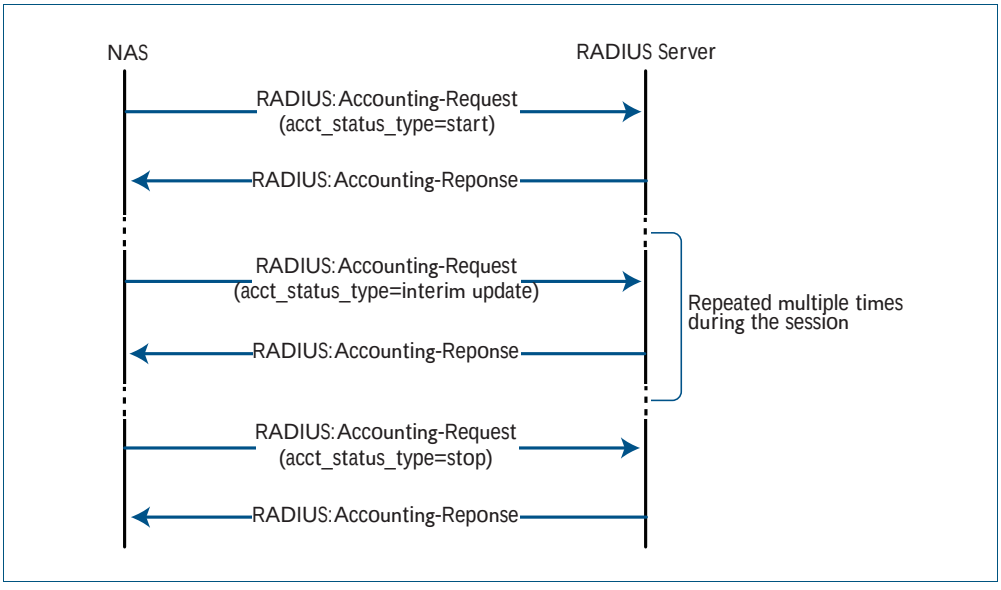
The statistics that can be exchanged in the session are:

- Input Octets
- Input Packets
- Output Octets
- Output Packets
- Session Duration

There is no requirement to exchange all these statistics – NAS implementations are at liberty to choose which statistics they will send. Each of these statistics has a corresponding attribute type. The attributes are sent in Interim-Update and Stop accounting request packets.

Each accounting session has a unique session ID, which is chosen by the NAS. The session ID is carried in an `Acct-Session-Id` attribute, that should be present in every packet involved in the session. The accounting packets typically do not use the same UDP port as the authentication packets. The default port for RADIUS accounting is 1813.

Figure 68-5: Example showing RADIUS Accounting between a NAS and a RADIUS Server



RADIUS Configuration

This section describes how to configure RADIUS with the available AAA commands. For a description of AAA commands, refer to the AAA Commands chapter. For a description of the RADIUS commands used, refer to the RADIUS Commands chapter.

RADIUS is often used in a variety of networks that need high security while maintaining access for remote users. RADIUS is suitable for the following networks that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers from several vendors use a single RADIUS server-based security database.
- Networks in which a user may access a single service. Using RADIUS, you can control user access to a single host, or to a single utility such as Telnet.
- Networks that require accounting. You can use RADIUS accounting independent of RADIUS authentication. The RADIUS accounting functions allow data to be sent at the start and end of services, indicating the amount of resources (time, packets, bytes) used.

Switch Configuration Tasks

To configure RADIUS on your switch or access server, you must perform the following tasks:

- Use the aaa authentication command to define method lists for RADIUS authentication. For information about this command, refer to the AAA Commands chapter.
- Use authentication commands to enable the defined method lists to be used. For more information, refer to the Authentication Commands chapter.

The following configuration tasks are optional:

- You can use the aaa group server command to group selected RADIUS hosts for specific services. For detailed information about this command, refer to the AAA Server Groups Configuration section in this chapter and refer to the AAA Commands chapter.
- You can use the aaa accounting login command to enable accounting for RADIUS connections. For information about this command, refer to the AAA Commands chapter.

This section describes how to set up RADIUS for authentication and accounting on your network, and includes the following sections:

- Switch to RADIUS Server Communication (Required)
- Configuring AAA Server Groups (Optional)
- Configuring AAA Server Groups with Deadtime (Optional)
- Specifying RADIUS Authentication
- Specifying RADIUS Accounting (Optional)

For RADIUS configuration examples using the commands in this chapter, refer to the section RADIUS Configuration Examples at the end of this chapter.

Switch to RADIUS Server Communication

The RADIUS host is normally a multiuser system running RADIUS server software from a software provider. Switch to RADIUS server communication has several components:

- Host name or IP address
- Authentication destination port
- Accounting destination port
- Timeout period
- Retransmission value
- Key string

RADIUS security servers are identified on the basis of their host name or IP address, host name and specific UDP port numbers, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address.

A RADIUS server and a switch use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS using the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text string that it shares with the switch, which you can specify using the key parameter in the radius-server host command.

The timeout, retransmission, and encryption key values are configurable globally for all RADIUS servers, on a per-server basis, or in some combination of global and per-server settings. To apply these settings globally to all RADIUS servers communicating with the switch, use the three global commands: radius-server timeout, radius-server retransmit, and radius-server key. To apply these values on a specific RADIUS server, use the radius-server host command.

Note

You can configure both global and per-server timeout, retransmission, and key value commands simultaneously on the same Network Access Server.

If both global and per-server functions are configured on a switch, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands.

To configure per-server RADIUS server communication, use the following command in the Global Configuration mode:

Mode and Command	Command Purpose

`awplus(config)#`
`radius-server host`
`{<hostname>|`
`<ip-address>}`
`[auth-port <port-number>]`
`[acct-port <port-number>]`
`[timeout <seconds>]`
`[retransmit <retries>]`
`[key <string>]`
	Specifies the IP address or host name of the remote RADIUS server host and assigns authentication and accounting destination UDP port numbers.
	Use the `auth-port <port-number>` option to configure a specific UDP port on this RADIUS server to be used solely for authentication.
	Use the `acct-port <port-number>` option to configure a specific UDP port on this RADIUS server to be used solely for accounting.
	To configure the network access server to recognize more than one host entry associated with a single IP address, simply repeat this command as many times as necessary, making sure that each UDP port number is different.
	Set the timeout, retransmit, and encryption key values to use with the specific RADIUS host. If no timeout is set, the global value is used; otherwise, enter a value in the range 1 to 1000.
	If no retransmit value is set, the global value is used; otherwise enter a value in the range 1 to 1000. If no key string is specified, the global value is used.

To configure global communication settings between the switch and a RADIUS server, use the following radius-server commands in the Global Configuration mode:

Mode and Command	Command Purpose
`awplus(config)#` `radius-server key <key>`	Specifies the shared secret text string used between the switch and a RADIUS server (no default is set).

`awplus(config)#`
`radius-server retransmit`
`<retries>`
	Specifies how many times the switch transmits each RADIUS request to the RADIUS server before giving up (the default is 3).

`awplus(config)#`
`radius-server timeout`
`<seconds>`
	Specifies for how many seconds a switch waits for a reply to a RADIUS request before retransmitting the request.

`awplus(config)#`
`radius-server deadtime`
`<minutes>`
	Specifies for how many minutes a RADIUS server that is not responding to authentication requests is passed over by requests for RADIUS authentication.

AAA Server Groups Configuration

Configuring the switch to use AAA server groups provides a way to group existing server hosts. This allows you to select a subset of the configured server hosts and use them for a particular service. A server group is used in conjunction with a global server-host list. The server group lists the IP addresses of the selected server hosts.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service.

To define a server host with a server group name, enter the following commands in the Global Configuration mode. The listed RADIUS server must exist in the Global Configuration mode:

Mode and Command	Command Purpose
awplus(config)# radius-server host {*<hostname>*| *<ip-address>*} [auth-port *<port-number>*] [acct-port *<port-number>*] [timeout *<seconds>*] [retransmit *<retries>*] [key *<string>*]	Specifies and defines the IP address of the server host before configuring the AAA server-group. Refer to the section Switch to RADIUS Server Communication of this chapter for more information on the radius-server host command.
awplus(config-if)# aaa group server *<group-name>*	Defines the AAA server group with a group name. This command puts the switch in server group sub configuration mode.
awplus(config-sg)# server {*<hostname>*|*<ip-address>*} [auth-port *<port-number>*] [acct-port *<port-number>*]	Associates a particular RADIUS server with the defined server group. Each security server is identified by its IP address and UDP port number. Repeat this step for each RADIUS server in the AAA server group. Each server in the group must be defined previously using the radius-server host command.

Configuring AAA Server Groups with Deadtime

After you have configured a server host with a server name, you can use the deadtime (RADIUS server group) command to configure each server per server group. Configuring deadtime within a server group allows you to direct AAA traffic to separate groups of servers that have different operational characteristics.

Configuring deadtime is no longer limited to a global configuration. A separate timer has been attached to each server host in every server group. When a server is found to be unresponsive after numerous retransmissions and time-outs, the server is assumed to be dead. The timers attached to each server host in all server groups are triggered. In essence, the timers are checked and subsequent requests to a server, once it is assumed to be dead, are directed to alternate servers, if configured. When the network access server receives a reply from the server, it checks and stops all configured timers, if running, for that server in all server groups.

If the timer has expired, only the server to which the timer is attached is assumed to be alive. This becomes the only server that can be tried for later AAA requests using the server groups to which the timer belongs.

Note

Since one server has different timers and may have different deadtime values configured in the server groups, the same server may in the future have different states, dead and alive, at the same time. To change the state of a server, you must start and stop all configured timers in all server groups.

The size of the server group will be increased because of the addition of new timers and the deadtime attribute. The overall impact of the structure depends on the number and size of the server groups and how the servers are shared among server groups in a specific configuration.

To configure deadtime within a server group, use the following commands beginning in the Global Configuration mode:

Mode and Command	Command Purpose
`awplus(config)# aaa group server radius group1`	Defines a RADIUS type server group.
`awplus(config-sg)# deadtime 1`	Configures and defines a deadtime value in minutes.
`awplus(config-sg)# exit`	Exits server group configuration mode.

Specifying RADIUS Authentication

After you have identified the RADIUS server and defined the RADIUS authentication key, you must define method lists for RADIUS authentication. Because RADIUS authentication is facilitated through AAA, you must enter the aaa authentication login command, specifying RADIUS as the authentication method. For detailed aaa authentication login command information, refer to the AAA Commands chapter.

Specifying RADIUS Accounting

The AAA accounting feature enables you to track the services users are accessing as well as the amount of network resources they are consuming. Because RADIUS accounting is facilitated through AAA, you must issue the aaa accounting login command, specifying RADIUS as the accounting method. For detailed aaa accounting login command information, refer to the AAA Commands chapter.

Monitoring and Maintaining RADIUS

To monitor and maintain RADIUS, use the following commands in Privileged Exec mode:

Mode and Command	Command Purpose
`awplus#` `debug radius`	Displays information associated with RADIUS. For detailed debug radius command information, refer to the RADIUS Commands chapter.
`awplus#` `show radius statistics`	Displays the RADIUS statistics for accounting and authentication packets. For detailed show radius statistics command information, refer to the RADIUS Commands chapter.

RADIUS Configuration Examples

The following sections provide RADIUS configuration examples:

- RADIUS Authentication
- Single RADIUS Server Configuration
- Multiple RADIUS Server Configuration
- RADIUS Server Group Configuration
- RADIUS Server Configuration using Server Groups

RADIUS Authentication

Example The following example shows how to configure the switch to authenticate using RADIUS:

Figure 68-6: Sample RADIUS Authentication to configure the switch to authenticate users

```
!
radius-server host 172.10.10.1
radius-server key radiuspass
username newuser password newpass
aaa authentication login admin
!
```

The lines in this example RADIUS authentication and accounting configuration are defined as follows:

- The radius-server host command defines the IP address of the RADIUS server host.
- The radius-server key command defines the shared secret text string between the network access server and the RADIUS server host.
- The aaa authentication login command defines a method list named admin for login authentication.

Example The following example shows how to configure the switch to authenticate logins using RADIUS:

Figure 68-7: Sample RADIUS Authentication to authenticate logins

```
!
aaa authentication login radius-login group radius
!
```

This sample RADIUS authentication configuration is defined as follows:

- The aaa authentication login radius-login group radius command configures the switch to use RADIUS for authentication at the login prompt.

Example The following example shows how to configure the authentication method to verify a username and password at login. In this example, if a username is entered at the username prompt, that username is used for authentication.

Figure 68-8: Sample RADIUS Authentication to verify a username and password

```
!
aaa authentication login default group radius
radius-server host 172.10.10.1 auth-port 1812 acct-port 1813
!
```

The lines in this sample RADIUS authentication configuration are defined as follows:

- The aaa authentication login default group radius command specifies that the username and password are verified by RADIUS.
- The radius-server host 172.10.10.1 auth-port 1812 acct-port 1813 command specifies the IP address of the RADIUS server host, the UDP destination port for authentication requests, and the UDP destination port for accounting requests.

Single RADIUS Server Configuration

Example The following example shows how to configure server-specific timeout, retransmit, and key values for the RADIUS server with IP address 172.2.2.2:

Figure 68-9: Single RADIUS Server sample configuration

```
!
radius-server host 172.2.2.2 timeout 5 retransmit 5 key 10
!
```

Multiple RADIUS Server Configuration

Example The following example shows how to configure two RADIUS servers with specific timeout, retransmit, and key values. The radius-server retransmit command changes the global retransmission value to 4 for all RADIUS servers. The radius-server host command configures specific timeout, retransmission, and key values for the RADIUS server hosts with IP addresses `172.2.2.2` and `172.1.1.1`

Figure 68-10: Multiple RADIUS Server sample configuration

```
!
! Enable and configure radius authentication and accounting
! services on the switch:
!
aaa authentication login default group radius
aaa accounting default start-stop group radius
!
! Change the retransmission value for all RADIUS servers:
!
radius-server retransmit 4
!
! Configure per-server specific timeout, retransmission, and
! key values. Change the default auth-port and acct-port
! values.
!
radius-server host 172.2.2.2 auth-port 1645 acct-port 1646
timeout 3 retransmit 3 key radkey
!
! Configure per-server specific timeout and key values. This
! server uses the global retransmission value.
!
radius-server host 172.1.1.1 timeout 6 key rad123
!
```

RADIUS Server Group Configuration

Example The following example shows how to create server group `group2` with three RADIUS server members, each with the same IP address but with unique authentication and accounting ports:

Figure 68-11: RADIUS Server Group sample configuration using the same IP address

```
!
aaa group server radius group2
  server 172.1.1.1 auth-port 1645 acct-port 1646
  server 172.1.1.1 auth-port 1812 acct-port 1813
  server 172.1.1.1 auth-port 2000 acct-port 2001
!
```

RADIUS Server Configuration using Server Groups

The following example shows how to configure the network access server to recognize two different RADIUS server groups.

One of these groups, `group1`, has two different host entries on the same RADIUS server configured for the same services. The second host entry configured acts as fail over backup to the first one. Each group is individually configured for `deadtime`; `deadtime` for `group1` is one minute, and `deadtime` for `group2` is two minutes.

Figure 68-12: Multiple RADIUS Servers using Server Groups sample configuration

```
!
! The following command configures default RADIUS parameters:
!
aaa authentication login default group group1
!
! The following commands define the group1 RADIUS server group
! and associate servers with it and configures a deadtime of
! one minute:
!
aaa group server radius group1
  server 172.1.1.1 auth-port 1645 acct-port 1646
  server 172.2.2.2 auth-port 1812 acct-port 1813
  deadtime 1
!
! The following commands define the group2 RADIUS server group
! and associate servers with it and configures a deadtime of
! two minutes:
!
aaa group server radius group2
  server 172.2.2.2 auth-port 1812 acct-port 1813
  server 172.3.3.3 auth-port 2000 acct-port 2001
  deadtime 2
!
! The following commands configure the RADIUS attributes
! for each host entry associated with one of the defined
! server groups:
!
radius-server host 172.1.1.1 auth-port 1645 acct-port 1646
radius-server host 172.2.2.2 auth-port 1812 acct-port 1813
radius-server host 172.3.3.3 auth-port 2000 acct-port 2001
!
```

Chapter 69: RADIUS Commands

Command List 69.2
deadtime (RADIUS server group) 69.2
debug radius 69.3
ip radius source-interface 69.4
radius-server deadtime 69.5
radius-server host 69.6
radius-server key 69.9
radius-server retransmit 69.10
radius-server timeout 69.11
server (Server Group) 69.13
show debugging radius 69.15
show radius 69.16
show radius statistics 69.18
undebug radius 69.18

Command List

This chapter provides an alphabetical reference for commands used to configure the device to use RADIUS servers.

deadtime (RADIUS server group)

Use this command to configure the deadtime parameter for the RADIUS server group. This command overrides the global dead-time configured by the radius-server deadtime command on page 69.5. The configured deadtime is the time period in minutes to skip a RADIUS server for authentication or accounting requests if the server is “dead”. Note that a RADIUS server is considered “dead” if there is no response from the server within a defined time period.

Use the no variant of this command to reset the deadtime configured for the RADIUS server group. If the global deadtime for RADIUS server is configured the value will be used for the servers in the group. The global deadtime for the RADIUS server is set to 0 minutes by default.

Syntax

```
deadtime <0-1440>
no deadtime
```

Parameter	Description
<0-1440>	Amount of time in minutes.

Default The deadtime is set to 0 minutes by default.

Mode Server Group Configuration

Usage If the RADIUS server does not respond to a request packet, the packet is retransmitted the number of times configured for the retransmit parameter (after waiting for a timeout period to expire). The server is then marked “dead”, and the time is recorded. The deadtime parameter configures the amount of time to skip a dead server; if a server is dead, no request message is sent to the server for the deadtime period.

Examples To configure the deadtime for 5 minutes for the RADIUS server group "GROUP1", use the command:

```
awplus(config)# aaa group server radius GROUP1
awplus(config-sg)# server 192.168.1.1
awplus(config-sg)# deadtime 5
```

To remove the deadtime configured for the RADIUS server group "GROUP1", use the command:

```
awplus(config)# aaa group server radius GROUP1
awplus(config-sg)# no deadtime
```

Related Commands aaa group server
radius-server deadtime

debug radius

This command enables RADIUS debugging. If no option is specified, all debugging options are enabled.

Use the no variant of this command to disable RADIUS debugging. If no option is specified, all debugging options are disabled.

Syntax

```
debug radius [packet|event|all]
no debug radius [packet|event|all]
```

Parameter	Description
`packet`	Debugging for RADIUS packets is enabled or disabled.
`event`	Debugging for RADIUS events is enabled or disabled.
`all`	Enable or disable all debugging options.

Default RADIUS debugging is disabled by default.

Mode Privileged Exec

Examples To enable debugging for RADIUS packets, use the command:

```
awplus#  debug radius packet
```

To enable debugging for RADIUS events, use the command:

```
awplus#  debug radius event
```

To disable debugging for RADIUS packets, use the command:

```
awplus# no debug radius packet
```

To disable debugging for RADIUS events, use the command:

```
awplus# no debug radius event
```

Related Commands show debugging radius
undebug radius

ip radius source-interface

This command configures the source IP address of every outgoing RADIUS packet to use a specific IP address or the IP address of a specific interface. If the specified interface is down or there is no IP address on the interface, then the source IP address of outgoing RADIUS packets depends on the interface the packets leave.

Use the no variant of this command to remove the source interface configuration. The source IP address in outgoing RADIUS packets will be the IP address of the interface from which the packets are sent.

Syntax

```
ip radius source-interface {<interface>|<ip-address>}
no ip radius source-interface
```

Parameter	Description
<interface>	Interface name.
<ip-address>	IP address in the dotted decimal format A.B.C.D.

Default Source IP address of outgoing RADIUS packets depends on the interface the packets leave.

Mode Global Configuration

Examples To configure all outgoing RADIUS packets to use the IP address of the interface "vlan1" for the source IP address, use the following commands:

```
awplus# configure terminal
awplus(config)# ip radius source-interface vlan1
```

To configure the source IP address of all outgoing RADIUS packets to use 192.168.1.10, use the following commands:

```
awplus# configure terminal
awplus(config)# ip radius source-interface 192.168.1.10
```

To reset the source interface configuration for all outgoing RADIUS packets, use the following commands:

```
awplus# configure terminal
awplus(config)# no ip radius source-interface
```

Related Commands radius-server host
show radius statistics

radius-server deadtime

Use this command to specify the global deadtime for all RADIUS servers. If a RADIUS server is considered dead, it is skipped for the specified deadtime. This command specifies for how many minutes a RADIUS server that is not responding to authentication requests is passed over by requests for RADIUS authentication.

Use the no variant of this command to reset the global deadtime to the default of 0 seconds, so that RADIUS servers are not skipped even if they are dead.

Syntax

```
radius-server deadtime <minutes>
no radius-server deadtime
```

Parameter	Description
<minutes>	RADIUS server deadtime in minutes in the range 0 to 1440 (24 hours).

Default The default RADIUS deadtime configured on the system is 0 seconds.

Mode Global Configuration

Usage The RADIUS client considers a RADIUS server to be dead if it fails to respond to a request after it has been retransmitted as often as specified globally by the radius-server retransmit command or for the server by the radius-server host command. To improve RADIUS response times when some servers may be unavailable, set a deadtime to skip dead servers.

Examples To set the dead time of the RADIUS server to 60 minutes, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server deadtime 60
```

To disable the dead time of the RADIUS server, use the following commands:

```
awplus# configure terminal
awplus(config)# no radius-server deadtime
```

Related Commands

deadtime (RADIUS server group)
radius-server host
radius-server retransmit
show radius statistics

radius-server host

Use this command to specify a remote RADIUS server host for authentication or accounting, and to set server-specific parameters. The parameters specified with this command override the corresponding global parameters for RADIUS servers. This command specifies the IP address or host name of the remote RADIUS server host and assigns authentication and accounting destination UDP port numbers.

This command adds the RADIUS server address and sets parameters to the RADIUS server. The RADIUS server is added to the running configuration after you issue this command. If parameters are not set using this command then common system settings are applied.

Use the no variant of this command to remove the specified server host as a RADIUS authentication and/or accounting server and set the destination port to the default RADIUS server port number (1812).

Syntax

```
radius-server host {<host-name>|<ip-address>} [acct-port <0-65535>]
   [auth-port <0-65535>] [key <key-string>] [retransmit <0-100>]
   [timeout <1-1000>]

no radius-server host {<host-name>|<ip-address>}
   [acct-port <0-65535>] [auth-port <0-65535>]
```

Parameter	Description
<host-name>	Server host name. The DNS name of the RADIUS server host.
<ip-address>	The IP address of the RADIUS server host.
acct-port	Accounting port. Specifies the UDP destination port for RADIUS accounting requests. If 0 is specified, the server is not used for accounting. The default UDP port for accounting is 1813.
<0-65535>	UDP port number (Accounting port number is set to 1813 by default) Specifies the UDP destination port for RADIUS accounting requests. If 0 is specified, the host is not used for accounting.
auth-port	Authentication port. Specifies the UDP destination port for RADIUS authentication requests. If 0 is specified, the server is not used for authentication. The default UDP port for authentication is 1812.
<0-65535>	UDP port number (Authentication port number is set to 1812 by default) Specifies the UDP destination port for RADIUS authentication requests. If 0 is specified, the host is not used for authentication.
timeout	Specifies the amount of time to wait for a response from the server. If this parameter is not specified the global value configured by the radius-server timeout command is used.
<1-1000>	Time in seconds to wait for a server reply (timeout is set to 5 seconds by default) The time interval (in seconds) to wait for the RADIUS server to reply before retransmitting a request or considering the server dead. This setting overrides the global value set by the radius-server timeout command. If no timeout value is specified for this server, the global value is used.

Parameter(cont.)	Description(cont.)
`retransmit`	Specifies the number of retries before skip to the next server. If this parameter is not specified the global value configured by the radius-server retransmit command is used.
<0-100>	Maximum number of retries (maximum number of retries is set to 3 by default) The maximum number of times to resend a RADIUS request to the server, if it does not respond within the timeout interval, before considering it dead and skipping to the next RADIUS server. This setting overrides the global setting of the radius-server retransmit command. If no retransmit value is specified, the global value is used.
`key`	Set shared secret key with RADIUS servers
`<key-string>`	Shared key string applied Specifies the shared secret authentication or encryption key for all RADIUS communications between this device and the RADIUS server. This key must match the encryption used on the RADIUS daemon. All leading spaces are ignored, but spaces within and at the end of the string are used. If spaces are used in the string, do not enclose the string in quotation marks unless the quotation marks themselves are part of the key. This setting overrides the global setting of the radius-server key command. If no key value is specified, the global value is used.

Default The RADIUS client address is not configured (null) by default. No RADIUS server is configured.

Mode Global Configuration

Usage Multiple radius-server host commands can be used to specify multiple hosts. The software searches for hosts in the order they are specified. If no host-specific timeout, retransmit, or key values are specified, the global values apply to that host. If there are multiple RADIUS servers for this client, use this command multiple times—once to specify each server.

If you specify a host without specifying the auth port or the acct port, it will by default be configured for both authentication and accounting, using the default UDP ports. To set a host to be a RADIUS server for authentication requests only, set the acct-port parameter to 0; to set the host to be a RADIUS server for accounting requests only, set the auth-port parameter to 0.

A RADIUS server is identified by IP address, authentication port and accounting port. A single host can be configured multiple times with different authentication or accounting ports. All the RADIUS servers configured with this command are included in the predefined RADIUS server group radius, which may be used by AAA authentication, authorization and accounting commands. The client transmits (and retransmits, according to the retransmit and timeout parameters) RADIUS authentication or accounting requests to the servers in the order you specify them, until it gets a response.

Examples To add the RADIUS server `10.0.0.20`, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server host 10.0.0.20
```

To set the secret key to allied on the RADIUS server `10.0.0.20`, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server host 10.0.0.20 key allied
```

To delete the RADIUS server `10.0.0.20`, use the following commands:

```
awplus# configure terminal
awplus(config)# no radius-server host 10.0.0.20
```

To configure `rad1.company.com` for authentication only, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server host rad1.company.com
acct-port 0
```

To remove the RADIUS server `rad1.company.com` configured for authentication only, use the following commands:

```
awplus# configure terminal
awplus(config)# no radius-server host rad1.company.com
acct-port 0
```

To configure `rad2.company.com` for accounting only, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server host rad2.company.com
auth-port 0
```

To configure 192.168.1.1 with authentication port 1000, accounting port 1001 and retransmit count 5, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server host 192.168.1.1 auth-port 1000
acct-port 1001 retransmit 5
```

Related Commands

radius-server key
radius-server retransmit
radius-server timeout
show radius statistics

radius-server key

This command sets a global secret key for RADIUS authentication on the switch. The shared secret text string is used for RADIUS authentication between the switch and a RADIUS server.

Note that if no secret key is explicitly specified for a RADIUS server, the global secret key will be used for the shared secret for the server.

Use the no variant of this command to reset the secret key to the default (null).

Syntax

```
radius-server key <key>
no radius-server key
```

Parameter	Description
<key>	Shared secret among radius server and 802.1X client.

Default The RADIUS server secret key on the system is not set by default (null).

Mode Global Configuration

Usage Use this command to set the global secret key shared between this client and its RADIUS servers. If no secret key is specified for a particular RADIUS server using the radius-server host command, this global key is used.

After enabling AAA authentication with the aaa authentication login command, set the authentication and encryption key using the radius-server key command so the key entered matches the key used on the RADIUS server.

Examples To set the global secret key to allied for RADIUS server, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server key allied
```

To set the global secret key to secret for RADIUS server, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server key secret
```

To delete the global secret key for RADIUS server, use the following commands:

```
awplus# configure terminal
awplus(config)# no radius-server key
```

Related Commands radius-server host
show radius statistics

radius-server retransmit

This command sets the retransmit counter to use RADIUS authentication on the switch. This command specifies how many times the switch transmits each RADIUS request to the RADIUS server before giving up.

This command configures the retransmit parameter for RADIUS servers globally. If the retransmit parameter is not specified for a RADIUS server by the radius-server host command then the global configuration set by this command is used for the server instead.

Use the no variant of this command to reset the re-transmit counter to the default (3).

Syntax

```
radius-server retransmit <retries>
no radius-server retransmit
```

Parameter	Description
<retries>	RADIUS server retries in the range <0-100> The number of times a request is resent to a RADIUS server that does not respond, before the server is considered dead and the next server is tried. If no retransmit value is specified for a particular RADIUS server using the radius-server host command, this global value is used.

Default The default RADIUS retransmit count on the switch is 3.

Mode Global Configuration

Examples To set the RADIUS retransmit count to 1, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server retransmit 1
```

To set the RADIUS retransmit count to the default (3), use the following commands:

```
awplus# configure terminal
awplus(config)# no radius-server retransmit
```

To configure the RADIUS retransmit count globally with 5, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server retransmit 5
```

To disable retransmission of requests to a RADIUS server, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server retransmit 0
```

Related Commands

radius-server deadtime
radius-server host
show radius statistics

radius-server timeout

Use this command to specify the RADIUS global timeout value. This is how long the device waits for a reply to a RADIUS request before retransmitting the request, or considering the server to be dead. If no timeout is specified for the particular RADIUS server by the radius-server host command, it uses this global timeout value.

Note that this command configures the timeout parameter for RADIUS servers globally.

The no variant of this command resets the transmit timeout to the default (5 seconds).

Syntax

```
radius-server timeout <seconds>
no radius-server timeout
```

Parameter	Description
<seconds>	RADIUS server timeout in seconds in the range 1 to 1000. The global time in seconds to wait for a RADIUS server to reply to a request before retransmitting the request, or considering the server to be dead (depending on the radius-server retransmit command).

Default The default RADIUS transmit timeout on the system is 5 seconds.

Mode Global Configuration

Examples To globally set the device to wait 20 seconds before retransmitting a RADIUS request to unresponsive RADIUS servers, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server timeout 20
```

To set the RADIUS timeout parameter to 1 second, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server timeout 1
```

To set the RADIUS timeout parameter to the default (5 seconds), use the following commands:

```
awplus# configure terminal
awplus(config)# no radius-server timeout
```

To configure the RADIUS server timeout period globally with 3 seconds, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server timeout 3
```

To reset the global timeout period for RADIUS servers to the default, use the following command:

```
awplus# configure terminal
awplus(config)# no radius-server timeout
```

server (Server Group)

This command adds a RADIUS server to a server group in Server-Group Configuration mode. The RADIUS server should be configured by the radius-server host command.

The server is appended to the server list of the group and the order of configuration determines the precedence of servers. If the server exists in the server group already, it will be removed before added as a new server.

The server is identified by IP address and authentication and accounting UDP port numbers. So a RADIUS server can have multiple entries in a group with different authentication and/or accounting UDP ports. The auth-port specifies the UDP destination port for authentication requests to the server. To disable authentication for the server, set `auth-port` to 0. If the authentication port is missing, the default port number is 1812. The acct-port specifies the UDP destination port for accounting requests to the server. To disable accounting for the server, set `acct-port` to 0. If the accounting port is missing, the default port number is 1812.

Use the no variant of this command to remove a RADIUS server from the server group.

Syntax

```
server {<hostname>|<ip-address>}
    [auth-port <0-65535>][acct-port <0-65535>]

no server {<hostname>|<ip-address>}
    [auth-port <0-65535>][acct-port <0-65535>]
```

Parameter	Description
`<hostname>`	Server host name
`<ip-address>`	Server IP address The server is identified by IP address, authentication and accounting UDP port numbers. So a RADIUS server can have multiple entries in a group with different authentication and/or accounting UDP ports.
`auth-port`	Authentication port The auth-port specifies the UDP destination port for authentication requests to the server. To disable authentication for the server, set auth-port to 0. If the authentication port is missing, the default port number is 1812.
`<0-65535>`	UDP port number (default: 1812)
`acct-port`	Accounting port The acct-port specifies the UDP destination port for accounting requests to the server. To disable accounting for the server, set acct-port to 0. If the accounting port is missing, the default port number is 1813.
`<0-65535>`	UDP port number (default: 1813)

Default The default Authentication port number is 1812 and the default Accounting port number is 1813.

Mode Server Group Configuration

Usage The RADIUS server to be added must be configured by the radius-server host command. In order to add or remove a server, the auth-port and acct-port parameters in this command must be the same as the corresponding parameters in the radius-server host command.

Examples To create a RADIUS server group RAD_AUTH1 for authentication, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa group server radius RAD_AUTH1
awplus(config-sg)# server 192.168.1.1 acct-port 0
awplus(config-sg)# server 192.168.2.1 auth-port 1000
acct-port 0
```

To create a RADIUS server group RAD_ACCT1 for accounting, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa group server radius RAD_ACCT1
awplus(config-sg)# server 192.168.2.1 auth-port 0
acct-port 1001
awplus(config-sg)# server 192.168.3.1 auth-port 0
```

To remove server 192.168.3.1 from the existing server group GROUP1, use the following commands:

```
awplus# configure terminal
awplus(config)# aaa group server radius GROUP1
awplus(config-sg)# no server 192.168.3.1
```

Related Commands
aaa accounting auth-mac default
aaa accounting auth-web default
aaa accounting dot1x
aaa accounting login
aaa authentication auth-mac
aaa authentication auth-web
aaa authentication login
aaa group server
radius-server host

show debugging radius

This command displays the current debugging status for the RADIUS servers.

Syntax `show debugging radius`

Mode User Exec and Privileged Exec

Example To display the current debugging status of RADIUS servers, use the command:

```
awplus# show debugging radius
```

Output Figure 69-1: Example output from the **show debugging radius** command

```
RADIUS debugging status:
RADIUS event debugging is off
RADIUS packet debugging is off
```

show radius

This command displays the current RADIUS server configuration and status.

Syntax `show radius`

Mode User Exec and Privileged Exec

Example To display the current status of RADIUS servers, use the command:

```
awplus# show radius
```

Output Figure 69-2: Example output from the **show radius** command showing RADIUS servers

```
RADIUS Global Configuration
Source Interface : not configured
Secret Key : secret
Timeout : 5 sec
Retransmit Count : 3
Deadtime : 20 min
Server Host : 192.168.1.10
Authentication Port : 1812
Accounting Port : 1813
Secret Key : secret
Timeout : 3 sec
Retransmit Count : 2
Server Host : 192.168.1.11
Authentication Port : 1812
Accounting Port : not configured
Server Name/Auth Acct Auth Acct
IP Address Port Port Status Status
-------------------------------------------------------------
192.168.1.10 1812 1813 Alive Alive
192.168.1.11 1812 N/A Alive N/A
```

Example See the sample output below showing RADIUS client status and RADIUS configuration:

```
awplus# show radius
```

Output Figure 69-3: Example output from the **show radius** command showing RADIUS client status

```
RADIUS global interface name: awplus
Secret key:
Timeout: 5
Retransmit count: 3
Deadtime: 0

Server Address: 150.87.18.89
Auth destination port: 1812
Accounting port: 1813
Secret key: swg
Timeout: 5
Retransmit count: 3
Deadtime: 0show radius local-server group
```

Output Parameter	Meaning	
Source Interface	The interface name or IP address to be used for the source address of all outgoing RADIUS packets.	
Secret Key	A shared secret key to a radius server.	
Timeout	A time interval in seconds.	
Retransmit Count	The number of retry count if a RADIUS server does not response.	
Deadtime	A time interval in minutes to mark a RADIUS server as “dead”.	
Interim-Update	A time interval in minutes to send Interim-Update Accounting report.	
Group Deadtime	The deadtime configured for RADIUS servers within a server group.	
Server Host	The RADIUS server hostname or IP address.	
Authentication Port	The destination UDP port for RADIUS authentication requests.	
Accounting Port	The destination UDP port for RADIUS accounting requests.	
Auth Status	The status of the authentication port. The status ("dead", “error”, or "alive") of the RADIUS authentication server and, if dead, how long it has been dead for.	
	Alive	The server is alive.
	Error	The server is not responding.
	Dead	The server is detected as dead and it will not be used for deadtime period. The time displayed in the output shows the server is in dead status for that amount of time.
	Unknown	The server is never used or the status is unknown.
Acct Status	The status of the accounting port. The status ("dead", “error”, or "alive") of the RADIUS accounting server and, if dead, how long it has been dead for.	

show radius statistics

This command shows the RADIUS client statistics for the switch.

Syntax `show radius statistics`

Mode User Exec and Privileged Exec

Example See the sample output below showing RADIUS client statistics and RADIUS configuration:

```
awplus# show radius statistics
```

Output Figure 69-4: Example output from the **show radius** statistics command:

```
RADIUS statistics for Server: 150.87.18.89
Access-Request Tx : 5 - Retransmit : 0
Access-Accept Rx : 1 - Access-Reject Rx : 2
Access-Challenge Rx : 2
Unknown Type : 0 - Bad Authenticator: 0
Malformed Access-Resp: 0 - Wrong Identifier: 0
Bad Attribute : 0 - Packet Dropped : 0
TimeOut : 0 - Dead count : 0
Pending Request: 0
```

undebug radius

This command applies the functionality of the no debug radius command on page 69.3.

Chapter 70: TACACS+ Introduction and Configuration

Introduction 70.2
TACACS+ Overview 70.2
The AlliedWare Plus TACACS+ Implementation 70.2
Authentication 70.3
Authorization 70.3
Accounting 70.4
Configuration 70.5
Configure TACACS+ 70.5
TACACS+ Configuration Example 70.7

Introduction

This chapter provides information about the AlliedWare Plus implementation of TACACS+ and how to configure it on this switch. For detailed descriptions of the commands used to configure TACACS+, see Chapter 71, TACACS+ Commands. For information about Authentication, Authorization and Accounting (AAA), see Chapter 66, AAA Introduction and Configuration and Chapter 67, AAA Commands.

TACACS+ Overview

TACACS+ (Terminal Access Controller Access-Control System Plus) provides a method for securely managing multiple network access points from a single management service.

TACACS+ is a TCP-based access control protocol, utilizing TCP port 49, that allows a device to forward a user's username and password to an authentication server to determine whether access can be allowed. In addition to this authentication service, TACACS+ can also provide authorization and accounting services.

One of the features of TACACS+ is the ability to separate authentication, authorization and accounting so that these functions can be provided independently on separate servers. Authentication involves identifying a user, typically by requiring the user to supply a valid username and password before access is granted. Following authentication, the user must gain authorization to perform tasks. For example, after logging into a switch, a user may try to issue configuration commands. The authorization process determines whether the user has the authority to issue these commands. Authorization is always preceded by authentication.

The AlliedWare Plus TACACS+ Implementation

The AlliedWare Plus TACACS+ implementation provides authentication, authorization, and accounting. Note that:

- Authorization cannot be performed independently of the authentication process. There are no authorization commands available.
- Authentication and authorization must be configured on the same server.
- Authorization is only applicable if enable password authentication has not been configured with the aaa authentication enable default group tacacs+ command.

With the AlliedWare Plus TACACS+ implementation, all traffic that passes between the TACACS+ client and the TACACS+ servers on the network is encrypted. TACACS+ encrypts the entire payload of packets, which means that it encrypts the user's password between the client and the server.

A TACACS+ client is available on your switch. You need a system running TACACS+ server software from a software provider to use the TACACS+ functionality on your switch.

Authentication

The TACACS+ protocol can forward many types of username and password information. The AlliedWare Plus TACACS+ implementation supports username and password login authentication, as well as enable password authentication. This information is encrypted over the network with MD5 (Message Digest 5).

When TACACS+ login authentication is enabled on the switch with the aaa authentication login command and at least one TACACS+ server is configured and reachable, all user login authentications are authenticated against the TACACS+ server. No local login or other means of authentication is allowed or accepted by the switch unless the switch has been configured to use another authentication method as a backup, and the TACACS+ server is not reachable.

When TACACS+ enable password authentication is enabled on the switch with the aaa authentication enable default group tacacs+ command and at least one TACACS+ server is configured and reachable, all user attempts to access a higher privilege level using the enable (Privileged Exec mode) command are authenticated against the TACACS+ server. If TACACS+ enable password authentication is enabled and the TACACS+ server is not reachable, then the user is only granted access to the desired privilege level if a backup authentication method is also configured.

Note

If TACACS+ login authentication is enabled on the switch, and enable password authentication is configured as default with the aaa authentication enable default local command, then a local enable password must be configured for each privilege level that needs to be accessible to users.

Authorization

In the AlliedWare Plus TACACS+ implementation, authorization cannot be performed independently of the authentication process. Authorization is concerned with what users are allowed to do once they have gained access to the managed device. This involves the passing of Attribute Value pairs (AV pairs) from the TACACS+ server to the managed device. An AV pair is made up of two pieces of information: the attribute that identifies the parameter to be set, and the value that specifies the value to assign to that parameter. These AV pairs are configured on a per-user or per-group basis on the TACACS+ server. The AV pairs that are supported by the AlliedWare Plus TACACS+ implementation are:

- Privilege Level

  Privilege levels range from 1 to 15, with 15 being the highest. For information about privilege levels see "How to Add and Remove Users" on page 1.32 and the username command on page 5.37.

- Timeout

  The value assigned to this attribute specifies the length of time that the session can exist. After this value has expired, the session will either be disconnected, or have the privilege of the user reduced. The valid range of timeout values is 0 to 65535 (minutes).

- Idletime

  If no input or output traffic is received or sent in the period specified by the value for this attribute, the session is disconnected. The valid idletime range is 0 to 65535 (minutes).

Note

In the AlliedWare Plus TACACS+ implementation, authorization for privilege level, timeout, and idletime AV pairs is only attempted if enable password authentication (aaa authentication enable default group tacacs+ command) is not configured. If enable password authentication is configured then the privilege level a user is granted access to is determined during the enable password authentication session.

Accounting

TACACS+ accounting usually takes place after authentication and authorization. However, because TACACS+ separates these three functions, neither authentication nor authorization are required for accounting to function. TACACS+ accounting provides the following two distinct functions:

- a record of services used for billing purposes
- an audit trail for user exec sessions

The AlliedWare Plus TACACS+ accounting implementation supports an audit trail for user exec sessions only. This includes the ability to configure accounting for user logins and logouts, and accounting of any commands executed by the user while they are logged into the switch.

TACACS+ accounting includes three different types of accounting records:

- start records that indicate a service is about to start
- stop records that indicate a service has just ended
- update records that indicate a service is still in progress

Configuration

This section describes how to set up TACACS+ for login authentication, enable password authentication, and accounting.

The TACACS+ server is normally a multiuser system running TACACS+ server software from a software provider. TACACS+ servers are identified on the basis of their host name or IP address. A TACACS+ server and a switch use a shared secret text string to encrypt passwords and exchange responses. To configure TACACS+, you must specify the host running the TACACS+ server software and a secret text string that it shares with the switch.

Configure TACACS+

Table 70-1: General configuration procedure for TACACS+ authentication and accounting

Specify a remote TACACS+ server and the shared secret key	
`awplus#`	
`configure terminal`	Enter Global Configuration mode.
`awplus(config)#`	
`tacacs-server host {<host-name>|<ip-address>} [key [8]<key-string>]`	Specify the IP address or host name of the remote TACACS+ server host and the shared secret key to use with the specified TACACS+ server. Specify 8 if you are entering a password as a string that has already been encrypted instead of entering a plain text password. As many as four TACACS+ servers can be configured and consulted for authentication and accounting. The first server configured is regarded as the primary server and if the primary server fails then the backup servers are consulted in turn.
`awplus(config)#`	
`tacacs-server key [8] <key-string>`	Specify the global shared secret text string used between the switch and all TACACS+ servers. Specify `8` if you are entering a password as a string that has already been encrypted instead of entering a plain text password. If no secret key is explicitly specified for a TACACS+ server with the tacacs-server host command, the global secret key will be used.
Specify the timeout value	
`awplus(config)#`	
`tacacs-server timeout <seconds>`	Specify for how many seconds a switch waits for a reply to a TACACS+ request before considering the TACACS+ server dead.
Define the method list for TACACS+ login authentication	
`awplus(config)#`	
`aaa authentication login {default|<list-name>} {[local] [group {radius|tacacs+|<group-name>}]}`	This method list defines the AAA server type used for login authentication. The server types are always used in the order specified with this command. If the first server in the method list is unreachable, the switch sends the request to the next server in the list. If the authentication server denies the authentication request because of an incorrect username or password then the user login fails.

Table 70-1: General configuration procedure for TACACS+ authentication and accounting(cont.)

Define the method list for TACACS+ enable password authentication	
`awplus(config)#`	
`aaa authentication enable default group tacacs+ [local] [none]`	This method list defines the authentication method used to determine the privilege command level a user can access. Specify local to use the locally configured enable password and none to grant access to Privileged Exec mode with no authentication, if the TACACS+ server goes offline, or is not reachable during enable password authentication.
Define the method for TACACS+ login accounting	
`awplus(config)#`	
`aaa accounting login {default|<list-name>} {start-stop|stop-only|none} {group {radius|tacacs+|<group-name>}}`	You can only define one method for login accounting, either RADIUS or TACACS+. Specify start-stop to send both start and stop login accounting records, stop-only to send only stop login accounting records, or none to disable the sending of login accounting records.
Configure TACACS+ command accounting	
`awplus(config)#`	
`aaa accounting commands <1-15> default stop-only group tacacs+`	TACACS+ command accounting is configured per privilege level and only commands of the specified privilege level are accounted. Therefore, if you require that all commands are accounted to the TACACS+ server, you must configure command accounting for each privilege level separately. Commands are accounted to the TACACS+ server after they have successfully executed.
Troubleshooting TACACS+	
`awplus(config)#`	
`show tacacs+`	Display the current TACACS+ server configuration and status.
`awplus#`	
`debug aaa authentication`	Enable debug output for TACACS+ authentication.
`awplus#`	
`debug aaa authorization`	Enable debug output for TACACS+ authorization.
`awplus#`	
`debug aaa accounting`	Enable debug output for TACACS+ accounting.

TACACS+ Configuration Example

Example The following example shows how to configure the switch to authenticate and account using TACACS+.

Figure 70-1: Sample TACACS+ authentication and accounting to configure the switch to authenticate and account user exec sessions

```
!
tacacs-server host 172.10.10.1
tacacs-server key tacacspass
aaa authentication login admin group tacacs+ local
aaa authentication enable default group tacacs+ local
aaa accounting login admin start-stop group tacacs+
aaa accounting commands 1 default stop-only group tacacs+
aaa accounting commands 7 default stop-only group tacacs+
aaa accounting commands 15 default stop-only group tacacs+

line console 0
login authentication admin
accounting login admin
!
```

The lines in this example TACACS+ authentication and accounting configuration are defined as follows:

- The tacacs-server host command defines the IP address of the TACACS+ server host.
- The tacacs-server key command defines the global shared secret text string between the network access server and the TACACS+ server host.
- The aaa authentication login command defines a method list named admin to use first the TACACS+ servers and then the local user database for user login authentication.
- The aaa authentication enable default group tacacs+ command defines a method list to use first the TACACS+ servers and then the local enable passwords, set with the enable password command, for user enable password authentication.
- The aaa accounting login command defines a method named admin to use TACACS+ servers for login accounting.
- The aaa accounting commands command specifies the privilege level of the commands that will be accounted.
- The login authentication command specifies that this method list will be used for authenticating users logging in on the asynchronous console port.
- The accounting login command specifies that this method list will be used for accounting users logging in on the asynchronous console port.

Chapter 71: TACACS+ Commands

Command List 71.2
tacacs-server host 71.2
tacacs-server key 71.4
tacacs-server timeout 71.5
show tacacs+ 71.6

Command List

This chapter provides an alphabetical reference for commands used to configure the device to use TACACS+ servers. For more information about TACAC+, see Chapter 70, TACACS+ Introduction and Configuration.

tacacs-server host

Use this command to specify a remote TACACS+ server host for authentication, authorization and accounting, and to set the shared secret key to use with the TACACS+ server. The parameters specified with this command override the corresponding global parameters for TACACS+ servers.

Use the no variant of this command to remove the specified server host as a TACACS+ authentication and authorization server.

Syntax

```
tacacs-server host {<host-name>|<ip-address>} [key [8]<key-string>]
no tacacs-server host {<host-name>|<ip-address>}
```

Parameter	Description
<host-name>	Server host name. The DNS name of the TACACS+ server host.
<ip-address>	The IP address of the TACACS+ server host, in dotted decimal notation A.B.C.D.
key	Set shared secret key with TACACS+ servers.
8	Specifies that you are entering a password as a string that has already been encrypted instead of entering a plain text password. The running config displays the new password as an encrypted string even if password encryption is turned off.
<key-string>	Shared key string applied, a value in the range 1 to 64 characters. Specifies the shared secret authentication or encryption key for all TACACS+ communications between this device and the TACACS+ server. This key must match the encryption used on the TACACS+ server. This setting overrides the global setting of the tacacs-server key command. If no key value is specified, the global value is used.

Default No TACACS+ server is configured by default.

Mode Global Configuration

Usage A TACACS+ server host cannot be configured multiple times like a RADIUS server.

As many as four TACACS+ servers can be configured and consulted for login authentication, enable password authentication and accounting. The first server configured is regarded as the primary server and if the primary server fails then the backup servers are consulted in turn. A backup server is consulted if the primary server fails, not if a login authentication attempt is rejected. The reasons a server would fail are:

- it is not network reachable
- it is not currently TACACS+ capable
- it cannot communicate with the switch properly due to the switch and the server having different secret keys

Examples To add the server `tac1.company.com` as the TACACS+ server host, use the following commands:

```
awplus# configure terminal
awplus(config)# tacacs-server host tac1.company.com
```

To set the secret key to `secret` on the TACACS+ server `192.168.1.1`, use the following commands:

```
awplus# configure terminal
awplus(config)# tacacs-server host 192.168.1.1 key secret
```

To remove the TACACS+ server `tac1.company.com`, use the following commands:

```
awplus# configure terminal
awplus(config)# no tacacs-server host tac1.company.com
```

Related Commands
aaa accounting commands
aaa authentication login
tacacs-server key
tacacs-server timeout
show tacacs+

tacacs-server key

This command sets a global secret key for TACACS+ authentication, authorization and accounting. The shared secret text string is used for TACACS+ communications between the switch and all TACACS+ servers.

Note that if no secret key is explicitly specified for a TACACS+ server with the tacacs-server host command, the global secret key will be used for the shared secret for the server.

Use the no variant of this command to remove the global secret key.

Syntax

```
tacacs-server key [8] <key-string>
no tacacs-server key
```

Parameter	Description
8	Specifies a string in an encrypted format instead of plain text. The running config will display the new password as an encrypted string even if password encryption is turned off.
<key-string>	Shared key string applied, a value in the range 1 to 64 characters. Specifies the shared secret authentication or encryption key for all TACACS+ communications between this device and all TACACS+ servers. This key must match the encryption used on the TACACS+ server.

Mode Global Configuration

Usage Use this command to set the global secret key shared between this client and its TACACS+ servers. If no secret key is specified for a particular TACACS+ server using the tacacs-server host command, this global key is used.

Examples To set the global secret key to `secret` for TACACS+ server, use the following commands:

```
awplus# configure terminal
awplus(config)# tacacs-server key secret
```

To delete the global secret key for TACACS+ server, use the following commands:

```
awplus# configure terminal
awplus(config)# no tacacs-server key
```

Related Commands tacacs-server host
show tacacs+

tacacs-server timeout

Use this command to specify the TACACS+ global timeout value. The timeout value is how long the device waits for a reply to a TACACS+ request before considering the server to be dead.

Note that this command configures the timeout parameter for TACACS+ servers globally.

The no variant of this command resets the transmit timeout to the default (5 seconds).

Syntax

```
tacacs-server timeout <seconds>
no tacacs-server timeout
```

Parameter	Description
<seconds>	TACACS+ server timeout in seconds, in the range 1 to 1000.

Default The default timeout value is 5 seconds.

Mode Global Configuration

Examples To set the timeout value to 3 seconds, use the following commands:

```
awplus# configure terminal
awplus(config)# tacacs-server timeout 3
```

To reset the timeout period for TACACS+ servers to the default, use the following commands:

```
awplus# configure terminal
awplus(config)# no tacacs-server timeout
```

Related Commands

tacacs-server host
show tacacs+

show tacacs+

This command displays the current TACACS+ server configuration and status.

Syntax `show tacacs+`

Mode User Exec and Privileged Exec

Example To display the current status of TACACS+ servers, use the command:

```
awplus# show tacacs+
```

Output Figure 71-1: Example output from the **show tacacs+** command

```
TACACS+ Global Configuration
  Timeout              : 5 sec

Server Host/       Server
IP Address         Status
------------------------------------------------------------
192.168.1.10       Alive
192.168.1.11       Unknown
```

Table 71-1: Parameters in the output of the **show tacacs+** command

Output Parameter	Meaning	
`Timeout`	A time interval in seconds.	
`Server Host/IP Address`	TACACS+ server hostname or IP address.	
`Server Status`	The status of the authentication port.	
	`Alive`	The server is alive.
	`Dead`	The server has timed out.
	`Error`	The server is not responding or there is an error in the key string entered.
	`Unknown`	The server is never used or the status is unkown.
	`Unreachable`	The server is unreachable.
	`Unresolved`	The server name can not be resolved.

Chapter 72: Local RADIUS Server Introduction and Configuration

Local RADIUS Server Introduction 72.2
- Enable the Local RADIUS Server 72.2
- Add the Local RADIUS Server as a RADIUS Server 72.3
- Add authenticators to the list of authenticators 72.3
- Configure the Local RADIUS Server User Database 72.4
- Authenticating login sessions 72.5
- RADIUS Authentication with User Privileges 72.5
- Creating certificates for single users and all users 72.7

Defined RADIUS attributes list 72.8

Local RADIUS Server Introduction

Local RADIUS Server provides a user authentication service feature. This feature must be enabled on the switch, because it is disabled by default. For details of commands used to configure the local RADIUS server, see Chapter 73, Local RADIUS Server Commands.

Enable the Local RADIUS Server

The Local RADIUS Server is disabled by default. Enter the following commands to enable the Local RADIUS Server:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# server enable
```

This will automatically initialize the internal Certificate Authority (CA) in the switch. It will also automatically create a server certificate and enrol the certificate with the Local CA by implicitly executing the following commands:

```
awplus(config)# crypto pki trustpoint local
awplus(config)# crypto pki enroll local
```

The crypto pki trustpoint local command declares the Local CA as the CA from which to obtain Certificates. The Local CA has be defined first so Certificates can be obtained from it. The crypto pki enroll local command obtains the system certificate from the Local CA.

The switch is automatically added to the list of authenticators that may send authentication requests to the Local RADIUS Server by implicitly executing the following commands:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# nas 127.0.0.1 key awplus-local-radius-
server
```

Note

The key awplus-local-radius-server is a pre-defined component that can be used for internal exchanges between the switch's RADIUS client and its RADIUS server.

Add the Local RADIUS Server as a RADIUS Server

Although the switch is automatically defined as a NAS (Network Access Server) for the Local RADIUS Server, you must manually add the Local RADIUS Server to the server list defined for the Local RADIUS Client.

Use the following commands to add the Local RADIUS Server as a RADIUS Server. The Local RADIUS Client can then send authentication requests to its Local RADIUS Server:

```
awplus# configure terminal
awplus(config)# radius-server host 127.0.0.1 key awplus-local-
radius-server
```

Add authenticators to the list of authenticators

Authenticators can send authentication requests to the Local RADIUS Server.

Use the following commands to add other authenticators to the list of authenticators.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# nas <nas-ip-address> key <nas-keystring>
```

Configure the Local RADIUS Server User Database

Add users to the RADIUS user list without assigning VLANs

For entries that will be used to authenticate dot1x supplicants, but not assign them to a VLAN, the following commands will add users to the RADIUS user list:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# user <radius-user-name> password <user-password>
```

Add users to the RADIUS user list and assign VLANs

Add users to the RADIUS user list, and define a VLAN ID that will be assigned to them.

To add entries to be used to authenticate dot1x supplicants, and assign them to a VLAN, follow the two steps shown below:

Step 1: Create groups associated with the VIDs that will be allocated

Enter the following commands to create groups with the VIDs that will be allocated to them:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# group VLAN10Users
awplus(config-radsrv)# vlan 10
awplus(config-radsrv)# group VLAN11Users
awplus(config-radsrv)# vlan 11
```

Step 2: Add the users after creating groups

Add the users and refer to the relevant group in the command that creates the user as below:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# user VCSPCVLAN10 password VCSPCPass
                       group VLAN10Users
awplus(config-radsrv)# user VCSPCVLAN11 password VCSPCPass
                       group VLAN11Users
```

Authenticating login sessions

Authentication can be performed in multiple contexts, such as the authentication of users logging in at a console, as well as tri-authentication of devices connecting to switch ports, see Tri-Authentication Configuration in Chapter 64, Authentication Introduction and Configuration.

RADIUS Authentication with User Privileges

A new security privilege level is available from release 5.4.1. Users with privilege levels 1 to 6 will continue to have access to privilege 1 level commands. Users with privilege 7 to 14 will have access to level 1 commands plus all show commands. Users with privilege level 15 will continue to have access to all commands.

As a result of this new intermediate access level, when a user logs into a management session on a switch running release 5.4.1, and is being authenticated by RADIUS, the RADIUS server needs to be able to indicate to the switch what privilege level to assign to the user's session.

In particular, this means that extra configuration is now required when the RADIUS Server is being set up with users for who will be logging into the switch by console, telnet, or SSH.

The way that the privilege level is associated with a user is, of course, to use the RADIUS attributes. The attributes are configured on RADIUS groups.

Since there are now three security privilege levels there will need to be up to three different groups for login users; each group specifying a different privilege level.

The attributes that need to be configured on the three different RADIUS groups are as follows:

1. For the users with a privilege level of 1-6 use just the RADIUS `attribute Service-Type`, and assign it the value `NAS-Prompt-User`:

```
attribute Service-Type NAS-Prompt-User
```

2. For users with the security privilege of 7-14 use the following 2 RADIUS attributes:

```
attribute Cisco-AVPair shell:priv-lvl=7
attribute Service-Type NAS-Prompt-User
```

3. User with the administrator security privilege use just the RADIUS `attribute Service-Type`, and assign it the value `Administrative-User`:

```
attribute Service-Type Administrative-User
```

Since there is not an explicit RADIUS attribute for the users with the security privilege level 7, we use "`Cisco-AVPair`" to specify this user privilege. But it's very important that we also specify the attribute `Service-Type NAS-Prompt-User` as well, otherwise the following error is generated when a user allocated to this group tries to login into the AlliedWare Plus switch:

```
19:09:14 awplus login[16974]: Invalid user name "tests" in main:698.
Abort.
```

The RADIUS Server attribute `NAS-Prompt-User` is used for non-privileged level users as per the RADIUS RFC. This attribute is used for users with security privilege levels of 1 to 6.

Configuring these RADIUS Server attributes is achieved using Local RADIUS Server commands:

```
                    awplus# configure terminal
             awplus(config)# radius-server local
       awplus(config-radsrv)# group users
awplus(config-radsrv-group)# attribute Service-Type NAS-
                              Prompt_User
```

See the below sample configuration for an AlliedWare Plus switch acting as the RADIUS Server, with the three different security privileges for `admin`, `middle-management`, and `users` groups:

Figure 72-1: Sample RADIUS Server configuration for three different security privileges:

```
crypto pki trustpoint local
!
crypto pki enroll local
radius-server local
 server enable
 nas 10.1.1.1 key test
 nas 127.0.0.1 key awplus-local-radius-server
 group admin
  attribute Service-Type Administrative-User
 group middle-management
  attribute Cisco-AVPair shell:priv-lvl=7
  attribute Service-Type NAS-Prompt-User
 group users
  attribute Service-Type NAS-Prompt-User
 user test encrypted password UukoSyvxY2v9iWXm8e/
JMDJd9iIc3RPyY09lGOb3pA4= group  users
 user tested encrypted password
sEDhM4iJRfJrLhhs+RgjpgkDXtCwuji6AllpApi9EjA= group admin
 user tests encrypted password il9aIh8JLOT6kHDV+Ix7/
8fzyfVpAwRErJg6NPQdJy8= group middle-management
```

Removing users from the RADIUS users list

To remove the user Tom from the user database of the Local RADIUS server, use the commands:

```
                    awplus# configure terminal
             awplus(config)# radius-server local
awplus(config-radsrv)# no user Tom
```

Creating certificates for single users and all users

Create a certificate for a single user

A certificate for user Tom can be created from the local CA by using the commands:

```
awplus# configure terminal
awplus(config)# crypto pki enroll local user Tom
```

Create a certificate for all users

Certificates can be created for all currently defined users by using the commands:

```
awplus# configure terminal
awplus(config)# crypto pki enroll local local-radius-all-users
```

Exporting certificates

User certificates can be exported in PKCS12 format.

To export a certificate for user Tom and upload it to the TFTP server at 192.168.1.1, use the commands:

```
awplus# configure terminal
awplus(config)# crypto pki export local pkcs12 Tom tftp://
192.168.1.1/tomcert.pkcs
```

Defined RADIUS attributes list

This is a full list of valid attributes and pre-defined values that may be used in conjunction with the attribute command on page 73.2, to show or configure defined RADIUS attributes.

Table 72-1 lists all Standard attributes and values, Table 72-2 lists the Vendor-Specific attribute (attribute ID 26) names and values.

More detailed information can be found in the following RFCs, defining the attributes and values for RADIUS server:

- RFC2865: Remote Authentication Dial In User Service (RADIUS)
- RFC2866: RADIUS Accounting
- RFC2867: RADIUS Accounting Modifications for Tunnel Protocol Support
- RFC2868: RADIUS Attributes for Tunnel Protocol Support
- RFC2869: RADIUS Extensions
- RFC3162: RADIUS and IPv6
- RFC3576: Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)
- RFC3580: IEEE 802.1X Remote Authentication Dial In User Service (RADIUS) Usage Guidelines
- RFC4072: Diameter Extensible Authentication Protocol (EAP) Application
- RFC4372: Chargeable User Identity
- RFC4603: Additional Values for the NAS-Port-Type Attribute
- RFC4675: RADIUS Attributes for Virtual LAN and Priority Support
- RFC4679: DSL Forum Vendor-Specific RADIUS Attributes
- RFC4818: RADIUS Delegated-IPv6-Prefix Attribute
- RFC4849: RADIUS Filter Rule Attribute
- RFC5176: Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)
- RFC5580: Carrying Location Objects in RADIUS and Diameter
- RFC5607: Remote Authentication Dial-In User Service (RADIUS) Authorization for Network Access Server (NAS) Management
- RFC5904: RADIUS Attributes for IEEE 802.16 Privacy Key Management Version 1 (PKMv1) Protocol Support

Table 72-1: Standard RADIUS Attributes

Attribute ID and Name		Value Type/Pre-defined Values
1	User-Name	string
2	User-Password	string
3	CHAP-Password	octets (Hexadecimal string followed by 0x)
4	NAS-IP-Address	ipaddr (IPv4 address)
5	NAS-Port	Integer
6	Service-Type	Integer. Valid values are: ■ Administrative-User (6) ■ Authenticate-Only (8) ■ Authorize-Only (17) ■ Callback-Administrative (11) ■ Callback-Framed-User (4) ■ Callback-Login-User (3) ■ Callback-NAS-Prompt (9) ■ Call-Check (10) ■ Framed-Management (18) ■ Framed-User (2) ■ Login-User (1) ■ NAS-Prompt-User (7) ■ Outbound-User (5)
7	Framed-Protocol	Integer. Valid values are: ■ ARAP (3) ■ Gandalf-SLML (4) ■ PPP (1) ■ SLIP (2) ■ X.75-Synchronous (6) ■ Xylogics-IPX-SLIP (5)
8	Framed-IP-Address	ipaddr (IPv4 address)
9	Framed-IP-Netmask	ipaddr (IPv4 address)
10	Framed-Routing	integer. Valid values are: ■ Broadcast (1) ■ Broadcast-Listen (3) ■ Listen (2) ■ None (0)
11	Filter-Id	string
12	Framed-MTU	Integer
13	Framed-Compression	Integer. Valid values are: ■ IPX-Header-Compression (2) ■ None (0) ■ Stac-LZS (3) ■ Van-Jacobson-TCP-IP (1)
14	Login-IP-Host	IP Address

Table 72-1: Standard RADIUS Attributes(cont.)

Attribute ID and Name		Value Type/Pre-defined Values
15	Login-Service	Integer. Valid values are: ■ LAT (4) ■ PortMaster (3) ■ Rlogin (1) ■ TCP-Clear (2) ■ TCP-Clear-Quiet (8) ■ Telnet (0) ■ X25-PAD (5) ■ X25-T3POS (6)
16	Login-TCP-Port	Integer. Valid values are: ■ Rlogin (513) ■ Rsh (514) ■ Telnet (23)
18	Reply-Message	string
19	Callback-Number	string
20	Callback-Id	string
22	Framed-Route	string
23	Framed-IPX-Network	IP address
24	State	octets (Hexadecimal string followed by 0x)
25	Class	octets (Hexadecimal string followed by 0x)
26	Vendor-Specific	Use the Vendor-specific Attribute Name. For valid values, see "Vendor-Specific RADIUS Attributes" on page 72.17.
27	Session-Timeout	Integer
28	Idle-Timeout	Integer
29	Termination-Action	Integer. Valid values are: ■ Default (0) ■ RADIUS-Request (1)
30	Called-Station-Id	string
31	Calling-Station-Id	string
32	NAS-Identifier	string
33	Proxy-State	octets (Hexadecimal string followed by 0x)
34	Login-LAT-Service	string
35	Login-LAT-Node	string
36	Login-LAT-Group	octets (Hexadecimal string followed by 0x)
37	Framed-AppleTalk-Link	Integer
38	Framed-AppleTalk-Network	Integer

Table 72-1: Standard RADIUS Attributes(cont.)

Attribute ID and Name		Value Type/Pre-defined Values
39	Framed-AppleTalk-Zone	string
40	Acct-Status-Type	Integer. Valid values are: ■ Accounting-Off (8) ■ Accounting-On (7) ■ Alive (3) ■ Failed (15) ■ Interim-Update (3) ■ Start (1) ■ Stop (2) ■ Tunnel-Link-Reject (14) ■ Tunnel-Link-Start (12) ■ Tunnel-Link-Stop (13) ■ Tunnel-Reject (11) ■ Tunnel-Start (9) ■ Tunnel-Stop (10)
41	Acct-Delay-Time	Integer
42	Acct-Input-Octets	Integer
43	Acct-Output-Octets	Integer
44	Acct-Session-Id	string
45	Acct-Authentic	Integer. Valid values are: ■ Diameter (4) ■ Local (2) ■ RADIUS (1) ■ Remote (3)
46	Acct-Session-Time	Integer
47	Acct-Input-Packets	Integer
48	Acct-Output-Packets	Integer

Table 72-1: Standard RADIUS Attributes(cont.)

Attribute ID and Name		Value Type/Pre-defined Values
49	Acct-Terminate-Cause	Integer. Valid values are: ■ Admin-Reboot (7) ■ Admin-Reset (6) ■ Callback (16) ■ Host-Request (18) ■ Idle-Timeout (4) ■ Lost-Carrier (2) ■ Lost-Service (3) ■ NAS-Error (9) ■ NAS-Reboot (11) ■ NAS-Request (10) ■ Port-Disabled (22) ■ Port-Error (8) ■ Port-Preempted (13) ■ Port-Reinit (21) ■ Port-Suspended (14) ■ Port-Unneeded (12) ■ Reauthentication-Failure (20) ■ Service-Unavailable (15) ■ Session-Timeout (5) ■ Supplicant-Restart (19) ■ User-Error (17) ■ User-Request (1)
50	Acct-Multi-Session-Id	string
51	Acct-Link-Count	Integer
52	Acct-Input-Gigawords	Integer
53	Acct-Output-Gigawords	Integer
55	Event-Timestamp	date (Not supported)
56	Egress-VLANID	Integer
57	Ingress-Filters	Integer. Valid values are: ■ Disabled (2) ■ Enabled (1)
58	Egress-VLAN-Name	string
59	User-Priority-Table	octets (Hexadecimal string followed by 0x)
60	CHAP-Challenge	octets (Hexadecimal string followed by 0x)
61	NAS-Port-Type	Integer. Valid values are: ■ ADSL-CAP (12) ■ ADSL-DMT (13) ■ Async (0) ■ Cable (17) ■ Ethernet (15) ■ FDDI (21) ■ G.3-Fax (10) ■ HDLC-Clear-Channel (7)

Table 72-1: Standard RADIUS Attributes(cont.)

Attribute ID and Name		Value Type/Pre-defined Values
61	NAS-Port-Type (cont.)	Integer. Valid values are: ■ IDSL (14) ■ ISDN (2) ■ ISDN-V110 (4) ■ ISDN-V120 (3) ■ PIAFS (6) ■ PPPoA (30) ■ PPPoEoA (31) ■ PPPoEoE (32) ■ PPPoEoQinQ (34) ■ PPPoEoVLAN (33) ■ SDSL (11) ■ Sync (1) ■ Token-Ring (20) ■ Virtual (5) ■ Wireless-802.11 (19) ■ Wireless-Other (18) ■ X.25 (8) ■ X.75 (9) ■ xDSL (16)
62	Port-Limit	Integer
63	Login-LAT-Port	string
64	Tunnel-Type	Integer. Valid values are: ■ AH (6) ■ ATMP (4) ■ DVS (11) ■ ESP (9) ■ GRE (10) ■ IP (7) ■ IP-in-IP (12) ■ L2F (2) ■ L2TP (3) ■ MIN-IP (8) ■ PPTP (1) ■ VLAN (13) ■ VTP (5)

Table 72-1: Standard RADIUS Attributes(cont.)

Attribute ID and Name		Value Type/Pre-defined Values
65	Tunnel-Medium-Type	Integer. Valid values are: ■ Appletalk (12) ■ Banyan-Vines (14) ■ BBN-1822 (5) ■ DecNet-IV (13) ■ E.163 (7) ■ E.164 (8) ■ E.164-NSAP (15) ■ F.69 (9) ■ HDLC (4) ■ IEEE-802 (6) ■ IP (1) ■ IPv4 (1) ■ IPv6 (2) ■ IPX (11) ■ NSAP (3) ■ X.121 (10)
66	Tunnel-Client-Endpoint	string
67	Tunnel-Server-Endpoint	string
68	Acct-Tunnel-Connection	string
69	Tunnel-Password	string
70	ARAP-Password	octets (Hexadecimal string followed by 0x)
71	ARAP-Features	octets (Hexadecimal string followed by 0x)
72	ARAP-Zone-Access	Integer. Valid values are: ■ Default-Zone (1) ■ Zone-Filter-Exclusive (4) ■ Zone-Filter-Inclusive (2)
73	ARAP-Security	Integer
74	ARAP-Security-Data	string
75	Password-Retry	integer
76	Prompt	integer. Valid values are: ■ Echo (1) ■ No-Echo (0)
77	Connect-Info	string
78	Configuration-Token	string
79	EAP-Message	octets (Hexadecimal string followed by 0x)
80	Message-Authenticator	octets (Hexadecimal string followed by 0x)
81	Tunnel-Private-Group-Id	string
82	Tunnel-Assignment-Id	string
83	Tunnel-Preference	Integer

Table 72-1: Standard RADIUS Attributes(cont.)

Attribute ID and Name		Value Type/Pre-defined Values
84	ARAP-Challenge-Response	octets (Hexadecimal string followed by 0x)
85	Acct-Interim-Interval	Integer
86	Acct-Tunnel-Packets-Lost	Integer
87	NAS-Port-Id	string
88	Framed-Pool	string
89	Chargeable-User-Identity	string
90	Tunnel-Client-Auth-Id	string
91	Tunnel-Server-Auth-Id	string
92	NAS-Filter-Rule	string
95	NAS-IPv6-Address	ipv6addr (IPv6 address)
96	Framed-Interface-Id	ifid (Not supported)
97	Framed-IPv6-Prefix	ipv6prefix (Not supported)
98	Login-IPv6-Host	ipv6addr (IPv6 address)
99	Framed-IPv6-Route	string
100	Framed-IPv6-Pool	string
101	Error-Cause	Integer. Valid values are: ■ Administratively-Prohibited (501) ■ Invalid-Attribute-Value (407) ■ Invalid-EAP-Packet (202) ■ Invalid-Request (404) ■ Missing-Attribute (402) ■ Multiple-Session-Selection-Unsupported (508) ■ NAS-Identification-Mismatch (403) ■ Proxy-Processing-Error (505) ■ Proxy-Request-Not-Routable (502) ■ Request-Initiated (507) ■ Residual-Context-Removed (201) ■ Resources-Unavailable (506) ■ Session-Context-Not-Found (503) ■ Session-Context-Not-Removable (504) ■ Unsupported-Attribute (401) ■ Unsupported-Extension (406) ■ Unsupported-Service (405)
102	EAP-Key-Name	string
123	Delegated-IPv6-Prefix	ipv6prefix
126	Operator-Name	string

user (RADIUS server) 73.36
vlan (RADIUS server) 73.38

Command List

This chapter provides an alphabetical reference for commands used to configure the local RADIUS server on the device. For more information, see Chapter 72, Local RADIUS Server Introduction and Configuration.

attribute

Use this command to define a RADIUS attribute for the local RADIUS server user group.

For a complete list of defined RADIUS attributes and values, see "Defined RADIUS attributes list" on page 72.8.

When used with the help parameter the attribute command displays a list of standard and vendor specific valid RADIUS attributes that are supported by the local RADIUS server.

If an attribute name is specified with the help parameter, then the attribute command displays a list of predefined attribute names. Note that you can only use the defined RADIUS attribute names and not define your own.

When used with the value parameter the attribute command configures RADIUS attributes to the user group. If the specified attribute is already defined then it is replaced with the new value.

Use the no variant of this command to delete an attribute from the local RADIUS server user group.

Syntax

```
attribute [<attribute-name>|<attribute-id>] help
attribute {<attribute-name>|<attribute-id>} <value>
no attribute {<attribute-name>|<attribute-id>}
```

Parameter	Description
<attribute-name>	RADIUS attribute name for standard attributes (see Table 72-1 on page 72.9) or Vendor-Specific attributes (see Table 72-2 on page 72.17).
<attribute-id>	RADIUS attribute numeric identifier for standard attributes (Table 72-1 on page 72.9).
<value>	RADIUS attribute value.
help	Display a list of available attribute types.

Default By default, no attributes are configured.

Mode RADIUS Server Group Configuration

Usage For the Standard attributes, the attribute may be specified using either the attribute name, or its numeric identifier. For example, command:

```
awplus(config-radsrv-group)# attribute acct-terminate-cause
                             help
```

will produce the same results as command:

```
awplus(config-radsrv-group)# attribute 49 help
```

In the same way, where the specific attribute has a pre-defined value, the parameter <*value*> may be substituted with the Value Name or with its numeric value, for example command:

```
awplus(config-radsrv-group)# attribute acct-terminate-cause
                             user-request
```

will produce the same results as command:

```
awplus(config-radsrv-group)# attribute 49 1
```

or command:

```
awplus(config-radsrv-group)# attribute acct-terminate-cause 1
```

Example To check a list of all available defined RADIUS attribute names, use the following commands:

```
                    awplus# configure terminal
                awplus(config)# radius-server local
          awplus(config-radsrv)# group Admin
awplus(config-radsrv-group)# attribute help
```

A list of Vendor-specific Attributes displays after the list of defined Standard Attributes.

To get help for valid RADIUS attribute values for the attribute `Service-Type`, use the following commands:

```
                    awplus# configure terminal
                awplus(config)# radius-server local
          awplus(config-radsrv)# group Admin
awplus(config-radsrv-group)# attribute Service-Type help
```

```
Service-Type : integer (Integer number)
Pre-defined values :
    Administrative-User (6)
    Authenticate-Only (8)
    Authorize-Only (17)
    Callback-Administrative (11)
    Callback-Framed-User (4)
    Callback-Login-User (3)
    Callback-NAS-Prompt (9)
    Call-Check (10)
    Framed-User (2)
    Login-User (1)
    NAS-Prompt-User (7)
    Outbound-User (5)
```

To define the attribute name 'Service-Type' with Administrative User (6) to the RADIUS User Group 'Admin', use the following commands:

```
                    awplus# configure terminal
                awplus(config)# radius-server local
          awplus(config-radsrv)# group Admin
    awplus(config-radsrv-group)# attribute Service-Type 6
```

To delete the attribute 'Service-Type' from the RADIUS User Group 'Admin', use the following commands:

```
                    awplus# configure terminal
                awplus(config)# radius-server local
          awplus(config-radsrv)# group Admin
    awplus(config-radsrv-group)# no attribute Service-Type
```

Related Commands egress-vlan-id
egress-vlan-name

authentication

Use this command to enable the specified authentication methods on the local RADIUS server.

Use the no variant of this command to disable specified authentication methods on the local RADIUS server.

Syntax

```
authentication {mac|eapmd5|eaptls|peap}
no authentication {mac|eapmd5|eaptls|peap}
```

Parameter	Description
mac	Enable MAC authentication method.
eapmd5	Enable EAP-MD5 authentication method.
eaptls	Enable EAP-TLS authentication method.
peap	Enable EAP-PEAP authentication method.

Default All authentication methods are enabled by default.

Mode RADIUS Server Configuration

Example The following commands enable EAP-MD5 authentication methods on the local RADIUS server.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# authentication eapmd5
```

The following commands disable EAP-MD5 authentication methods on Local RADIUS server.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# no authentication eapmd5
```

Related Commands

server enable
show radius local-server statistics

clear radius local-server statistics

Use this command to clear the statistics stored on the switch for the local RADIUS server.

Use this command without any parameters to clear all types of local RADIUS server statistics.

Syntax `clear radius local-server statistics [nas|server|user]`

Parameter	Description
`nas`	Clear the NAS (Network Access Server) statistics on the switch. For example, clearing statistics stored for NAS server invalid passwords.
`server`	Clear the Local RADIUS Server statistics on the switch. For example, clearing Local RADIUS Servers statistics for all failed login attempts.
`user`	Clear the Local RADIUS Server user statistics. For example, clearing statistics stored for the number of successful user logins.

Mode Privileged Exec

Usage Refer to the sample output for the show radius local-server statistics for further information about the type of statistics each parameter option for this command clears. Both the nas and server parameters clear unknown username and invalid passwords statistics, while the `user` parameter clears the number of successful and failed logins for each local RADIUS server user.

Example To clear the NAS (Network Access Server) statistics stored on the switch, use the command:.

```
awplus# clear radius local-server statistics nas
```

To clear the local RADIUS server statistics stored on the switch, use the command:.

```
awplus# clear radius local-server statistics server
```

To clear the local RADIUS server user statistics stored on the switch, use the command:.

```
awplus# clear radius local-server statistics user
```

Related Commands show radius local-server statistics

copy fdb-radius-users (to file)

Use this command to create a set of local RADIUS server users from MAC addresses in the local FDB. A local RADIUS server user created using this command can be used for MAC authentication.

Syntax

```
copy fdb-radius-users {local-radius-user-db|flash|nvs|card|debug|
   tftp|scp|<url>} [interface <port>] [vlan <vid>] [group <name>]
   [export-vlan [<group-name>]]
```

Parameter	Description
`local-radius-user-db`	Copy the local RADIUS server users created to the local RADIUS server.
`flash`	Copy the local RADIUS server users created to Flash memory.
`nvs`	Copy the local RADIUS server users created to NVS memory.
`card`	Copy the local RADIUS server users created to SD card.
`debug`	Copy the local RADIUS server users created to debug.
`tftp`	Copy the local RADIUS server users created to the TFTP destination.
`scp`	Copy the local RADIUS server users created to the SCP destination.
`<url>`	Copy the local RADIUS server users created to the specified URL.
`interface <port>`	Copy only MAC addresses learned on a specified switch port. Wildcards may be used when specifying an interface name. For example, when you specify interface port1.* then this command generates RADIUS server users for MAC addresses learned on stack 1.
`vlan <vid>`	Copy only MAC addresses learned on a specified VLAN.
`group <name>`	Assign a RADIUS group name to the local RADIUS server users created.
`export-vlan <group-name>`	Assign a RADIUS group name to the assigned export VLAN.

Mode Privileged Exec

Usage The local RADIUS server users created are written to a specified destination file in local RADIUS user CSV (Comma Separated Values) format. The local RADIUS server users can then be imported to a local RADIUS server using the copy local-radius-user-db (from file) command.

The name and password of the local RADIUS server users created use a MAC address, which can be used for MAC authentication.

This command does not copy a MAC address learned by the CPU or the management port.

This command can filter FDB entries by the interface name and the VLAN ID. When the interface name and the VLAN ID are specified, this command generates local RADIUS server users from only the MAC address learned on the specified interface and on the specified VLAN.

Examples To register the local RADIUS server users from the local FDB directly to the local RADIUS server, use the command:

```
awplus# copy fdb-radius-users local-radius-user-db
```

To register the local RADIUS server users from the interface `port1.0.1` to the local RADIUS server, use the command:

```
awplus# copy fdb-radius-users local-radius-user-db interface
       port1.0.1
```

To copy output generated as local RADIUS server user data from MAC addresses learned on `vlan10` on interface `port1.0.1` to the file `radius-user.csv`, use the command:

```
awplus# copy fdb-radius-users radius-user.csv interface
       port1.0.1 vlan10
```

Related Commands copy local-radius-user-db (to file)
copy local-radius-user-db (from file)

copy local-radius-user-db (from file)

Use this command to copy the Local RADIUS server user data from a file. The file, including the RADIUS user data in the file, must be in the CSV (Comma Separated Values) format.

You can select add or replace as the copy method. The add parameter option copies the contents of specified file to the local RADIUS server user database. If the same user exists then the old user is removed before adding a new user. The replace parameter option deletes all contents of the local RADIUS server user database before copying the contents of specified file.

Syntax

```
copy <source-url> local-radius-user-db [add|replace]
```

Parameter	Description
<source-url>	URL of the source file.
add	Add file contents to local RADIUS server user database.
replace	Replace current local RADIUS server user database with file contents.

Default When no copy method is specified with this command the replace option is applied.

Mode Privileged Exec

Examples To replace the current local RADIUS server user data to the contents of http://datahost/user.csv, use the following command:

```
awplus# copy http://datahost/user.csv local-radius-user-db
```

To add the contents of http://datahost/user.csv to the current local RADIUS server user database, use the following command:

```
awplus# copy http://datahost/user.csv local-radius-user-db add
```

Related commands

copy fdb-radius-users (to file)
copy local-radius-user-db (to file)

copy local-radius-user-db (to file)

Use this command to copy the local RADIUS server user data to a file. The output file produced is CSV (Comma Separated Values) format.

Syntax `copy local-radius-user-db {flash|nvs|card|tftp|scp|<destination-url>}`

Parameter	Description
`flash`	Copy to flash memory.
`nvs`	Copy to NVS memory.
`card`	Copy to SD card.
`tftp`	Copy to TFTP destination.
`scp`	Copy to SCP destination.
`<destination-url>`	URL of the Destination file.

Mode Privileged Exec

Example Copy the current local RADIUS server user data to http://datahost/user.csv.

```
awplus# copy local-radius-user-db http://datahost/user.csv
```

Related Commands copy fdb-radius-users (to file)
copy local-radius-user-db (from file)

crypto pki enroll local

Use this command to obtain a system certificate from the Local CA (Certificate Authority).

Use the no variant of this command to delete system certificates created by a Local CA (Certificate Authority).

Syntax

```
crypto pki enroll local
no crypto pki enroll local
```

Default The system certificate is not available until this command is issued.

Mode Global Configuration

Example The following command obtains the system certificate from the Local CA (Certificate Authority).

```
awplus# configure terminal
awplus(config)# crypto pki enroll local
```

The following command deletes the system certificate created by the Local CA (Certificate Authority).

```
awplus# configure terminal
awplus(config)# no crypto pki enroll local
```

Related Commands

crypto pki trustpoint local
group

crypto pki enroll local local-radius-all-users

Use this command to create certificates for all users registered in the local RADIUS server. These certificates are created by the Local Certificate Authority (CA) on the switch.

Syntax `crypto pki enroll local local-radius-all-users`

Default By default, there are no certificates for users in the local RADIUS server.

Mode Global Configuration

Example The following command obtains the local RADIUS server certificates for the user from the Local CA (Certificate Authority).

```
awplus# configure terminal
awplus(config)# crypto pki enroll local local-radius-all-users
```

Related Commands crypto pki trustpoint local
show crypto pki certificates

crypto pki enroll local user

Use this command to obtain a local user certificate from the Local CA (Certificate Authority).

Use the no variant of this command to delete user certificates created by the Local CA (Certificate Authority).

Syntax

```
crypto pki enroll local user <user-name>
no crypto pki enroll local user <user-name>
```

Parameter	Description
<user-name>	User name.

Default By default, there is no user certificate.

Mode Global Configuration

Example The following command obtains Tom's certificate from the Local CA (Certificate Authority).

```
awplus# configure terminal
awplus(config)# crypto pki enroll local user Tom
```

The following command deletes Tom's certificates created by the Local CA (Certificate Authority):

```
awplus# configure terminal
awplus(config)# no crypto pki enroll local user Tom
```

Related Commands

crypto pki trustpoint local
show crypto pki certificates

crypto pki export local pem

Use this command to export the certificate associated with the Local CA to a PEM format file.

Syntax `crypto pki export local pem url <url>`

Parameter	Description
<url>	URL string.

Mode Global Configuration

Example The following command exports the Local CA certificate to a PEM format file.

```
awplus# configure terminal
awplus(config)# crypto pki export local pem url tftp://
192.168.1.1/cacert.pem
```

Related Commands crypto pki enroll local

crypto pki export local pkcs12

Use this command to export a specified certificate to a PKCS12 format file.

This command cannot be used for exporting certificates for the local system.

Syntax `crypto pki export local pkcs12 <user-name> <destination-url>`

Parameter	Description
<user-name>	User name.
<destination-url>	Destination URL string.

Mode Global Configuration

Example The following commands exports a certificate for a user named client to a PKCS12 format file.

```
awplus# configure terminal
awplus(config)# crypto pki export local pkcs12 client tftp://
192.168.1.1/cacert.pem
```

To export Tom's certificate to PKSC12 format file, use the commands:

```
awplus# configure terminal
awplus(config)# crypto pki export local pksc12 Tom tftp://
192.168.1.1/tom.pfx
```

Related Commands crypto pki enroll local

crypto pki trustpoint local

Use this command to declare the Local CA (Certificate Authority) as the trustpoint that the system uses. The ca-trustpoint configuration mode is available after this command is issued.

Use the no variant of this command to delete all information and certificates associated with Local CA as the trustpoint.

Syntax

```
crypto pki trustpoint local
no crypto pki trustpoint local
```

Default Local CA is not a trustpoint.

Mode Global Configuration

Examples Use the following commands to declare the Local CA as the trustpoint.

```
awplus# configure terminal
awplus(config)# crypto pki trustpoint local
```

Use the following commands to delete all information and certificates associated with the Local CA.

```
awplus# configure terminal
awplus(config)# no crypto pki trustpoint local
```

To create a client certificate for all users registered to the local RADIUS server, use the following commands:

```
awplus(config)# crypto pki trustpoint local
awplus(ca-trust-point)# exit
awplus(config)# crypto pki enroll local alternative
```

Related Commands

crypto pki enroll local
show crypto pki trustpoints

debug crypto

Use this command to enable Public Key Infrastructure (PKI) debugging. When PKI debugging is enabled, the PKI module starts generating diagnostic messages to the system log.

Use the no variant of this command to disable Public Key Infrastructure (PKI) debugging. When PKI debugging is disabled, the PKI module stops generating diagnostic messages to the system log.

Syntax

```
debug crypto pki
no debug crypto pki
```

Default PKI debugging is disabled by default

Mode Privileged Exec

Example To enable the PKI debugging facility, use the command:

```
awplus# debug crypto pki
```

To disable the PKI debugging facility, use the command:

```
awplus# no debug crypto pki
```

domain-style

Use this command to enable a specified domain style on the local RADIUS server. The local RADIUS server decodes the domain portion of a username login string when this command is enabled.

Use the no variant of this command to disable the specified domain style on the local RADIUS server.

Syntax `domain-style {suffix-atsign|ntdomain}`

Parameter	Description
`suffix-atsign`	Enable at sign "@" delimited suffix style, i.e. "user@domain".
`ntdomain`	Enable NT domain style, i.e. "domain\user".

Default This feature is disabled by default.

Mode RADIUS Server

Usage When both domain styles are enabled, the first domain style configured has the highest priority. A username login string is matched against the first domain style enabled. Then, if the username login string is not decoded, it is matched against the second domain style enabled.

Example To enable NT domain style on the local RADIUS server, use the commands:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# domain-style ntdomain
```

To disable NT domain style on the local RADIUS server, use the commands:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# no domain-style ntdomain
```

Related Commands server enable

egress-vlan-id

Use this command to configure the standard RADIUS attribute 'Egress-VLANID (56)' for the local RADIUS Server user group.

Use the no variant of this command to remove the Egress-VLANID attribute from the local RADIUS server user group.

Syntax

```
egress-vlan-id <vid> [tagged|untagged]
no egress-vlan-id
```

Parameter	Description
<vid>	The VLAN identifier to be used for the Egress VLANID attribute, in the range 1 to 4094.
`tagged`	Set frames on the VLAN as tagged. This sets the tag indication field to indicate that all frames on this VLAN are tagged.
`untagged`	Set all frames on the VLAN as untagged. This sets the tag indication field to indicate that all frames on this VLAN are untagged.

Default By default, no Egress-VLANID attributes are configured.

Mode RADIUS Server Group Configuration

Usage When a Voice VLAN is configured for dynamic VLAN allocation (switchport voice vlan command on page 17.28), the RADIUS server must be configured to send the VLAN information when an IP phone is successfully authenticated. Use either the egress-vlan-id command or the egress-vlan-name command on page 73.20, and specify the tagged parameter.

Examples To set the 'Egress-VLANID' attribute for the NormalUsers local RADIUS server user group to VLAN identifier 200, with tagged frames, use the commands:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# group NormalUsers
awplus(config-radsrv-group)# egress-vlan-id 200 tagged
```

To remove the 'Egress-VLANID' attribute for the NormalUsers local RADIUS server user group, use the commands:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# group NormalUsers
awplus(config-radsrv-group)# no egress-vlan-id
```

Related Commands
attribute
egress-vlan-name
switchport voice vlan

egress-vlan-name

Use this command to configure the standard RADIUS attribute 'Egress-VLAN-Name (58)' for the local RADIUS server user group.

Use the no variant of this command to remove the Egress-VLAN-Name attribute from the local RADIUS server user group.

Syntax

```
egress-vlan-name <vlan-name> [tagged|untagged]
no egress-vlan-name
```

Parameter	Description
<*vlan-name*>	The VLAN name to be configured as the Egress-VLAN-Name attribute.
`tagged`	Set frames on the VLAN as tagged. This sets the tag indication field to indicate that all frames on this VLAN are tagged.
`untagged`	Set all frames on the VLAN as untagged. This sets the tag indication field to indicate that all frames on this VLAN are untagged.

Default By default, no Egress-VLAN-Name attributes are configured.

Mode RADIUS Server Group Configuration

Usage When a Voice VLAN is configured for dynamic VLAN allocation (switchport voice vlan command on page 17.28), the RADIUS server must be configured to send the VLAN information when an IP phone is successfully authenticated. Use either the egress-vlan-id command on page 73.19 or the egress-vlan-name command, and specify the tagged parameter.

Examples To configure the 'Egress-VLAN-Name' attribute for the RADIUS server user group NormalUsers with the VLAN name 'vlan2' and all frames on this VLAN tagged, use the commands:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# group NormalUsers
awplus(config-radsrv-group)# egress-vlan-name vlan2 tagged
```

To delete the 'Egress-VLAN-Name' attribute for the NormalUsers group, use the commands:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# group NormalUsers
awplus(config-radsrv-group)# no egress-vlan-name
```

Related Commands
attribute
egress-vlan-id
switchport voice vlan

group

Use this command to create a local RADIUS server user group, and enter local RADIUS Server User Group Configuration mode.

Use the no variant of this command to delete the local RADIUS server user group.

Syntax

```
group <user-group-name>
no group <user-group-name>
```

Parameter	Description
<user-group-name>	User group name string.

Mode RADIUS Server

Example The following command creates the user group NormalUsers.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# group NormalUsers
```

The following command deletes user group NormalUsers.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# no group NormalUsers
```

Related Commands

user (RADIUS server)
show radius local-server user
vlan (RADIUS server)

nas

This command adds a client device (the Network Access Server or the NAS) to the list of devices that are able to send authentication requests to the local RADIUS server. The NAS is identified by its IP address and a shared secret (also referred to as a shared key) must be defined that the NAS will use to establish its identity.

Use the no variant of this command to remove a NAS client from the list of devices that are allowed to send authentication requests to the local RADIUS server.

Syntax

```
nas <ip-address> key <nas-keystring>
no nas <ip-address>
```

Parameter	Description
<ip-address>	RADIUS NAS IP address.
<nas-keystring>	NAS shared keystring.

Mode RADIUS server

Example The following commands add the NAS with an IP address of `192.168.1.2` to the list of clients that may send authentication requests to the local RADIUS server. Note the shared key that this NAS will use to establish its identify is `NAS_PASSWORD`.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# nas 192.168.1.2 key NAS_PASSWORD
```

The following commands remove the NAS with an IP address of `192.168.1.2` from the list of clients that are allowed to send authentication requests to the local RADIUS server:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# no nas 192.168.1.2
```

Related Commands show radius local-server nas

radius-server local

Use this command to navigate to the Local RADIUS server configuration mode `(config-radsrv)` from the Global Configuration mode `(config)`.

Syntax `radius-server local`

Mode Global Configuration

Example Local RADIUS Server commands are available from `config-radsrv` configuration mode. To change mode from User Exec mode to the Local RADIUS Server mode (config-radsrv), use the commands:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)#
```

Output

```
awplus(config)#radius-server local
Creating Local CA repository.....OK
Enrolling Local System to local trustpoint..OK
awplus(config-radsrv)#
```

Related Commands
server enable
show radius local-server group
show radius local-server nas
show radius local-server statistics
show radius local-server user

server auth-port

Use this command to change the UDP port number for local RADIUS server authentication.

Use the no variant of this command to reset the RADIUS server authentication port back to the default.

Syntax

```
server auth-port <1-65535>
no server auth-port
```

Parameter	Description
<1-65535>	UDP port number.

Default The default local RADIUS server UDP authentication port number is 1812.

Mode RADIUS Server

Example The following commands set the RADIUS server authentication port to 10000.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# server port 10000
```

The following commands reset the RADIUS server authentication port back to the default UDP port of 1812.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# no server port
```

Related Commands

server enable
show radius local-server statistics

server enable

This command enables the local RADIUS server. The local RADIUS server feature is started immediately when this command is issued.

The no variant of this command disables local RADIUS server. When this command is issued, the local RADIUS server stops operating.

Syntax

```
server enable
no server enable
```

Default The local RADIUS server is disabled by default and must be enabled for use with this command.

Mode RADIUS Server

Examples To enable the local RADIUS server, use the following commands:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# server enable
```

To disable the local RADIUS server, use the command:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# no server enable
```

Related Commands

server auth-port
show radius local-server statistics

show crypto pki certificates

Use this command to display certificate information for Local CA and Local System certificates.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show crypto pki certificates [local-ca|local]`

Parameter	Description
`local-ca`	Local CA certificate.
`local`	Local system certificate.

Mode User Exec and Privileged Exec

Example The following command displays Local CA (Certificate Authority) certificate information.

```
awplus# show crypto pki certificates local-ca
```

The following command displays Local System certificate information.

```
awplus# show crypto pki certificates local
```

The following command displays information for all Local CA and Local System certificates.

```
awplus# show crypto pki certificates
```

Output

Figure 73-1: Example output from the **show crypto pki certificates** command showing Local System and Local CA certificates

```
awplus#show crypto pki certificates
Certificate: Local System
    Data:
        Version: 3 (0x2)
        Serial Number: 4 (0x4)
        Signature Algorithm: sha1WithRSAEncryption
        Issuer: O=Allied-Telesis, CN=AlliedwarePlusCA
        Validity
            Not Before: Oct  8 07:50:55 2009 GMT
            Not After : Oct  6 07:50:55 2019 GMT
        Subject: O=Allied-Telesis, CN=Tom
Certificate: Local CA
    Data:
        Version: 3 (0x2)
        Serial Number: 0 (0x0)
        Signature Algorithm: sha1WithRSAEncryption
        Issuer: O=Allied-Telesis, CN=AlliedwarePlusCA
        Validity
            Not Before: Oct  8 07:55:55 2009 GMT
            Not After : Oct  6 07:55:55 2019 GMT
        Subject: O=Allied-Telesis, CN=Tom
```

Table 73-1: Parameters in the output of the **show crypto pki certificates** command

Parameter	Description
`Certificate`	Certificate name
`Version`	Protocol version
`Serial Number`	Serial number of the certificate
`Signature Algorithm`	Algorithm used for the certificate signature
`Issuer`	Subject of issuer creating the certificate
`Validity`	Validity period
`Subject`	Subject of the certificate

Related Commands crypto pki enroll local

show crypto pki certificates local-radius-all-users

Use this command to display certificate information for local RADIUS server users.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show crypto pki certificates local-radius-all-users`

Mode User Exec and Privileged Exec

Example The following command displays information of all local RADIUS server user certificates.

```
awplus# show crypto pki certificates local-radius-all-users
```

Output

Figure 73-2: Example output from the **show crypto pki certificates local-radius-all-users** command

```
awplus#show crypto pki certificates local-radius-all-users
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number: 2 (0x2)
        Signature Algorithm: sha1WithRSAEncryption
        Issuer: O=Allied-Telesis, CN=AlliedwarePlusCA
        Validity
            Not Before: Oct  8 07:50:55 2009 GMT
            Not After : Oct  6 07:50:55 2019 GMT
        Subject: O=Allied-Telesis, CN=Tom
```

Table 73-2: Parameters in the output of the **show crypto pki certificates local-radius-all-users** command

Parameter	Description
`Certificate`	Certificate name
`Version`	Protocol version
`Serial Number`	Serial number of the certificate
`Signature Algorithm`	Algorithm used for the certificate signature
`Issuer`	Subject of issuer creating the certificate
`Validity`	Validity period
`Subject`	Subject of the certificate

Related Commands crypto pki enroll local local-radius-all-users

show crypto pki certificates user

Use this command to display certificate information for a specified local RADIUS server user.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax

```
show crypto pki certificates user [<user-name>]
```

Parameter	Description
<user-name>	User name.

Mode

User Exec and Privileged Exec

Example

The following command displays Tom's certificate information.

```
awplus# show crypto pki certificates user Tom
```

Output

Figure 73-3: Example output from the **show crypto pki certificates user** command to show certificate information for user Tom

```
awplus#show crypto pki certificates user Tom
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number: 2 (0x2)
        Signature Algorithm: sha1WithRSAEncryption
        Issuer: O=Allied-Telesis, CN=AlliedwarePlusCA
        Validity
            Not Before: Oct  8 07:50:55 2009 GMT
            Not After : Oct  6 07:50:55 2019 GMT
        Subject: O=Allied-Telesis, CN=Tom
```

Table 73-3: Parameters in the output of the **show crypto pki certificates user** command

Parameter	Description
`Certificate`	Certificate name
`Version`	Protocol version
`Serial Number`	Serial number of the certificate
`Signature Algorithm`	Algorithm used for the certificate signature
`Issuer`	Subject of issuer creating the certificate
`Validity`	Validity period
`Subject`	Subject of the certificate

Related Commands

crypto pki enroll local user

show crypto pki trustpoints

Use this command to display trustpoint information.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax

```
show crypto pki trustpoints
```

Mode

User Exec and Privileged Exec

Example

The following command displays trustpoint information.

```
awplus# show crypto pki trustpoint
```

Output

Figure 73-4: Example output from the **show crypto pki trustpoints** command

```
Trustpoint local:
Subject Name:
CN = AlliedwarePlusCA
o = Allied-Telesis
Serial Number:0C
```

Table 73-4: Parameters in the output of the **show crypto pki trustpoints** command

Parameter	Description
`Subject Name`	CA certificate subject.
`Serial Number`	Current serial number of CA.

Related Commands

crypto pki enroll local

show radius local-server group

Use this command to display information about the local RADIUS server user group.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax

```
show radius local-server group [<user-group-name>]
```

Parameter	Description
<user-group-name>	User group name string.

Mode User Exec and Privileged Exec

Example The following command displays Local RADIUS server user group information.

```
awplus# show radius local-server group
```

Output

Figure 73-5: Example output from the **show radius local-server group** command

```
Group-Name          Vlan
-------------------------------------------------------------
NetworkOperators    ManagementNet
NormalUsers         CommonNet
```

Table 73-5: Parameters in the output of the **show radius local-server group** command

Parameter	Description
Group-Name	Group name.
Vlan	VLAN name assigned to the group.

Related Commands group

show radius local-server nas

Use this command to display information about NAS (Network Access Servers) registered to the local RADIUS server.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show radius local-server nas [<ip-address>]`

Parameter	Description
`<ip-address>`	Specify NAS IP address for show output.

Mode User Exec and Privileged Exec

Example The following command displays NAS information.

```
awplus# show radius local-server nas
```

Output

Figure 73-6: Example output from the **show radius local-server nas** command

```
NAS-Address     Shared-Key
-----------------------------------------------------------
127.0.0.1       awplus-local-radius-server
```

Table 73-6: Parameters in the output of the **show radius local-server nas** command

Parameter	Description
`NAS-Address`	IP address of NAS.
`Shared-Key`	Shared key used for RADIUS connection.

Related Commands nas

show radius local-server statistics

Use this command to display statistics about the local RADIUS server.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax

```
show radius local-server statistics
```

Mode

User Exec and Privileged Exec

Usage

Both unknown usernames and invalid passwords will display as failed logins in the show output.

Example

The following command displays Local RADIUS server statistics.

```
awplus# show radius local-server statistics
```

Output

Figure 73-7: Example output from the **show radius local-server statistics** command

```
Server status  : Run (administrative status is enable)

show radius local-server user

Use this command to display information about the local RADIUS server user.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax

```
show radius local-server user [<user-name>]
show radius local-server user <user-name> format csv
```

Parameter	Description
`<user-name>`	RADIUS user name. If no user name is specified, information for all users is displayed.
`format`	File format.
`csv`	Comma separated value format.

Mode User Exec and Privileged Exec

Usage You can send output from any show command, including the CSV format output from this command, to a file. See "Controlling "show" Command Output" on page 1.41.

Example The following command displays Local RADIUS server user information for user Tom.

```
awplus# show radius local-server user Tom
```

Figure 73-8: Example output from the show radius local-server user command

```
User-Name   Password   Group          Vlan
-----------------------------------------------------------------
Tom         abcd       NetworkOperators ManagementNet
```

The following command displays all Local RADIUS server information for all users.

```
awplus# show radius local-server user
```

The following command displays Local RADIUS server user information for TOM in CSV format.

```
awplus# show radius local-server user Tom format csv
```

Figure 73-9: Example output from the show radius local-server user csv command

```
true,"NetworkOperators","Tom",
"abcd",0,2099/01/
01,1,"","","ManagementNet",false,3600,false,0,"",false,"
```

Table 73-7: Parameters in the output from the **show radius local-server user** command

Parameter	Description
`User-Name`	User name.
`Password`	User password.
`Group`	Group name assigned to the user.
`Vlan`	VLAN name assigned to the user.

Related Commands

group
user (RADIUS server)

user (RADIUS server)

Use this command to register a user to the local RADIUS server.

Use the no variant of this command to delete a user from the local RADIUS server.

Syntax

```
user <radius-user-name> [encrypted] password <user-password>
    [group <user-group>]

no user <radius-user-name>
```

Parameter	Description
<radius-user-name>	RADIUS user name. This can also be a MAC address in the IEEE standard format of HH-HH-HH-HH-HH-HH if you are configuring MAC authentication to use local RADIUS server.
encrypted	Specifies that the password is being entered in its encrypted form, so that it is not further encrypted. When creating a new user, enter the password in plaintext, and do not use the encrypted parameter. Use the encrypted parameter only when referring to a user that has previously been created. For instance, when adding an existing user from another RADIUS server, use the encrypted parameter, and enter the encrypted version of the password that appears in the output of show commands for the user.
<user-password>	User password. This can also be a MAC address in the IEEE standard format of HH-HH-HH-HH-HH-HH if you are configuring MAC authentication to use local RADIUS server.
group	Specify the group for the user.
<user-group>	User group name.

Mode RADIUS Server

Usage RADIUS user names cannot contain question mark (?), space ( ), or quote (“ “) characters. RADIUS user names containing the below characters cannot use certificate authentication:

```
/ \ ' $ & ( ) * ; < > ` |
```

Certificates cannot be created and exported for RADIUS user names that contain the above characters. We advise you to avoid using these characters in RADIUS user names if you need to use certificate authentication, because you will not be able to create and export certificates.

You also can use the IEEE standard format hexadecimal notation (HH-HH-HH-HH-HH-HH) to specify a supplicant MAC address to configure the user name and user password parameters to use local RADIUS server for MAC Authentication. See the Sample MAC Authentication Configuration in Chapter 66, AAA Introduction and Configuration. See also the command user 00-db-59-ab-70-37 password 00-db-59-ab-70-37 as shown in the command examples.

Examples The following commands add user `Tom` to the local RADIUS server and sets his password to `QwerSD`.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# user Tom password QwerSD
```

The following commands add user `Tom` to the local RADIUS server user group NormalUsers and sets his password `QwerSD`.

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# user Tom password QwerSD group
NormalUsers
```

The following commands remove user Tom from the local RADIUS server:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# no user Tom
```

The following commands add the supplicant MAC address 00-d0-59-ab-70-37 to the local RADIUS server:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# user 00-db-59-ab-70-37 password 00-db-
59-ab-70-37
```

The following commands remove the supplicant MAC address 00-d0-59-ab-70-37 from the local RADIUS server:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# no user 00-db-59-ab-70-37
```

Related Commands group
show radius local-server user

vlan (RADIUS server)

Use this command to set the VLAN ID or name for the local RADIUS server user group. The VLAN information is used for authentication with the dynamic VLAN feature.

Use the no variant of this command to clear the VLAN ID or VLAN name for the local RADIUS server user group.

Syntax

```
vlan {<vid>|<vlan-name>}
no vlan
```

Parameter	Description
<vid>	VLAN ID.
<vlan-name>	VLAN name.

Default VLAN information is not set by default.

Mode RADIUS Server Group

Example The following commands set VLAN ID 200 to the group named NormalUsers:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# group NormalUsers
awplus(config-radsrv-group)# vlan 200
```

The following commands remove VLAN ID 200 from the group named NormalUsers:

```
awplus# configure terminal
awplus(config)# radius-server local
awplus(config-radsrv)# group NormalUsers
awplus(config-radsrv-group)# no vlan
```

Introduction

This chapter describes how the Secure Shell protocol is implemented in the AlliedWare Plus™ Operating System. It covers:

- Support for Secure Shell.
- Configuring your device as a Secure Shell server and client.
- Using Secure Shell to manage your device.

The AlliedWare Plus™ OS supports SSH version 2 and SSH version 1.5, making it backwards compatible with SSH version 1.

Secure management is important in modern networks, as the ability to easily and effectively manage switches and routers, and the requirement for security, are two almost universal requirements. Protocols such as Telnet and rlogin allow you to manage devices remotely, but can have serious security problems, such as relying on reusable plaintext passwords that are vulnerable to wiretapping or password guessing. The Secure Shell (SSH) protocol is superior to these protocols by providing encrypted and strongly authenticated remote login sessions.

SSH provides sessions between a host running a SSH server and a machine with a SSH client. The AlliedWare Plus™ OS includes both a SSH server and a SSH client to enable you to securely—with the benefit of cryptographic authentication and encryption—manage your devices over an insecure network:

- SSH replaces Telnet for remote terminal sessions; SSH is strongly authenticated and encrypted.
- Remote command execution allows you to send commands to a device securely and conveniently, without requiring a terminal session on the device.
- SSH allows you to connect to another host from your switch or router.

The AlliedWare Plus™ OS supports Secure Copy (SCP) and SSH File Transfer Protocol (SFTP). Both these protocols allow you to securely copy files between your device and remote machines. SFTP provides additional features from SCP, such as allowing you to manipulate the remote files, and halt or resume file transfers without closing the session.

Secure Shell on the AlliedWare Plus OS

The AlliedWare Plus™ OS implementation of SSH is compatible with the following RFCs and Internet Drafts:

- The Secure Shell (SSH) Protocol Architecture (RFC 4251)
- The Secure Shell (SSH) Authentication Protocol (RFC 4252)
- The Secure Shell (SSH) Transport Layer Protocol (RFC 4253)
- The Secure Shell (SSH) Connection Protocol (RFC 4254)
- The SSH (Secure Shell) Remote Login Protocol (draft-ylonen-ssh-protocol-00.txt)
- SSH File Transfer Protocol (draft-ietf-secsh-filexfer-13.txt)

Secure Shell supports the following features for both SSH version 2 and SSH version 1.5:

- Inbound SSH connections (server mode) and outbound SSH connections (client mode).
- File loading to and from remote machines using Secure Copy, using either the SSH client or SSH server mode.
- RSA public keys with lengths of 768–32768 bits, and DSA keys with lengths of 1024 bits. Keys are stored in a format compatible with other SSH implementations, and mechanisms are provided to copy keys to and from your device.
- Secure encryption, such as Triple DES and Blowfish.
- Remote non-interactive shell that allows arbitrary commands to be sent securely to your device, possibly automatically.
- Compression of Secure Shell traffic.
- Tunnelling of TCP/IP traffic.

Secure Shell supports the following features for SSH version 2 only:

- File loading from remote machines using SSH File Transfer Protocol (SFTP).
- A login banner on the SSH server, that displays when SSHv2 clients connect to the server.

Configuring the SSH Server

This section provides instructions on:

- Creating a Host Key
- Enabling the Server
- Modifying the Server
- Validating the Server Configuration
- Adding SSH Users
- Authenticating SSH Users
- Adding a Login Banner
- Monitoring the Server and Managing Sessions
- Debugging the Server

Creating a Host Key

The SSH server uses either an RSA or DSA host key to authenticate itself with SSH clients. This key must be configured before the SSH server can operate. If no host key exists, you cannot start the SSH server.

Once created, the host key is stored securely on the device. To generate a host key for the SSH server, use the command:

```
awplus(config)# crypto key generate hostkey {dsa|rsa|rsa1}
                [<768-32768>]
```

This command has two parameters for creating RSA keys. The rsa parameter creates a host key for SSH version 2 sessions only. To create a host key for SSH version 1 sessions, use the rsa1 parameter.

To destroy a host key, use the command:

```
awplus(config)# crypto key destroy hostkey {dsa|rsa|rsa1}
```

To display a host key stored on your device, use the command:

```
awplus(config)# show crypto key hostkey [dsa|rsa|rsa1]
```

Enabling the Server

You must enable the SSH server before connections from SSH, SCP, and SFTP clients are accepted. When the SSH server is disabled it rejects connections from SSH clients. The SSH server is disabled by default on your device.

To enable the SSH server, use the command:

```
awplus(config)# service ssh [ip|ipv6]
```

To disable the SSH server, use the command:

```
awplus(config)# no service ssh [ip|ipv6]
```

When enabled, the SSH server allows SCP and SFTP sessions by default. To disable these services, use the commands:

```
awplus(config)# no ssh server scp

awplus(config)# no ssh server sftp
```

This allows you to reject SCP or SFTP file transfer requests, while still allowing Secure Shell connections. To re-enable SCP and SFTP services, use the command:

```
awplus(config)# ssh server scp

awplus(config)# ssh server sftp
```

Modifying the Server

To modify the SSH version that the server supports, or the TCP port that the server listens to for incoming sessions, use the command:

```
awplus(config)# ssh server {[v1v2|v2only]|<1-65535>}
```

The server listens on port 22 for incoming sessions, and supports both SSH version 2 and SSH version 1, by default.

To modify session and login timeouts on the SSH server, and the number of unauthenticated connections the server allows, use the command:

```
awplus(config)# ssh server {[session-timeout <0-3600>]
               [login-timeout <1-600>]
               [max-startups <1-128>]}
```

The SSH server waits 60 seconds for a client to authenticate itself, by default. You can alter this waiting time by using the login-timeout parameter. If the client is still not authenticated after the set timeout, then the SSH server disconnects the session.

The SSH server only allows only 10 unauthenticated SSH sessions at any point in time, by default. You can modify the number of unauthenticated sessions it allows, by using the max-startups parameter.

Once a client has authenticated, the SSH session does not time out, by default. Use the session-timeout parameter to set a maximum time period the server waits before deciding that a session is inactive and terminating it

For example, to set the session timeout to 600 seconds, the login timeout to 30 seconds, and the maximum number of concurrent unauthenticated sessions to 5, use the command:

```
awplus(config)# ssh server session-timeout 600 login-timeout
               30 max-startups 5
```

To remove the configured session timeout, login timeout, or maximum startups, use the command:

```
awplus(config)# no ssh server session-timeout login-timeout
               max-startups
```

Validating the Server Configuration

To validate the SSH server configuration, use the command:

```
awplus(config)# show running-config ssh
```

Adding SSH Users

The SSH server requires you to register SSH users. Users that are not registered cannot access the SSH server. Ensure first that you have defined the user in the Authorized User Database of your device. To add a new user, use the command:

```
awplus(config)# username USERNAME (privilege 1-15) password
                PASSWORD
```

To register a user with the SSH server, use the command:

```
awplus(config)# ssh server allow-users <username-pattern>
                [<hostname-pattern>]
```

Registered entries can contain just the username, or the username with some host details, such as an IP address range. Additionally you can specify a range of users or hostname details by using an asterisk to match any string of characters. For example, to allow any user from the IP range 192.168.1.1 to 192.168.1.255, use the command:

```
awplus(config)# ssh server allow-users * 192.168.1.*
```

To display the list of allowed users, use the command:

```
awplus# show ssh server allow-users
```

To delete an entry from the list of allowed users, use the command:

```
awplus(config)# no ssh server allow-users <username-pattern>
                [<hostname-pattern>]
```

The SSH server also contains a list of denied users. The server checks all incoming sessions against this list and denies any matching session, regardless of whether the session matches an entry in the allowed users list. To add an entry to the list of denied users, use the command:

```
awplus(config)# ssh server deny-users <username-pattern>
                [<hostname-pattern>]
```

This allows you to deny specific users from a range of allowed users. For example, to deny a user with the IP address 192.168.1.12, use the command:

```
awplus(config)# ssh server deny-users * 192.168.1.12
```

To display the database of denied users, use the command:

```
awplus# show ssh server deny-users
```

To delete a client from the database of denied users, use the command:

```
awplus(config)# no ssh server deny-users <username-pattern>
                [<hostname-pattern>]
```

Authenticating SSH Users

SSH users can use either their password or public key authentication to authenticate themselves with the SSH server. To use public key authentication, copy the user's public key file from their client device to the SSH server. To associate the key with a user, use the command:

```
awplus(config)# crypto key pubkey-chain userkey <username>
                [<filename>]
```

For example, to associate the file key.pub with the user "langley", use the command:

```
awplus(config)# crypto key pubkey-chain userkey langley
                key.pub
```

To add a key as text into the terminal for user "geoff", first enter the command:

```
awplus(config)# crypto key pubkey-chain userkey geoff
```

then paste or type the key in as text.

You can add multiple keys for the same user. To display the list of public keys associated with a user, use the command:

```
awplus(config)# show crypto key pubkey-chain userkey
                <username> [<1-65535>]
```

The <1-65535> parameter allows you to display an individual key.

To delete a key associated with a user from your device, use the command:

```
awplus(config)# no crypto key pubkey-chain userkey
                <username> <1-65535>
```

Adding a Login Banner

You can add a login banner to the SSH server for sessions with SSH version 2 clients. The server displays the banner to clients before the login prompt. To set the login banner's message, use the command:

```
awplus(config)# banner login
```

then enter your message and use Ctrl+D to finish.

To view the configured login banner, use the command:

```
awplus# show banner login
```

To remove the configured message for the login banner, use the command:

```
awplus(config)# no banner login
```

Monitoring the Server and Managing Sessions

To display the current status of the SSH server, use the command:

```
awplus# show ssh server
```

To display the current status of SSH sessions on your device, use the command:

```
awplus# show ssh
```

Note that this displays both SSH server and SSH client sessions that your Allied Telesis device is running. Use this command to view the unique identification number assigned to each incoming or outgoing SSH session. You need the ID number when terminating a specific session from your device.

To terminate a session, or all sessions, use the command:

```
awplus# clear ssh {<1-65535>|all}
```

Debugging the Server

Information which may be useful for troubleshooting the SSH server is available using the SSH debugging function. You can enable server debugging while the SSH server is functioning. Use the command:

```
awplus# debug ssh server [brief|full]
```

To disable SSH server debugging, use the command:

```
awplus# no debug ssh server
```

Configuring the SSH Client

This section provides instructions on:

- Modifying the Client
- Adding SSH Servers
- Authenticating with a Server
- Connecting to a Server and Running Commands
- Copying files to and from the Server
- Debugging the Client

Modifying the Client

You can configure a selection of variables when using the SSH client. Note that the following configuration commands apply only to client sessions initiated after the command. The configured settings are not saved; after you have logged out from the SSH client, the client returns to using the default settings. Use the command:

```
awplus(config)# ssh client {port <1-65535>|version {1|2}|
                session-timeout <0-3600>|connect-timeout
                <1-600>}
```

The SSH client uses TCP port 22, by default. You can change the TCP port for the remote SSH server by using the port parameter.

The client supports both SSH version 1 and version 2 sessions, by default. To change the SSH client to only use a specific SSH version for sessions, for example SSH version 1, use the version parameter.

The client terminates sessions that are not established after 30 seconds, by default. You can change this time period by using the session-timeout parameter.

Once the client has authenticated with a server, the client does not time out the SSH session, by default. Use the session-timeout parameter to set a maximum time period the client waits before deciding that a session is inactive and terminating the session.

To modify the SSH client so that it uses port 2000 for sessions, and supports only SSH version 1 connections, use the command:

```
awplus(config# ssh client port 2000 version 1
```

To modify the SSH client so that unestablished sessions time out after 60 seconds, and inactive sessions time out after 100 seconds, use the command:

```
awplus(config)# ssh client session-timeout 100 connect-timeout
                100
```

To remove the configured port, SSH version, session timeout, and connection timeout settings, use the command:

```
awplus(config)# no ssh client port version session-timeout
                connect-timeout
```

Adding SSH Servers

SSH servers identify themselves using a host key (see "Creating a Host Key" on page 74.4). Before the SSH client establishes a session with a SSH server, it confirms that the host key sent by the server matches its database entry for the server. If the database does not contains a host key for the server, then the SSH client requires you to confirm that the host key sent from the server is correct.

To add an SSH server to the client's database, use the command:

```
awplus# crypto key pubkey-chain knownhosts [vrf
<vrf-name>] [ip|ipv6] <hostname> [rsa|dsa|rsa1]
```

To display the SSH servers in the client's database, use the command:

```
awplus# show crypto key pubkey-chain knownhosts [vrf
<vrf-name>|global] [<1-65535>]
```

To remove an entry in the database, use the command:

```
awplus# no crypto key pubkey-chain knownhosts [vrf
<vrf-name>] <1-65535>
```

Authenticating with a Server

You can authenticate your session with a server by either using a password, or using RSA or DSA public key authentication. To use public key authentication, you must generate a pair of keys, one private and one public, and copy the public key onto the SSH server.

To generate an RSA or DSA set of private and public keys for an SSH user, use the command:

```
awplus(config)# crypto key generate userkey <username> {dsa|
rsa|rsa1} [<768-32768>]
```

You can generate one key of each encryption type per user on your client. When authenticating with an SSH server that supports SSH version 1 only, you must use a key generated by the rsa1 parameter.

To copy the public key onto the SSH server, you must display the key onscreen. To display the public key associated with a user, use the command:

```
awplus# show crypto key userkey <username> [dsa|rsa|
rsa1]
```

To display the public keys set for other users, you must specify their username. Only users with the highest privilege setting can use this command to view the keys of other users.

To delete a public and private pair of keys associated with a user, use the command:

```
awplus(config)# crypto key destroy userkey <username> {dsa|rsa|
rsa1}
```

Connecting to a Server and Running Commands

To connect to a remote SSH server and execute a command, use the command:

```
awplus# ssh [vrf <vrf-name>] [ip|ipv6][{[user
        <username>]|[port <1-65535>]|[version {1|2}]}]
        <hostname> [<line>]
```

By default, the SSH client attempts to use SSH version 2 with the SSH server. If this fails, the client uses SSH version 1.

For example, to connect to the SSH server at 192.168.1.2 as user “john”, and execute the command “show sys”, use the command:

```
awplus# ssh user john 192.168.1.2 “show sys”
```

Copying files to and from the Server

You can use either the SCP or SFTP client to transfer files from a remote SSH server. Use the command:

```
awplus# copy <source-url> <destination-url>
```

For example, to use SFTP to load a file from the SSH server 192.168.1.2, onto the flash memory of your device, use the command:

```
awplus# copy sftp://192.168.1.2/key.pub flash
```

To upload files to the SSH server, you must use SCP. For example, to upload the file bobskey.pub as the user “bob”, use the command:

```
awplus# copy flash:/bobskey.pub scp://bob@192.168.1.2
```

For more information see Chapter 6, Creating and Managing Files.

Debugging the Client

Information which may be useful for troubleshooting the SSH client is available using the SSH debugging function. You can enable client debugging while the SSH client is functioning. Use the command:

```
awplus# debug ssh client [brief|full]
```

To disable SSH client debugging, use the command:

```
awplus# no debug ssh client
```

Chapter 75: Secure Shell (SSH) Configuration

SSH Server Configuration Example.....75.2

SSH Server Configuration Example

This chapter provides a Secure Shell server configuration example. For more information about the SSH server, see Chapter 74, Secure Shell (SSH) Introduction. For detailed information about the commands used to configure the SSH server, see Chapter 76, Secure Shell (SSH) Commands.

The following example configures a SSH server where:

- the SSH server uses RSA encryption
- the SSH server is compatible with both SSH version 1 and version 2 clients
- three SSH users are configured: Manager, John and Asuka. “Manager” can connect from only a defined range of hosts, while “john” and “asuka” can SSH from all hosts
- the SSH users use RSA private and public key authentication

This example shows how to create RSA encryption keys, configure the Secure Shell server, and register users to make Secure Shell connections to your device.

Step 1: Login as a highest Privileged User.

To create the keys and add users, you must login as a privileged user.

Step 2: Create encryption keys.

Two RSA private keys are required before enabling the Secure Shell server for each type of SSH version. Use the commands:

```
awplus# configure terminal
awplus(config)# crypto key generate hostkey rsa
awplus(config)# crypto key generate hostkey rsa1
awplus(config)# exit
```

To verify the key creation, use the command:

```
awplus# show crypto key hostkey
```

Step 3: Enable the Secure Shell server.

Enable Secure Shell on the device using the commands:

```
awplus# configure terminal
awplus(config)# service ssh
```

Modify the SSH server settings as desired. For example, to set the login-timeout to 60, and the session-timeout to 3600, use the commands:

```
awplus(config)# ssh server session-timeout 3600 login-timeout 60
```

To verify the server configuration, use the command:

```
awplus# show ssh
```

Step 4: Create SSH users.

In order to connect and execute commands, you must register users in the SSH user database, and in the User Authentication Database of the device.

To create the users `john` and `asuka` in the User Authentication Database, use the commands:

```
awplus# configure terminal
awplus(config)# username john privilege 15 password secret
awplus(config)# username asuka privilege 15 password
                very-secret
```

To register `john` and `asuka` as SSH clients, use the commands:

```
awplus(config)# ssh server allow-users john
awplus(config)# ssh server allow-users asuka
```

To register “manager” as an SSH client so that can only connect from the IP address 192.168.1.1, use the command:

```
awplus(config)# ssh server allow-users manager 192.168.1.1
```

Step 5: Set up Authentication.

SSH users cannot connect unless the server can authenticate them. There are two ways to authenticate an SSH session: password authentication, and RSA or DSA private/public key authentication. When using password authentication, the user must supply their User Authentication Database password.

To use private/public key authentication, copy the public keys for each user onto the device. To copy the files onto flash from the key directory of an attached TFTP server, use the command:

```
awplus# copy tftp://key/john.pub flash:/john.pub
awplus# copy tftp://key/asuka.pub flash:/asuka.pub
```

To associate the key file with each user, use the command:

```
awplus# configure terminal
awplus(config)# cryto key pubkey-chain userkey john john.pub
awplus(config)# cryto key pubkey-chain userkey asuka asuka.pub
awplus(config)# cryto key pubkey-chain userkey manager
                manager.pub
```

Introduction

This chapter provides an alphabetical reference for commands used to configure Secure Shell (SSH). For more information, see Chapter 74, Secure Shell (SSH) Introduction, and Chapter 75, Secure Shell (SSH) Configuration.

Command List

banner login (SSH)

This command configures a login banner on the SSH server. This displays a message on the remote terminal of the SSH client before the login prompt. SSH client version 1 does not support this banner.

To add a banner, first enter the command banner login, and hit [Enter]. Write your message. You can use any character and spaces. Use Ctrl+D at the end of your message to save the text and re-enter the normal command line mode.

The banner message is preserved if the device restarts.

The no variant of this command deletes the login banner from the device.

Syntax

```
banner login
no banner login
```

Default No banner is defined by default.

Mode Global Configuration

Examples To set a login banner message, use the commands:

```
awplus# configure terminal
awplus(config)# banner login

Type CNTL/D to finish.
... banner message comes here ...
^D
awplus(config)#
```

and enter the message. Use Ctrl+D to finish.

To remove the login banner message, use the commands:

```
awplus# configure terminal
awplus(config)# no banner login
```

Related Commands show banner login

clear ssh

This command deletes Secure Shell sessions currently active on the device. This includes both incoming and outgoing sessions. The deleted sessions are closed. You can only delete an SSH session if you are a system manager or the user who initiated the session. If all is specified then all active SSH sessions are deleted.

Syntax `clear ssh {<1-65535>|all}`

Parameters	Description
`<1-65535>`	Specify a session ID in the range 1 to 65535 to delete a specific session.
`all`	Delete all SSH sessions.

Mode Privileged Exec

Examples To stop the current SSH session 123, use the command:

```
awplus# clear ssh 123
```

To stop all SSH sessions active on the device, use the command:

```
awplus# clear ssh all
```

Related Commands service ssh
ssh

crypto key destroy hostkey

This command deletes the existing public and private keys of the SSH server. Note that for an SSH server to operate it needs at least one set of hostkeys configured before an SSH server is started.

Syntax `crypto key destroy hostkey {dsa|rsa|rsa1}`

Parameters	Description
`dsa`	Deletes the existing DSA public and private keys.
`rsa`	Deletes the existing RSA public and private keys configured for SSH version 2 connections.
`rsa1`	Deletes the existing RSA public and private keys configured for SSH version 1 connections.

Mode Global Configuration

Example To destroy the RSA host key used for SSH version 2 connections, use the commands:

```
awplus# configure terminal
awplus(config)# crypto key destroy hostkey rsa
```

Related Commands crypto key generate hostkey
service ssh

crypto key destroy userkey

This command destroys the existing public and private keys of an SSH user configured on the device.

Syntax `crypto key destroy userkey <username> {dsa|rsa|rsa1}`

Parameters	Description
`<username>`	Name of the user whose userkey you are destroying. The username must begin with a letter. Valid characters are all numbers, letters, and the underscore, hyphen and full stop symbols.
`dsa`	Deletes the existing DSA userkey.
`rsa`	Deletes the existing RSA userkey configured for SSH version 2 connections.
`rsa1`	Deletes the existing RSA userkey for SSH version 1 connections.

Mode Global Configuration

Example To destroy the RSA user key for the SSH user `remoteuser`, use the commands:

```
awplus# configure terminal
awplus(config)# crypto key destroy userkey remoteuser rsa
```

Related Commands
crypto key generate hostkey
show ssh
show crypto key hostkey

crypto key generate hostkey

This command generates public and private keys for the SSH server using either an RSA or DSA cryptography algorithm. You must define a host key before enabling the SSH server. Start SSH server using the service ssh command. If a host key exists with the same cryptography algorithm, this command replaces the old host key with the new key.

This command is not saved in the device configuration. However, the device saves the keys generated by this command in the non-volatile memory.

Syntax

```
crypto key generate hostkey {dsa|rsa|rsa1} [<768-32768>]
```

Parameters	Description
`dsa`	Creates a DSA hostkey. Both SSH version 1 and 2 connections can use the DSA hostkey.
`rsa`	Creates an RSA hostkey for SSH version 2 connections.
`rsa1`	Creates an RSA hostkey for SSH version 1 connections.
<768-32768>	The length in bits of the generated key. The default is 1024 bits.

Default 1024 bits is the default key length. The DSA algorithm supports 1024 bits.

Mode Global Configuration

Examples To generate an RSA host key for SSH version 2 connections that is 2048 bits in length, use the commands:

```
awplus# configure terminal
awplus(config)# crypto key generate hostkey rsa 2048
```

To generate a DSA host key, use the commands:

```
awplus# configure terminal
awplus(config)# crypto key generate dsa
```

Related Commands

crypto key destroy hostkey
service ssh
show crypto key hostkey

crypto key generate userkey

This command generates public and private keys for an SSH user using either an RSA or DSA cryptography algorithm. To use public key authentication, copy the public key of the user onto the remote SSH server.

This command is not saved in the device configuration. However, the device saves the keys generated by this command in the non-volatile memory.

Syntax `crypto key generate userkey <username> {dsa|rsa|rsa1} [<768-32768>]`

Parameters	Description
`<username>`	Name of the user that the user key is generated for. The username must begin with a letter. Valid characters are all numbers, letters, and the underscore, hyphen and full stop symbols.
`dsa`	Creates a DSA userkey. Both SSH version 1 and 2 connections can use a key created with this command.
`rsa`	Creates an RSA userkey for SSH version 2 connections.
`rsa1`	Creates an RSA userkey for SSH version 1 connections.
`<768-32768>`	The length in bits of the generated key. The DSA algorithm supports only 1024 bits. Default: 1024.

Mode Global Configuration

Examples To generate a 2048-bits RSA user key for SSH version 2 connections for the user `bob`, use the commands:

```
awplus# configure terminal
awplus(config)# crypto key generate userkey bob rsa 2048
```

To generate a DSA user key for the user `lapo`, use the commands:

```
awplus# configure terminal
awplus(config)# crypto key generate userkey lapo dsa
```

Related Commands crypto key destroy userkey
show crypto key userkey

crypto key pubkey-chain knownhosts

This command adds a public key of the specified SSH server to the known host database on your switch. The SSH client on your switch uses this public key to verify the remote SSH server.

The key is retrieved from the server. Before adding a key to this database, check that the key sent to you is correct.

If the server's key changes, or if your SSH client does not have the public key of the remote SSH server, then your SSH client will inform you that the public key of the server is unknown or altered.

The no variant of this command deletes the public key of the specified SSH server from the known host database on your device.

Syntax

```
crypto key pubkey-chain knownhosts [vrf <vrf-name>] [ip|ipv6]
   <hostname> [rsa|dsa|rsa1]

no crypto key pubkey-chain knownhosts [vrf <vrf-name>] <1-65535>
```

Parameter	Description
`vrf`	Apply this command to the specified VRF instance.
<vrf-name>	The VRF instance name
`ip`	Keyword used prior to specifying an IPv4 address
`ipv6`	Keyword used prior to specifying an IPv6 address
<hostname>	IPv4/IPv6 address or hostname of a remote server in the format `a.b.c.d` for an IPv4 address, or in the format `x:x::x:x` for an IPv6 address
`rsa`	Specify the RSA public key of the server to be added to the known host database.
`dsa`	Specify the DSA public key of the server to be added to the known host database.
`rsa1`	Specify the SSHv1 public key of the server to be added to the know host database.
<1-65535>	Specify a key identifier when removing a key using the no parameter.

Default If no cryptography algorithm is specified, then rsa is used as the default cryptography algorithm.

Mode Privilege Exec

Usage This command adds a public key of the specified SSH server to the known host database on the switch. The key is retrieved from the server. The remote SSH server is verified by using this public key. The user is requested to check the key is correct before adding it to the database.

If the remote server's host key is changed, or if the device does not have the public key of the remote server, then SSH clients will inform the user that the public key of the server is altered or unknown.

Examples

To add the RSA host key of the remote SSH host IPv4 address `192.0.2.11` to the known host database, use the command:

```
awplus# crypto key pubkey-chain knownhosts 192.0.2.11
```

To delete the second entry in the known host database, use the command:

```
awplus# no crypto key pubkey-chain knownhosts 2
```

To add the RSA host key of the remote SSH host IPv4 address `192.0.2.11` in VRF `red` to the known host database, use the command:

```
awplus# crypto key pubkey-chain knownhosts vrf red 192.0.2.11
```

To delete the second entry in the known host database in VRF `red`, use the command:

```
awplus# no crypto key pubkey-chain knownhosts vrf red 2
```

Validation Commands

show crypto key pubkey-chain knownhosts

crypto key pubkey-chain userkey

This command adds a public key for an SSH user on the SSH server. This allows the SSH server to support public key authentication for the SSH user. When configured, the SSH user can access the SSH server without providing a password from the remote host.

The no variant of this command removes a public key for the specified SSH user that has been added to the public key chain. When a SSH user's public key is removed, the SSH user can no longer login using public key authentication.

Syntax

```
crypto key pubkey-chain userkey <username> [<filename>]
no crypto key pubkey-chain userkey <username> <1-65535>
```

Parameters	Description
<username>	Name of the user that the SSH server associates the key with. The username must begin with a letter. Valid characters are all numbers, letters, and the underscore, hyphen and full stop symbols. Default: no default
<filename>	Filename of a key saved in flash. Valid characters are any printable character. You can add a key as a hexadecimal string directly into the terminal if you do not specify a filename.
<1-65535>	The key ID number of the user's key. Specify the key ID to delete a key.

Mode Global Configuration

Usage You should import the public key file from the client node. The device can read the data from a file on the flash or user terminal.

Or you can add a key as text into the terminal. To add a key as text into the terminal, first enter the command crypto key pubkey-chain userkey <*username*>, and hit [Enter]. Enter the key as text. Note that the key you enter as text must be a valid SSH RSA key, not random ASCII text. Use [Ctrl]+D after entering it to save the text and re-enter the normal command line mode.

Note you can generate a valid SSH RSA key on the switch first using the crypto key generate host rsa command. View the SSH RSA key generated on the switch using the show crypto hostkey rsa command. Copy and paste the displayed SSH RSA key after entering the crypto key pubkey-chain userkey <*username*> command. Use [Ctrl]+D after entering it to save it.

Examples To generate a valid SSH RSA key on the switch and add the key, use the following commands:

```
awplus# configure terminal

awplus(config)# crypto key generate host rsa

awplus(config)# exit

awplus# show crypto key hostkey rsa

control-D

awplus(config)#
```

To add a public key for the user `graydon` from the file `key.pub`, use the commands:

```
awplus# configure terminal

awplus(config)# crypto key pubkey-chain userkey graydon key.pub
```

To add a public key for the user `tamara` from the terminal, use the commands:

```
awplus# configure terminal

awplus(config)# crypto key pubkey-chain userkey tamara
```

and enter the key. Use Ctrl+D to finish.

To remove the first key entry from the public key chain of the user `john`, use the commands:

```
awplus# configure terminal

awplus(config)# no crypto key pubkey-chain userkey john 1
```

Related Commands show crypto key pubkey-chain userkey

debug ssh client

This command enables the SSH client debugging facility. When enabled, any SSH, SCP and SFTP client sessions send diagnostic messages to the login terminal.

The no variant of this command disables the SSH client debugging facility. This stops the SSH client from generating diagnostic debugging message.

Syntax

```
debug ssh client [brief|full]
no debug ssh client
```

Parameter	Description
`brief`	Enables brief debug mode.
`full`	Enables full debug mode.

Default SSH client debugging is disabled by default.

Mode Privileged Exec and Global Configuration

Examples To start SSH client debugging, use the command:

```
awplus# debug ssh client
```

To start SSH client debugging with extended output, use the command:

```
awplus# debug ssh client full
```

To disable SSH client debugging, use the command:

```
awplus# no debug ssh client
```

Related Commands

debug ssh server
show ssh client
undebug ssh client

debug ssh server

This command enables the SSH server debugging facility. When enabled, the SSH server sends diagnostic messages to the system log. To display the debugging messages on the terminal, use the terminal monitor command.

The no variant of this command disables the SSH server debugging facility. This stops the SSH server from generating diagnostic debugging messages.

Syntax

```
debug ssh server [brief|full]
no debug ssh server
```

Parameter	Description
`brief`	Enables brief debug mode.
`full`	Enables full debug mode.

Default SSH server debugging is disabled by default.

Mode Privileged Exec and Global Configuration

Examples To start SSH server debugging, use the command:

```
awplus# debug ssh server
```

To start SSH server debugging with extended output, use the command:

```
awplus# debug ssh server full
```

To disable SSH server debugging, use the command:

```
awplus# no debug ssh server
```

Related Commands

debug ssh client
show ssh server
undebug ssh server

service ssh

This command enables the Secure Shell server on the device. Once enabled, connections coming from SSH clients are accepted.

SSH server needs a host key before it starts. If an SSHv2 host key does not exist, then this command fails. If SSHv1 is enabled but a host key for SSHv1 does not exist, then SSH service is unavailable for version 1.

The no variant of this command disables the Secure Shell server. When the Secure Shell server is disabled, connections from SSH, SCP, and SFTP clients are not accepted. This command does not affect existing SSH sessions. To terminate existing sessions, use the clear ssh command.

Syntax

```
service ssh [ip|ipv6]
no service ssh [ip|ipv6]
```

Default The Secure Shell server is disabled by default. Both IPv4 and IPv6 Secure Shell server are enabled when you issue service ssh without specifying the optional ip or ipv6 parameters.

Mode Global Configuration

Examples To enable both the IPv4 and the IPv6 Secure Shell server, use the commands:

```
awplus# configure terminal
awplus(config)# service ssh
```

To enable the IPv4 Secure Shell server only, use the commands:

```
awplus# configure terminal
awplus(config)# service ssh ip
```

To enable the IPv6 Secure Shell server only, use the commands:

```
awplus# configure terminal
awplus(config)# service ssh ipv6
```

To disable both the IPv4 and the IPv6 Secure Shell server, use the commands:

```
awplus# configure terminal
awplus(config)# no service ssh
```

To disable the IPv4 Secure Shell server only, use the commands:

```
awplus# configure terminal
awplus(config)# no service ssh ip
```

To disable the IPv6 Secure Shell server only, use the commands:

```
awplus# configure terminal
awplus(config)# no service ssh ipv6
```

crypto key generate hostkey
show running-config ssh
show ssh server
ssh server allow-users
ssh server deny-users

show banner login

This command displays the banner message configured on the device. The banner message is displayed to the remote user before user authentication starts.

Syntax

```
show banner login
```

Mode

User Exec, Privileged Exec, Global Configuration, Interface Configuration, Line Configuration

Example

To display the current login banner message, use the command:

```
awplus# show banner login
```

Related Commands

banner login (SSH)

show crypto key hostkey

This command displays the SSH host keys generated by RSA and DSA algorithm.

A host key pair (public and private keys) is needed to enable SSH server. The private key remains on the device secretly. The public key is copied to SSH clients to identify the server

Syntax `show crypto key hostkey [dsa|rsa|rsa1]`

Parameter	Description
`dsa`	Displays the DSA algorithm public key.
`rsa`	Displays the RSA algorithm public key for SSH version 2 connections.
`rsa1`	Displays the RSA algorithm public key for SSH version 1 connections.

Mode User Exec, Privileged Exec and Global Configuration

Output Figure 76-1: Example output from the **show crypto key hostkey** command

```
Type Bits   Fingerprint
-------------------------------------------------------------
rsa  2058   4e:7d:1d:00:75:79:c5:cb:c8:58:2e:f9:29:9c:1f:48
dsa  1024   fa:72:3d:78:35:14:cb:9a:1d:ca:1c:83:2c:7d:08:43
rsa1 1024   e2:1c:c8:8b:d8:6e:19:c8:f4:ec:00:a2:71:4e:85:8b
```

Table 76-1: Parameters in output of the **show crypto key hostkey** command

Parameter	Description
`Type`	Algorithm used to generate the key.
`Bits`	Length in bits of the key.
`Fingerprint`	Checksum value for the public key.

Examples To show the public keys generated on the device for SSH server, use the command:

```
awplus# show crypto key hostkey
```

To display the RSA public key of the SSH server, use the command:

```
awplus# show crypto key hostkey rsa
```

Related Commands crypto key destroy hostkey
crypto key generate hostkey

show crypto key pubkey-chain knownhosts

This command displays the list of public keys maintained in the known host database on the device.

Syntax

```
show crypto key pubkey-chain knownhosts [vrf <vrf-name>|global]
    [<1-65535>]
```

Parameter	Description
`global`	When VRF-Lite is configured, apply the command to the global routing and forwarding table.
`vrf`	Apply the command to the specified VRF instance.
<vrf-name>	The name of the VRF instance.
<1-65535>	Key identifier for a specific key. Displays the public key of the entry if specified.

Default Display all keys.

Mode User Exec, Privileged Exec and Global Configuration

Usage When VRF-Lite is configured:

- If vrf is specified, this command displays the known host database from the specified VRF instance.
- If global is specified, this command displays the known host database from the global routing environment.
- If neither vrf nor global is specified, this command displays the known host database from the global routing environment and each configured VRF.

For more information about VRF see, Chapter 45, VRF-Lite Introduction and Configuration and Chapter 46, VRF-Lite Commands.

Output Figure 76-2: Example output from the **show crypto key public-chain knownhosts** command

```
No     Hostname         Type Fingerprint
-------------------------------------------------------------------
1      172.16.23.1      rsa  c8:33:b1:fe:6f:d3:8c:81:4e:f7:2a:aa:a5:be:df:18
2      172.16.23.10     rsa  c4:79:86:65:ee:a0:1d:a5:6a:e8:fd:1d:d3:4e:37:bd
3      5ffe:1053:ac21:ff00:0101:bcdf:ffff:0001
                        rsa1 af:4e:b4:a2:26:24:6d:65:20:32:d9:6f:32:06:ba:57
```

Table 76-2: Parameters in the output of the **show crypto key public-chain knownhosts** command

Parameter	Description
`No`	Number ID of the key.
`Hostname`	Host name of the known SSH server.
`Type`	The algorithm used to generate the key.
`Fingerprint`	Checksum value for the public key.

Examples To display public keys of known SSH servers, use the command:

```
awplus# show crypto key pubkey-chain knownhosts
```

To display the key data of the first entry in the known host data, use the command:

```
awplus# show crypto key pubkey-chain knownhosts 1
```

Related Commands crypto key pubkey-chain knownhosts

show crypto key pubkey-chain userkey

This command displays the public keys registered with the SSH server for SSH users. These keys allow remote users to access the device using public key authentication. By using public key authentication, users can access the SSH server without providing password.

Syntax `show crypto key pubkey-chain userkey <username> [<1-65535>]`

Parameter	Description
<username>	User name of the remote SSH user whose keys you wish to display. The username must begin with a letter. Valid characters are all numbers, letters, and the underscore, hyphen and full stop symbols.
<1-65535>	Key identifier for a specific key.

Default Display all keys.

Mode User Exec, Privileged Exec and Global Configuration

Output Figure 76-3: Example output from the **show crypto key public-chain userkey** command

```
No Type Bits Fingerprint
-------------------------------------------------------------
1  dsa  1024 2b:cc:df:a8:f8:2e:8f:a4:a5:4f:32:ea:67:29:78:fd
2  rsa  2048 6a:ba:22:84:c1:26:42:57:2c:d7:85:c8:06:32:49:0e
```

Table 76-3: Parameters in the output of the **show crypto key userkey** command

Parameter	Description
`No`	Number ID of the key.
`Type`	The algorithm used to generate the key.
`Bits`	Length in bits of the key.
`Fingerprint`	Checksum value for the key.

To display the public keys for the user `manager` that are registered with the SSH server, use the command:

```
awplus# show crypto key pubkey-chain userkey manager
```

Related Commands crypto key pubkey-chain userkey

show crypto key userkey

This command displays the public keys created on this device for the specified SSH user.

Syntax `show crypto key userkey <username> [dsa|rsa|rsa1]`

Parameter	Description
`<username>`	User name of the local SSH user whose keys you wish to display. The username must begin with a letter. Valid characters are all numbers, letters, and the underscore, hyphen and full stop symbols.
`dsa`	Displays the DSA public key.
`rsa`	Displays the RSA public key used for SSH version 2 connections.
`rsa1`	Displays the RSA key used for SSH version 1 connections.

Mode User Exec, Privileged Exec and Global Configuration

Output Figure 76-4: Example output from the **show crypto key userkey** command

```
Type Bits   Fingerprint
-------------------------------------------------------------
rsa  2048   e8:d6:1b:c0:f4:b6:e6:7d:02:2e:a9:d4:a1:ca:3b:11
rsa1 1024   12:25:60:95:64:08:8e:a1:8c:3c:45:1b:44:b9:33:9b
```

Table 76-4: Parameters in the output of the **show crypto key userkey** command

Parameter	Description
`Type`	The algorithm used to generate the key.
`Bits`	Length in bits of the key.
`Fingerprint`	Checksum value for the key.

Examples To show the public key generated for the user, use the command:

```
awplus# show crypto key userkey manager
```

To store the RSA public key generated for the user manager to the file "user.pub", use the command:

```
awplus# show crypto key userkey manager rsa > manager-rsa.pub
```

Related Commands crypto key generate userkey

show running-config ssh

This command displays the current running configuration of Secure Shell (SSH).

Syntax `show running-config ssh`

Mode Privileged Exec and Global Configuration

Output Figure 76-5: Example output from the **show running-config ssh** command

```
!
ssh server session-timeout 600
ssh server login-timeout 30
ssh server allow-users manager 192.168.1.*
ssh server allow-users john
ssh server deny-user john*.a-company.com
ssh server
```

Table 76-5: Parameters in the output of the **show running-config ssh** command

Parameter	Description
`ssh server`	SSH server is enabled.
`ssh server v2`	SSH server is enabled and only support SSHv2.
`ssh server <port>`	SSH server is enabled and listening on the specified TCP port.
`no ssh server scp`	SCP service is disabled.
`no ssh server sftp`	SFTP service is disabled.
`ssh server session-timeout`	Configure the server session timeout.
`ssh server login-timeout`	Configure the server login timeout.
`ssh server max-startups`	Configure the maximum number of concurrent sessions waiting authentication.
`no ssh server authentication password`	Password authentication is disabled.
`no ssh server authentication publickey`	Public key authentication is disabled.
`ssh server allow-users`	Add the user (and hostname) to the allow list.
`ssh server deny-users`	Add the user (and hostname) to the deny list.

Example To display the current configuration of SSH, use the command:

```
awplus# show running-config ssh
```

Related Commands service ssh
show ssh server

show ssh

This command displays the active SSH sessions on the device, both incoming and outgoing.

Syntax `show ssh`

Mode User Exec, Privileged Exec and Global Configuration

Output Figure 76-6: Example output from the **show ssh** command

```
Secure Shell Sessions:
ID  Type Mode   Peer Host    Username   State       Filename
---------------------------------------------------------------
414 ssh  server 172.16.23.1  root       open
456 ssh  client 172.16.23.10 manager    user-auth
459 scp  client 172.16.23.12 root       download    550dev_.awd
463 ssh  client 5ffe:33fe:5632:ffbb:bc35:ddee:0101:ac51
                             manager    user-auth
```

Table 76-6: Parameters in the output of the **show ssh** command

Parameter	Description	
ID	Unique identifier for each SSH session.	
Type	Session type; either SSH, SCP, or SFTP.	
Mode	Whether the device is acting as an SSH client (client) or SSH server (server) for the specified session.	
Peer Host	The hostname or IP address of the remote server or client.	
Username	Login user name of the server.	
State	The current state of the SSH session. One of:	
	connecting	The device is looking for a remote server.
	connected	The device is connected to the remote server.
	accepted	The device has accepted a new session.
	host-auth	host-to-host authentication is in progress.
	user-auth	User authentication is in progress.
	authenticated	User authentication is complete.
	open	The session is in progress.
	download	The user is downloading a file from the device.
	upload	The user is uploading a file from the device.
	closing	The user is terminating the session.
	closed	The session is closed.
Filename	Local filename of the file that the user is downloading or uploading.	

Example To display the current SSH sessions on the device, use the command:

```
awplus# show ssh
```

Related Commands clear ssh

show ssh client

This command displays the current configuration of the Secure Shell client.

Syntax `show ssh client`

Mode User Exec, Privileged Exec and Global Configuration

Output Figure 76-7: Example output from the **show ssh client** command

```
Secure Shell Client Configuration
-----------------------------------------------------------------
Port                                : 22
Version                             : 2,1
Connect Timeout                     : 30 seconds
Session Timeout                     : 0 (off)
Debug                               : NONE
```

Table 76-7: Parameters in the output of the **show ssh client** command

Parameter	Description
`Port`	SSH server TCP port where the SSH client connects to. The default is port 22.
`Version`	SSH server version; either "1", "2" or "2,1".
`Connect Timeout`	Time in seconds that the SSH client waits for an SSH session to establish. If the value is 0, the connection is terminated when it reaches the TCP timeout.
`Debug`	Whether debugging is active on the client.

Example To display the current configuration for SSH clients on the login shell, use the command:

```
awplus# show ssh client
```

Related Commands show ssh server

show ssh server

This command displays the current configuration of the Secure Shell server.

Note that changes to the SSH configuration affects only new SSH sessions coming from remote hosts, and does not affect existing sessions.

Syntax `show ssh server`

Mode User Exec, Privileged Exec and Global Configuration

Output Figure 76-8: Example output from the **show ssh server** command

```
Secure Shell Server Configuration
-----------------------------------------------------------------
SSH Server                          : Enabled
Port                                : 22
Version                             : 2
Services                            : scp, sftp
User Authentication                 : publickey, password
Idle Timeout                        : 60 seconds
Maximum Startups                    : 10
Debug                               : NONE
```

Table 76-8: Parameters in the output of the **show ssh server** command

Parameter	Description
`SSH Server`	Whether the Secure Shell server is enabled or disabled.
`Port`	TCP port where the Secure Shell server listens for connections. The default is port 22.
`Version`	SSH server version; either "1", "2" or "2,1".
`Services`	List of the available Secure Shell service; one or more of SHELL, SCP or SFTP.
`Authentication`	List of available authentication methods.
`Login Timeout`	Time (in seconds) that the SSH server will wait the SSH session to establish. If the value is 0, the client login will be terminated when TCP timeout reaches.
`Idle Timeout`	Time (in seconds) that the SSH server will wait to receive data from the SSH client. The server disconnects if this timer limit is reached. If set at 0, the idle timer remains off.
`Maximum Startups`	The maximum number of concurrent connections that are waiting authentication. The default is 10.
`Debug`	Whether debugging is active on the server.

Example To display the current configuration of the Secure Shell server, use the command:

```
awplus# show ssh server
```

Related Commands show ssh
show ssh client

show ssh server allow-users

This command displays the user entries in the allow list of the SSH server.

Syntax `show ssh server allow-users`

Mode User Exec, Privileged Exec and Global Configuration

Output Figure 76-9: Example output from the **show ssh server allow-users** command

```
Username          Remote Hostname (pattern)
----------------- --------------------------------
awplus            192.168.*
john
manager           *.alliedtelesis.com
```

Table 76-9: Parameters in the output of the **show ssh server allow-users** command

Parameter	Description
`Username`	User name that is allowed to access the SSH server.
`Remote Hostname (pattern)`	IP address or hostname pattern of the remote client. The user is allowed requests from a host that matches this pattern. If no hostname is specified, the user is allowed from all hosts.

Example To display the user entries in the allow list of the SSH server, use the command:

```
awplus# show ssh server allow-users
```

Related Commands ssh server allow-users
ssh server deny-users

show ssh server deny-users

This command displays the user entries in the deny list of the SSH server. The user in the deny list is rejected to access the SSH server. If a user is not included in the access list of the SSH server, the user is also rejected.

Syntax `show ssh server deny-users`

Mode User Exec, Privileged Exec and Global Configuration

Output Figure 76-10: Example output from the **show ssh server deny-user** command

```
Username          Remote Hostname (pattern)
----------------- --------------------------------
john              *.b-company.com
manager           192.168.2.*
```

Table 76-10: Parameters in the output of the **show ssh server deny-user** command

Parameter	Description
`Username`	The user that this rule applies to.
`Remote Hostname (pattern)`	IP address or hostname pattern of the remote client. The user is denied requests from a host that matches this pattern. If no hostname is specified, the user is denied from all hosts.

Example To display the user entries in the deny list of the SSH server, use the command:

```
awplus# show ssh server deny-users
```

Related Commands ssh server allow-users
ssh server deny-users

ssh

This command initiates a Secure Shell connection to a remote SSH server.

If the server requests a password for the user login, the user needs to type in the correct password on "Password:" prompt.

SSH client identifies the remote SSH server by it's public key registered on the client device. If the server identification is changed, server verification fails. If the public key of the server has been changed, it is required that the public key of the server should be explicitly added to the known host database.

Note Note that any hostname specified with ssh cannot begin with a hyphen (-) character.

Syntax

```
ssh [vrf <vrf-name>] [ip|ipv6][{[user <username>]|[port <1-65535>]|
   [version {1|2]}}] <hostname> [<line>]
```

Parameter	Description	
`vrf`	Apply the command to the specified VRF instance.	
<vrf-name>	The name of the VRF instance.	
`ip`	Specify IPv4 SSH.	
`ipv6`	Specify IPv6 SSH.	
`user`	Login user. If user is specified, the username is used for login to the remote SSH server when user authentication is required. Otherwise the current user name is used.	
	<username>	User name to login on the remote server.
`port`	SSH server port. If port is specified, the SSH client connects to the remote SSH server with the specified TCP port. Other- wise, the client port configured by "ssh client" command or the default TCP port (22) is used.	
	<1-65535>	TCP port.
`version`	SSH client version. If version is specified, the SSH client supports only the specified SSH version. By default, SSH client uses SSHv2 first. If the server does not support SSHv2, it will try SSHv1. The default version can be configured by "ssh client" command.	
	`1`	Use SSH version 1.
	`2`	Use SSH version 2.

Parameter(cont.)	Description(cont.)	
<hostname>	IPv4/IPv6 address or hostname of a remote server in the format `a.b.c.d` for an IPv4 address, or in the format `x:x::x:x` for an IPv6 address corresponding to the ip or ipv6 optional keywords used. Note that any hostname specified with ssh cannot begin with a hyphen (-) character.	
	<line>	Command to execute on the remote server. If a command is specified, the command is executed on the remote SSH server and the session is disconnected when the remote command finishes.

Mode User Exec and Privileged Exec

Examples To login to the remote SSH server at 192.0.2.5, use the command:

```
awplus# ssh ip 192.0.2.5
```

To login to the remote SSH server at 192.0.2.5 as user manager, use the command:

```
awplus# ssh ip user manager 192.0.2.5
```

To login to the remote SSH server at 192.0.2.5 that is listening TCP port 2000, use the command:

```
awplus# ssh port 2000 192.0.2.5
```

To login to the remote SSH server with example_host using IPv6 session, use the command:

```
awplus# ssh ipv6 example_host
```

To run the cmd command on the remote SSH server at 192.0.2.5, use the command:

```
awplus# ssh ip 192.0.2.5 cmd
```

To login to the remote SSH server at 192.168.1.1 on VRF `red`, use the command:

```
awplus# ssh vrf red 192.168.1.1
```

Related Commands
crypto key generate userkey
crypto key pubkey-chain knownhosts
debug ssh client
ssh client

ssh client

This command modifies the default configuration parameters of the Secure Shell (SSH) client. The configuration is used for any SSH client on the device to connect to remote SSH servers. Any parameters specified on SSH client explicitly override the default configuration parameters.

The change affects the current user shell only. When the user exits the login session, the configuration does not persist. This command does not affect existing SSH sessions.

The no variant of this command resets configuration parameters of the Secure Shell (SSH) client changed by the ssh client command, and restores the defaults.

This command does not affect the existing SSH sessions.

Syntax

```
ssh client {port <1-65535>|version {1|2}|session-timeout <0-3600>|
   connect-timeout <1-600>}

no ssh client {port|version|session-timeout|connect-timeout}
```

Parameter	Description
`port`	The default TCP port of the remote SSH server. If an SSH client specifies an explicit port of the server, it overrides the default TCP port. Default: 22
	<1-65535> TCP port number.
`version`	The SSH version used by the client for SSH sessions. The SSH client supports both version 2 and version 1 Default: version 2 Note: SSH version 2 is the default SSH version. SSH client supports SSH version 1 if SSH version 2 is not configured using a ssh version command.
	`1` SSH clients on the device supports SSH version 1 only.
	`2` SSH clients on the device supports SSH version 2 only
`session-timeout`	The global session timeout for SSH sessions. If the session timer lapses since the last time an SSH client received data from the remote server, the session is terminated. If the value is 0, then the client does not terminate the session. Instead, the connection is terminated when it reaches the TCP timeout. Default: 0 (session timer remains off)
	<0-3600> Timeout in seconds.
`connect-timeout`	The maximum time period that an SSH session can take to become established. The SSH client terminates the SSH session if this timeout expires and the session is still not established. Default: 30
	<1-600> Timeout in seconds.

Mode Privileged Exec

Examples

To configure the default TCP port for SSH clients to 2200, and the session timer to 10 minutes, use the command:

```
awplus# ssh client port 2200 session-timeout 600
```

To configure the connect timeout of SSH client to 10 seconds, use the command:

```
awplus# ssh client connect-timeout 10
```

To restore the connect timeout to its default, use the command:

```
awplus# no ssh client connect-timeout
```

Related Commands

show ssh client
ssh

ssh server

This command modifies the configuration of the SSH server. Changing these parameters affects new SSH sessions connecting to the device.

The no variant of this command restores the configuration of a specified parameter to its default. The change affects the SSH server immediately if the server is running. Otherwise, the configuration is used when the server starts.

To enable the SSH server, use the service ssh command.

Syntax

```
ssh server {[v1v2|v2only]|<1-65535>}
ssh server {[session-timeout <0-3600>] [login-timeout <1-600>]
    [max-startups <1-128>]}
no ssh server {[session-timeout] [login-timeout] [max-startups]}
```

Parameter	Description
v1v2	Supports both SSHv2 and SSHv1client connections. Default: v1v2
v2only	Supports SSHv2 client connections only.
<1-65535>	The TCP port number that the server listens to for incoming SSH sessions. Default: 22
session-timeout	There is a maximum time period that the server waits before deciding that a session is inactive and should be terminated. The server considers the session inactive when it has not received any data from the client, and when the client does not respond to keep alive messages. Default: 0 (session timer remains off).
	<0-3600> Timeout in seconds.
login-timeout	The maximum time period the server waits before disconnecting an unauthenticated client. Default: 60
	<1-600> Timeout in seconds.
max-startups	The maximum number of concurrent unauthenticated connections the server accepts. When the number of SSH connections awaiting authentication reaches the limit, the server drops any additional connections until authentication succeeds or the login timer expires for a connection. Default: 10
	<1-128> Number of sessions.

Mode Global Configuration

Examples To configure the session timer of SSH server to 10 minutes (600 seconds), use the commands:

```
awplus# configure terminal
awplus(config)# ssh server login-timeout 600
```

To configure the login timeout of SSH server to 30 seconds, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server login-timeout 30
```

To limit the number of SSH client connections waiting authentication from SSH server to 3, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server max-startups
```

To set max-startups parameters of SSH server to the default configuration, use the commands:

```
awplus# configure terminal
awplus(config)# no ssh server max-startups
```

To support the Secure Shell server with TCP port 2200, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server 2200
```

To force the Secure Shell server to support SSHv2 only, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server v2only
```

To support both SSHv2 and SSHv1, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server v1v2
```

Related Commands show ssh server
ssh client

ssh server allow-users

This command adds a username pattern to the allow list of the SSH server. If the user of an incoming SSH session matches the pattern, the session is accepted.

When there are no registered users in the server's database of allowed users, the SSH server does not accept SSH sessions even when enabled.

SSH server also maintains the deny list. The server checks the user in the deny list first. If a user is listed in the deny list, then the user access is denied even if the user is listed in the allow list.

The no variant of this command deletes a username pattern from the allow list of the SSH server. To delete an entry from the allow list, the username and hostname pattern should match exactly with the existing entry.

Syntax

```
ssh server allow-users <username-pattern> [<hostname-pattern>]
no ssh server allow-users <username-pattern> [<hostname-pattern>]
```

Parameter	Description
`<username-pattern>`	The username pattern that users can match to. An asterisk acts as a wildcard character that matches any string of characters.
`<hostname-pattern>`	The host name pattern that hosts can match to. If specified, the server allows the user to connect only from hosts matching the pattern. An asterisk acts as a wildcard character that matches any string of characters.

Mode Global Configuration

Example To allow the user `john` to create an SSH session from any host, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server allow-users john
```

To allow the user `john` to create an SSH session from a range of IP address (from 192.168.1.1 to 192.168.1.255), use the commands:

```
awplus# configure terminal
awplus(config)# ssh server allow-users john 192.168.1.*
```

To allow the user `john` to create a SSH session from `a-company.com` domain, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server allow-users john *.a-company.com
```

To delete the existing user entry `john 192.168.1.*` in the allow list, use the commands:

```
awplus# configure terminal
awplus(config)# no ssh server allow-users john 192.168.1.*
```

Related Commands

show running-config ssh
show ssh server allow-users
ssh server deny-users

ssh server authentication

This command enables RSA public-key or password user authentication for SSH Server. Apply the password keyword with the ssh server authentication command to enable password authentication for users. Apply the publickey keyword with the ssh server authentication command to enable RSA public-key authentication for users.

Use the no variant of this command to disable RSA public-key or password user authentication for SSH Server. Apply the password keyword with the no ssh authentication command to disable password authentication for users. Apply the required publickey keyword with the no ssh authentication command to disable RSA public-key authentication for users.

Syntax

```
ssh server authentication {password|publickey}
no ssh server authentication {password|publickey}
```

Parameter	Description
`password`	Specifies user password authentication for SSH server.
`publickey`	Specifies user publickey authentication for SSH server.

Default Both RSA public-key authentication and password authentication are enabled by default.

Mode Global Configuration

Usage For password authentication to authenticate a user, password authentication for a user must be registered in the local user database or on an external RADIUS server, before using the ssh server authentication password command.

For RSA public-key authentication to authenticate a user, a public key must be added for the user, before using the ssh server authentication publickey command.

Example To enable `password` authentication for users connecting through SSH, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server authentication password
```

To enable `publickey` authentication for users connecting through SSH, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server authentication publickey
```

To disable `password` authentication for users connecting through SSH, use the commands:

```
awplus# configure terminal
awplus(config)# no ssh server authentication password
```

To disable `publickey` authentication for users connecting through SSH, use the commands:

```
awplus# configure terminal
awplus(config)# no ssh server authentication publickey
```

Related Commands crypto key pubkey-chain userkey
service ssh
show ssh server

ssh server deny-users

This command adds a username pattern to the deny list of the SSH server. If the user of an incoming SSH session matches the pattern, the session is rejected.

SSH server also maintains the allow list. The server checks the user in the deny list first. If a user is listed in the deny list, then the user access is denied even if the user is listed in the allow list.

If a hostname pattern is specified, the user is denied from the hosts matching the pattern.

The no variant of this command deletes a username pattern from the deny list of the SSH server. To delete an entry from the deny list, the username and hostname pattern should match exactly with the existing entry.

Syntax

```
ssh server deny-users <username-pattern> [<hostname-pattern>]
no ssh server deny-users <username-pattern> [<hostname-pattern>]
```

Parameter	Description
<username-pattern>	The username pattern that users can match to. The username must begin with a letter. Valid characters are all numbers, letters, and the underscore, hyphen, full stop and asterisk symbols. An asterisk acts as a wildcard character that matches any string of characters.
<hostname-pattern>	The host name pattern that hosts can match to. If specified, the server denies the user only when they connect from hosts matching the pattern. An asterisk acts as a wildcard character that matches any string of characters.

Mode Global Configuration

Example To deny the user `john` to access SSH login from any host, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server deny-users john
```

To deny the user john to access SSH login from a range of IP address (from 192.168.2.1 to 192.168.2.255), use the commands:

```
awplus# configure terminal
awplus(config)# ssh server deny-users john 192.168.2.*
```

To deny the user `john` to access SSH login from `b-company.com` domain, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server deny-users john*.b-company.com
```

To delete the existing user entry `john 192.168.2.*` in the deny list, use the commands:

```
awplus# configure terminal
awplus(config)# no ssh server deny-users john 192.168.2.*
```

Related Commands
show running-config ssh
show ssh server deny-users
ssh server allow-users

ssh server resolve-host

This command enables resolving an IP address from a host name using a DNS server for client host authentication.

The no variant of this command disables this feature.

Syntax
```
ssh server resolve-hosts
no ssh server resolve-hosts
```

Default This feature is disabled by default.

Mode Global Configuration

Usage Your device has a DNS Client that is enabled automatically when you add a DNS server to your device. To add a DNS server to the list of servers that the device sends DNS queries to use the ip name-server command on page 25.42.

For information about configuring DNS see "Domain Name System (DNS)" on page 24.8.

Example To resolve a host name using a DNS server, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server resolve-hosts
```

Related Commands
ip name-server
show ssh server
ssh server allow-users
ssh server deny-users

ssh server scp

This command enables the Secure Copy (SCP) service on the SSH server. Once enabled, the server accepts SCP requests from remote clients.

You must enable the SSH server as well as this service before the device accepts SCP connections. The SCP service is enabled by default as soon as the SSH server is enabled.

The no variant of this command disables the SCP service on the SSH server. Once disabled, SCP requests from remote clients are rejected.

Syntax

```
ssh server scp
no ssh server scp
```

Mode Global Configuration

Examples To enable the SCP service, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server scp
```

To disable the SCP service, use the commands:

```
awplus# configure terminal
awplus(config)# no ssh server scp
```

Related Commands show running-config ssh
show ssh server

ssh server sftp

This command enables the Secure FTP (SFTP) service on the SSH server. Once enabled, the server accepts SFTP requests from remote clients.

You must enable the SSH server as well as this service before the device accepts SFTP connections. The SFTP service is enabled by default as soon as the SSH server is enabled. If the SSH server is disabled, SFTP service is unavailable.

The no variant of this command disables SFTP service on the SSH server. Once disabled, SFTP requests from remote clients are rejected.

Syntax

```
ssh server sftp
no ssh server sftp
```

Mode Global Configuration

Examples To enable the SFTP service, use the commands:

```
awplus# configure terminal
awplus(config)# ssh server sftp
```

To disable the SFTP service, use the commands:

```
awplus# configure terminal
awplus(config)# no ssh server sftp
```

Introduction

This chapter provides information about DHCP snooping, support for it on this switch, and how to configure it.

For detailed descriptions of the commands used to configure DHCP snooping, see Chapter 78, DHCP Snooping Commands; for related ACL commands, see Chapter 56, IPv4 Hardware Access Control List (ACL) Commands. For information about Dynamic Host Configuration protocol and how to configure it, see Chapter 85, Dynamic Host Configuration Protocol (DHCP) Introduction and Chapter 86, Dynamic Host Configuration Protocol (DHCP) Commands.

DHCP Snooping

DHCP snooping provides an extra layer of security on the switch via dynamic IP source filtering. DHCP snooping filters out traffic received from unknown, or 'untrusted' ports, and builds and maintains a DHCP snooping database.

Dynamic Host Configuration Protocol (DHCP) dynamically assigns IP addresses to client devices. The use of dynamically assigned addresses requires traceability, so that a service provider can determine which clients own a particular IP address at a certain time.

With DHCP snooping, IP sources are dynamically verified, and filtered accordingly. IP packets that are not sourced from recognized IP addresses can be filtered out. This ensures the required traceability.

With DHCP snooping, an administrator can control port-to-IP connectivity by:

- permitting port access to specified IP addresses only
- permitting port access to DHCP issued IP addresses only
- dictating the number of IP clients on any given port
- passing location information about an IP client to the DHCP server
- permitting only known IP clients to ARP

Ports on the switch are classified as either trusted or untrusted:

- Trusted ports receive only messages from within your network.
- Untrusted ports receive messages from outside your network.

DHCP snooping blocks unauthorized IP traffic from untrusted ports, and prevents it from entering the trusted network. It validates DHCP client packets from untrusted ports and forwards them to trusted ports in the VLAN.

On this switch, DHCP snooping is disabled by default, and can be enabled on per-VLAN basis to operate over switch ports and over static and dynamic (LACP) link aggregators (channel groups).

DHCP Snooping Database

When you enable DHCP snooping, the switch intercepts all DHCP packets it receives, and sends them to the Central Processing Unit (CPU), where they are verified. The DHCP snooping database stores and maintains this information. The database contains entries for:

- current IP address leases dynamically allocated by a DHCP server
- static or dynamic entries added from the command line—typically used to add a DHCP snooping entry for a client that has a preconfigured IP address on an untrusted port

Database backup

The switch periodically saves the dynamic entries in the DHCP snooping database to a hidden file (.dhcp.dsn.gz) in Non-Volatile Storage (NVS), or can be configured to save it to Flash memory or to an SD card. If such a database file exists, it is loaded when the switch starts up with DHCP snooping enabled, or when DHCP snooping is subsequently enabled.

Lease entries

Each entry in the database corresponds to a DHCP IP address lease.

For dynamic entries added automatically by DHCP snooping, each entry contains the following information:

- the IP address that was allocated to that client
- the MAC address of the client device
- the time until expiry
- the VLAN to which the client is attached
- the port to which the client is attached
- the IP address of the DHCP server

For static entries added from the command line, each entry contains the following subset of information:

- the IP address allocated to the client
- the MAC address of the client device (optional)
- the VLAN to which the client is attached
- the port to which the client is attached

Each entry also shows its source: Dynamic or Static.

On this switch, the maximum number of lease entries that can be stored in the DHCP snooping database for each port can be configured—the default is 1.

Expired entries

For dynamic entries, the switch receives expiry information with the client lease information in DHCP packets. Entries expire when the time left to expiry is 0 seconds. Expired entries are automatically deleted from the database. Static entries have no expiry information, and are not checked. All dynamic entries in the database are written to the backup file. Whenever DHCP snooping is enabled, the DHCP snooping database is repopulated from the backup file and any static entries in the start-up configuration file. Any entries present in the backup file that have expired are ignored.

DHCP Option 82

If the switch is at the edge of the network, it can be configured to insert DHCP Option 82 information into client-originated BOOTP/DHCP packets that it is forwarding to a DHCP server. The switch also removes Option 82 information from BOOTP reply packets destined for an untrusted port if the DHCP client hardware is directly attached to a port on the switch.

DHCP servers that are configured to recognize Option 82 may use the information to implement IP address or other parameter assignment policies, based on the network location of the client device.

When Option 82 information for DHCP snooping is enabled, the switch inserts Option 82 information into BOOTP request packets received from an untrusted port. The switch inserts the following Option 82 information:

- Remote ID: this identifies the host. By default, this is the MAC address of the switch (sub-option1).
- Circuit ID: this specifies the switch port and VLAN ID that the client-originated DHCP packet was received on (sub-option2). By default, this is the VLAN ID and the Ifindex (interface number).
- Subscriber ID (optional): this is a string of up to 50 characters that differentiates or groups client ports on the switch (sub-option 6).

Support on this switch

This switch inserts Option 82 (agent option) information into DHCP packets received through untrusted ports, and removes it from DHCP packets transmitted through untrusted ports. This is enabled by default, and can be disabled if required.

You can specify values for the Remote ID and Circuit ID sub-options of the Option 82 field. The Remote ID can be specified as an alphanumeric (ASCII) string, 1 to 63 characters in length. The Circuit ID can be specified as the VLAN ID and port number.

Subscriber IDs can be configured for ports, and if they have been configured, they are inserted in DHCP packets as part of the Option 82 information.

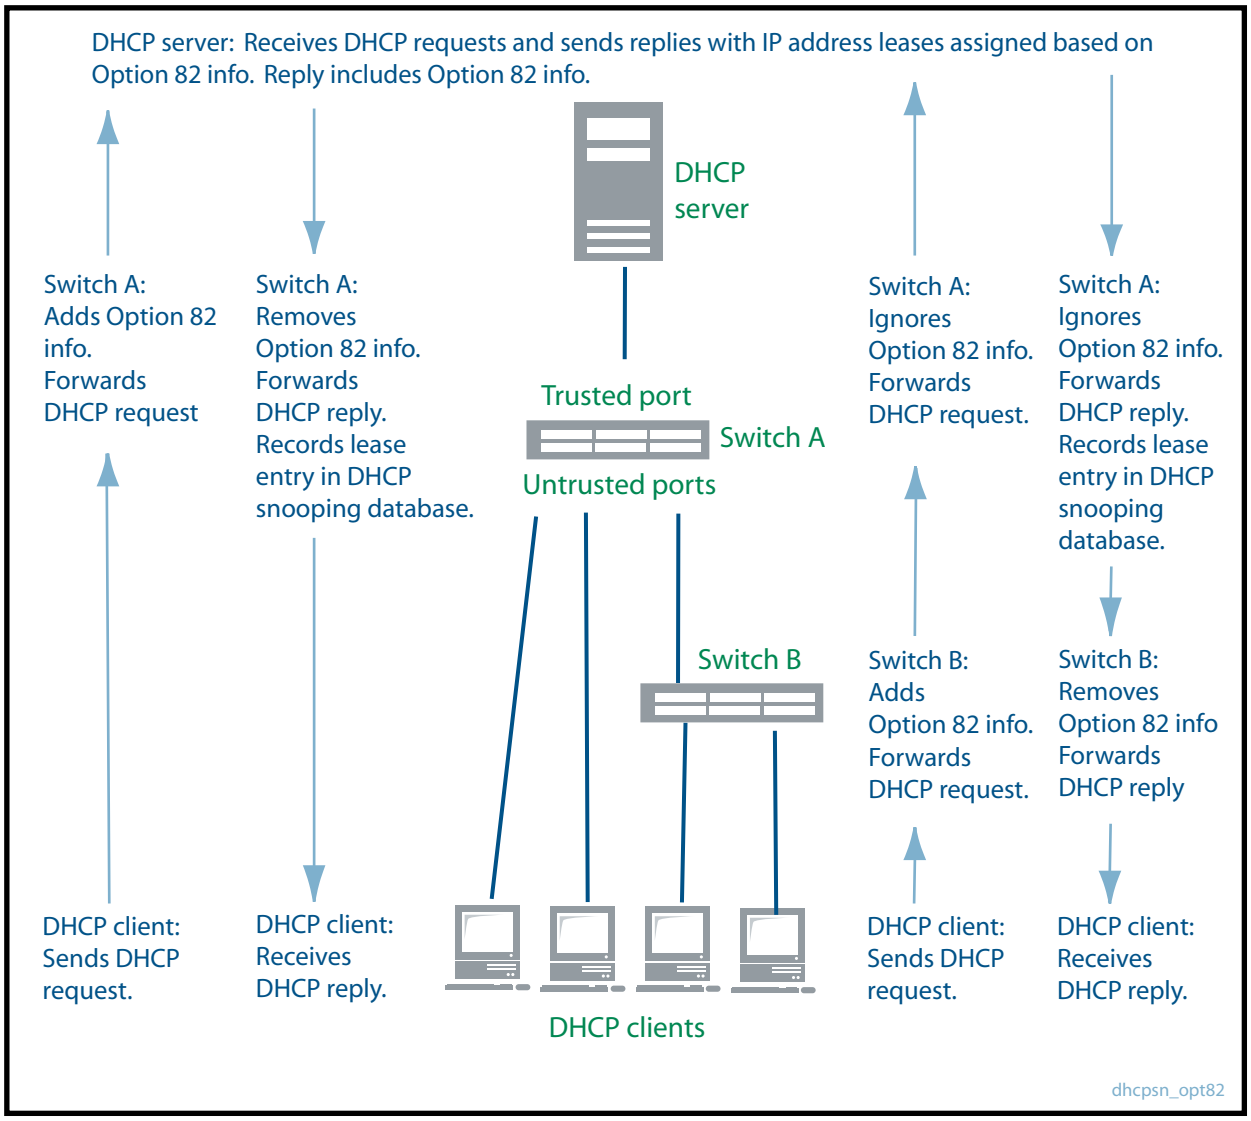
Regardless of whether Option 82 is enabled for DHCP snooping, if the switch receives a BOOTP/DHCP request packet on a trusted port, and the packet contains Option 82 information, it does not update the Option 82 information for the receiver port. By default, if it receives a DHCP request packet containing Option 82 information on an untrusted port, it drops the packet. However, if the switch is connected via untrusted ports to edge switches that insert DHCP Option 82 information into DHCP packets, you may need to allow these DHCP packets through the untrusted ports—the switch can be configured to forward these packets.

Note that the Option 82 agent information inserted by the DHCP snooping differs from the information added by DHCP Relay (see "DHCP Relay Agent Introduction" on page 85.8). The switch cannot be configured to use both the DHCP relay agent option and DHCP snooping.

Operation Figure 77-1 shows DHCP packet flow between DHCP clients and server, where:

- Switch A has DHCP snooping enabled. The DHCP server is connected to a trusted port on Switch A; DHCP clients and Switch B are connected to untrusted ports.
- Switch A is configured to add and remove DHCP Option 82 information (ip dhcp snooping agent-option command on page 78.10).
- Switch A is configured to forward DHCP packets that already contain Option 82 information without changing it (ip dhcp snooping agent-option allow-untrusted command on page 78.11).
- Switch B is Layer 2 switching traffic from downstream DHCP clients, and adds and removes DHCP Option 82 information.

Figure 77-1: DHCP packet flow with DHCP snooping and Option 82 (agent option)



For more information about Option 82, see RFC 3046, DHCP Relay Agent Information Option.

Traffic Filtering with DHCP Snooping

DHCP filtering prevents IP addresses from being falsified or 'spoofed'. This guarantees that customers cannot avoid detection by spoofing IP addresses that are not actually allocated to them. With DHCP filtering, the switch permits packets to enter over a specific port if their source IP address is currently allocated to a client connected to that port.

Support on this switch

On this switch, Access Control Lists (ACLs) based on DHCP snooping can be used with access groups to filter IP packets. For instance, IP traffic on untrusted ports can be limited to packets matching valid DHCP lease information stored in the DHCP snooping database. Quality of Service (QoS) configuration can also be applied to these ACLs.

The DHCP snooping feature is enabled or disabled per VLAN, and several of the related configuration settings are applied per port. If there are multiple VLANs on a port, all the VLANs will be subject to the same per-port settings.

Operation

Table 77-1 on page 77.7 shows the filtering that is applied by DHCP snooping on a switch with the following DHCP filtering configuration for untrusted ports:

- DHCP snooping is enabled on all VLANs (service dhcp-snooping command on page 78.24, ip dhcp snooping command on page 78.9)
- ARP security (arp security command on page 78.2) is enabled on all VLANs
- MAC address verification is enabled on the switch (ip dhcp snooping verify mac-address command on page 78.21; enabled by default), and all DHCP clients are directly connected to the switch.
- Access Control Lists allow IP packets that match the source IP address and MAC address of a valid lease entry in the DHCP snooping database, and deny other IP packets (access-list commands in Chapter 56, IPv4 Hardware Access Control List (ACL) Commands).
- DHCP requests containing Option 82 info are not allowed (ip dhcp snooping agent-option allow-untrusted command on page 78.11 this is disabled by default).
- Log messages and SNMP notifications are enabled for DHCP snooping and ARP security violations (ip dhcp snooping violation command on page 78.22, arp security violation command on page 78.3, snmp-server enable trap command on page 88.17).

Table 77-1: DHCP filtering on the switch

When the switch ...	And ...	Then the switch ...
DHCP packets		
Receives a DHCP BOOTP packet on a trusted port		Forwards the DHCP packet.
	The packet contains a valid IP address lease for a client, and the maximum number of leases for the client port has not been reached.	Adds or updates a lease entry in the DHCP snooping database.
	The maximum number of leases for the client port has been reached.	Drops the DHCP packet, generates a log message for the violation, generates an SNMP notification (trap), and does not add a lease entry to the database.
A lease entry in the DHCP snooping database expires		Removes the expired entry from the database.
Receives a DHCP BOOTP request packet on an untrusted port	The source MAC address and client hardware address match.	
Receives a DHCP BOOTP request packet on an untrusted port	The source MAC address and client hardware address do not match.	Drops the packet, generates a log message for the violation, and sends an SNMP notification (trap).
Receives a DHCP BOOTP request packet on an untrusted port	The packet contains Option 82 info.	Drops the DHCP packet, generates a log message for the violation, and sends an SNMP notification (trap).
Receives a DHCP BOOTP reply packet on an untrusted port		Drops the DHCP packet, generates a log message for the violation, and sends an SNMP notification (trap).
IP packets		
Receives an IP packet on a trusted port		Forwards the IP packet.
Receives an IP packet on an untrusted port	Its source MAC address, IP address, and receiving port match a valid lease entry in the DHCP snooping database.	Forwards the IP packet.
Receives an IP packet on an untrusted port	Its source MAC address, IP address, and receiving port do not match a valid lease entry in the DHCP snooping database.	Drops the packet. Does not generate a log message or an SNMP notification.
ARP packets		
Receives an ARP request on a trusted port		Forwards the ARP packet.
Receives an ARP request on an untrusted port	Its source MAC address, IP address, and receiving port match a valid entry in the DHCP snooping database	Forwards the ARP packet.
Receives an ARP request on an untrusted port	Its source MAC address, IP address, and receiving port do not match an entry in the DHCP snooping database	Drops the packet, generates a log message for the violation, and sends an SNMP notification (trap).

ARP Security

ARP security prevents ARP spoofing. ARP spoofing occurs when devices send fake, or 'spoofed', ARP messages to an Ethernet LAN. This makes it possible for an unauthorized host to claim to be an authorized host. The unauthorized host can then intercept traffic intended for the authorized host, and can access the wider network.

Spoofed ARP messages contain the IP address of an authorized host, with a MAC address which does not match the real MAC address of the host. When ARP security is enabled for DHCP snooping, the switch checks ARP packets sourced from untrusted ports against the entries in the DHCP snooping binding database. If it finds a matching entry, it forwards the ARP packet as normal. If it does not find a matching entry, it drops the ARP packet. This ensures that only trusted clients (with a recognized IP address and MAC address) can generate ARP packets into the network. ARP security is not applied to packets received on trusted ports.

ARP security is disabled by default, and can be enabled on VLANs to ensure that on untrusted ports, only trusted clients (with a recognized IP address and MAC address) can generate ARP packets into the network. ARP security is applied to both dynamic and static DHCP snooping entries. For static DHCP entries without a MAC address defined, ARP security compares only the IP address details.

MAC Address Verification

When MAC address verification is enabled, the switch forwards DHCP packets received on untrusted ports only if the source MAC address and client hardware address match. MAC address verification is enabled by default.

DHCP Snooping Violations

Packets violating DHCP snooping or ARP security checks (if these are enabled) are automatically dropped. The switch can also be configured to send SNMP notifications (atDhcpsnTrap and atArpsecTrap), to generate log messages, or to shut down the link on which the packet was received.

If the switch is configured to send notifications for DHCP snooping or ARP security violations, the rate is limited to one notification per second. If there are any further violations within a second, no notifications are sent for them. After one second, the switch only sends further notifications if the source MAC address and/or the violation reason are different from previous notifications. (If log messages are also generated for ARP security and DHCP snooping violations, you can see a record of all violations in the log, even if notifications were not sent for all of them.)

Interactions with Other Features

DHCP snooping interacts with other switch features as follows:

- Ports in trunk mode

  The DHCP snooping feature is enabled or disabled per VLAN, and several of the related configuration settings are applied to ports. If there are multiple VLANs on a port, all the VLANs will be subject to the same per-port settings.

- DHCP relay

  The switch cannot use DHCP snooping to filter IP traffic from a DHCP relay device.

  DHCP snooping (service dhcp-snooping command on page 78.24) and the DHCP relay agent option (ip dhcp-relay agent-option command on page 86.14) cannot both be enabled on the switch at the same time.

- DHCP snooping can be configured with port provisioning.

- Authentication

  DHCP snooping cannot be enabled on a switch that is configured for web authentication (auth-web enable command on page 65.28), roaming authentication (auth roaming enable command on page 65.17, auth roaming disconnected command on page 65.15), or guest VLAN authentication (auth guest-vlan command on page 65.9), or vice versa.

- Stacking

  If DHCP snooping is enabled in a stack, the DHCP snooping database and its backup file are automatically synchronized across all stack members, so that a new stack master can reinstate this database.

- Link aggregators

  DHCP snooping can operate over switch ports, and over static and dynamic (LACP) link aggregators (channel groups). If a switch port is added to an aggregator, DHCP snooping configuration is applied to the aggregator; configuration of the original switch port is not preserved. If the switch port is then removed from the aggregator, it returns to default DHCP snooping settings.

- Private VLANs

  Private VLANs are not supported for DHCP snooping.

Configuration

This section provides a general configuration procedure for DHCP snooping.

Configure DHCP Snooping

Note that if a port in trunk mode has multiple VLANs attached, then the DHCP snooping configuration settings for the port apply to all the VLANs.

Table 77-2: General configuration procedure for DHCP snooping

Enable DHCP snooping		
1.	`awplus#` `configure terminal`	Enter Global Configuration mode.
2.	`awplus(config)#` `service dhcp-snooping`	Enable DHCP snooping on the switch. Default: disabled
3.	`awplus(config)#` `interface <vid-list>`	Enter Interface Configuration mode for the VLANs to enable DHCP snooping on.
4.	`awplus(config-if)#` `ip dhcp snooping`	Enable DHCP snooping on these VLANs. Default: disabled
5.	`awplus(config-if)#` `exit`	Return to Global Configuration mode.
6.	`awplus(config-if)#` `interface <port-list>`	Enter Interface Configuration mode for ports connected to the trusted network. The port(s) connected to the DHCP server(s) must be configured as trusted ports.
7.	`awplus(config-if)#` `ip dhcp snooping trust`	Set these ports to be trusted ports. Default: untrusted
8.	`awplus(config-if)#` `exit`	Return to Global Configuration mode.
9.	`awplus(config)#` `interface <port-list>`	If you want to allow more than one DHCP lease for any ports, enter Interface Configuration mode for the required ports. The default is likely to be suitable for edge ports; on an aggregation switch, you may need to increase the maximum number of leases for ports connected to other switches and/or for multiple VLANs. Note that you cannot change this setting once DHCP snooping ACLs are attached to these interfaces.

Table 77-2: General configuration procedure for DHCP snooping(cont.)

10.	`awplus(config-if)#` `ip dhcp snooping max-bindings <0-520>`	Change the maximum number of leases for these ports. Default: 1
11.	`awplus(config-if)#` `exit`	Return to Global Configuration mode.
Configure DHCP filtering		
12.	`awplus(config)#` `access-list hardware <name>`	Create a hardware access list, and enter Hardware Access List Configuration mode to configure it. See the access-list hardware (named) command on page 56.19.

13.	`awplus(config-ip-hw-acl)#`
	`[<seqnum>] permit ip dhcpsnooping any`
	`[<seqnum>] deny ip any any`
		Configure the hardware access list to permit traffic with *source IP address* matching valid entries in the DHCP snooping database, and to deny other traffic. (The last filter applied to the ports by any access list must be the filter that denies all other traffic.)
		OR

	`awplus(config-ip-hw-acl)#`
	`[<seqnum>] permit ip dhcpsnooping any mac dhcpsnooping any`
	`[<seqnum>] deny ip any any mac any any`
		Configure the hardware access list to permit traffic with *source IP address and source MAC address* matching valid entries in the DHCP snooping database, and to deny other traffic. (The last filter applied to the ports by any access list must be the filter that denies all other traffic.)
		See the (access-list hardware IP protocol filter) command on page 56.24.

14.	`awplus(config-ip-hw-acl)#` `exit`	Return to Global Configuration mode.
15.	`awplus(config)#` `interface <port-list>`	Enter Interface Configuration mode for the ports to add the DHCP snooping access list to. Typically this would be all untrusted ports.
16.	`awplus(config-if)#` `access-group <name>`	Add the hardware-based access list(s) to these ports. The *name* in this command is the name of the access list specified in Step 12.
17.	`awplus(config-if)#` `exit`	Return to Global Configuration mode.

Table 77-2: General configuration procedure for DHCP snooping(cont.)

Configure ARP security		
18.	`awplus(config)#` `interface <vid-list>`	Enter Interface Configuration mode for the VLANs to enable ARP security on. Default: disabled
19.	`awplus(config-if)#` `arp security`	Enable ARP security on particular VLANs if required. On untrusted ports, ARP security forwards ARP packets that have a source IP address and MAC address matching a dynamic entry in the DHCP snooping database, or an IP address matching a static entry. It drops other ARP packets, and treats them as ARP security violations. Default: disabled
20.	`awplus(config-if)#` `exit`	Return to Global Configuration mode.
Configure DHCP Option 82		
21.	`awplus(config)#` `no ip dhcp snooping agent-option`	If you do not want the switch to insert DHCP Option 82 information into DHCP packets received on untrusted ports, or to remove this information from DHCP packets transmitted on untrusted ports, disable the DHCP Option 82 agent option. Default: enabled if DHCP snooping is enabled.
22.	`awplus(config)#` `ip dhcp snooping agent-option allow-untrusted`	If there are edge switches that add the Option 82 information to DHCP packets, and that are connected to untrusted ports on this switch, you may wish to enable this switch to forward these packets, and the associated DHCP reply packets, without changing the Option 82 information in them. Default: disabled.
23.	`awplus(config)#` `interface <port-list>`	Enter Interface Configuration mode for one or more ports to add a Subscriber ID for.
24.	`awplus(config-if)#` `ip dhcp snooping subscriber-id [<sub-id>]`	Add the Subscriber ID for these ports. The Subscriber ID is included in Option 82 information. Default: no Subscriber ID.
25.	`awplus(config)#` `interface <interface-list>`	Enter Interface Configuration mode for one or more VLANs to add a Circuit ID for.

Table 77-2: General configuration procedure for DHCP snooping(cont.)

26.	`awplus(config-if)#`	
	`ip dhcp snooping agent-option circuit-id vlantriplet`	Specify the Circuit ID for the VLAN or group of VLANs as the VLAN ID and port number. Default: VLAN ID and Ifindex number.
27.	`awplus(config)#`	
	`interface <interface-list>`	Enter Interface Configuration mode for one or more VLANs to add a Remote ID for.
28.	`awplus(config-if)#`	
	`ip dhcp snooping agent-option remote-id <remote-id>`	Specify the Remote ID for the VLAN or group of VLANs as an alphanumeric (ASCII) string, 1 to 63 characters in length. Default: the switch's MAC address.
29.	`awplus(config-if)#`	
	`exit`	Return to Global Configuration mode.
Configure MAC address verification		
30.	`awplus(config)#`	
	`no ip dhcp snooping verify mac-address`	If not required, disable MAC address verification. Default: enabled
Configure the DHCP snooping database		
31.	`awplus(config)#`	
	`ip dhcp snooping database {nvs|flash|card}`	If required, change the location of the file to which the switch writes the dynamic entries from the DHCP snooping database. Default: nvs (non-volatile storage)
32.	`awplus(config)#`	
	`no ip dhcp snooping delete-by-client`	By default, the switch deletes DHCP lease entries from the DHCP snooping database when it receives matching DHCP release messages. Disable these deletions if required, so that lease entries remain in the database until they expire. Default: enabled—entries are deleted when leases are released.
33.	`awplus(config)#`	
	`ip dhcp snooping delete-by-linkdown`	If required, set the switch to delete dynamic entries from the DHCP snooping database when their ports go down. Default: disabled—entries remain if links go down.
34.	`awplus(config)#`	
	`ip source binding <ipaddr> [<macaddr>] vlan <vid> interface <port>`	You can actively add, modify, or remove static entries from the DHCP snooping database.
35.	`awplus#`	
	`ip dhcp snooping binding <ipaddr> [<macaddr>] vlan <vid> interface <port> expiry <expiry-time>`	You can actively add or remove dynamic entries from the DHCP snooping database. These changes affect the current database and backup file, but are not stored in the running configuration.

Table 77-2: General configuration procedure for DHCP snooping(cont.)

Configure violation actions		
36.	`awplus(config)#`	
	`interface <port-list>`	Enter Interface Configuration mode for the ports for which you want to configure actions in response to DHCP snooping or ARP security violations.
37.	`awplus(config-if)#`	
	`ip dhcp snooping violation {log|trap|link-down} ...`	If required, set the switch to generate an SNMP notification (trap), to generate a log message, and/or to block traffic on the port on which a DHCP snooping and/or ARP security violation is detected.
	`arp security violation {log|trap|link-down} ...`	Default: By default, if a packet does not match the DHCP snooping and ARP security restrictions, the packet is dropped, but no other action is taken.
38.	`awplus(config-if)#`	
	`exit`	Return to Global Configuration mode.
39.	`awplus(config)#`	
	`snmp-server enable trap dhcpsnooping`	In order to send SNMP notifications: ■ set the action for violations to trap (Step 37) ■ configure SNMP—see Chapter 88, SNMP Commands ■ set the SNMP server to enable DHCP snooping notifications (by default notifications are disabled on the SNMP server). The port connecting the switch to the SNMP manager should be set as a trusted port (Step 7 on page 77.10).
40.	`awplus(config)#`	
	`exit`	Return to Privileged Exec mode.
Check the configuration		
41.	`awplus#`	
	`show ip dhcp snooping`	Check the DHCP snooping configuration.
	`show ip dhcp snooping interface [<port-list>]`	
	`show ip dhcp snooping acl`	
	`show arp security`	
	`show arp security interface [<port-list>]`	
	`show running-config dhcp`	
Troubleshooting DHCP snooping		
42.	`awplus#`	
	`show ip dhcp snooping binding`	Check all entries in the DHCP snooping database.
43.	`awplus#`	
	`show ip source binding`	Check the static entries in the DHCP snooping database.

Table 77-2: General configuration procedure for DHCP snooping(cont.)

44.	`awplus#`
	`show ip dhcp snooping statistics [detail] [interface <interface-list>]`
	`clear ip dhcp snooping statistics [interface <port-list>]`
		Check DHCP snooping statistics.

45.	`awplus#`
	`show arp security statistics [detail] [interface <port-list>]`
	`clear arp security statistics [interface <port-list>]`
		Check ARP security statistics.

46.	`awplus#`
	`debug ip dhcp snooping {all|acl|db|packet [detail]}`
	`show debugging ip dhcp snooping`
	`debug arp security`
	`show debugging arp security`
		Enable debug output for DHCP snooping and/or ARP security.

47.		If you have not already set the switch to log DHCP snooping and ARP security violations, you can do this for troubleshooting purposes. See Step 37 on page 77.14.
48.	`awplus#` `show log`	Display the contents of the buffered log, including any DHCP snooping log and debug messages. (See also Chapter 10, Logging Commands.)

Disabling DHCP Snooping

If you disable DHCP snooping on the whole switch (no service dhcp-snooping command on page 78.24), all the DHCP snooping configuration is removed, except for the Access Control Lists (ACL). Any ACLs on a port that permit traffic matching DHCP snooping entries and block other traffic, will block all traffic if DHCP snooping is disabled on the port. If you disable DHCP snooping either on the whole switch or on particular VLANs (no ip dhcp snooping command on page 78.9), you must also remove any DHCP snooping ACLs from the ports to maintain connectivity (no access-group command on page 56.4).

Related Features

In addition to configuring DHCP snooping as described in Table 77-2, consider whether you also need to configure the following:

- VLANs—see Chapter 16, VLAN Introduction and Chapter 17, VLAN Commands
- Additional ACL filters—see Chapter 55, Access Control Lists Introduction and Chapter 57, IPv4 Software Access Control List (ACL) Commands
- QoS—see Chapter 60, Quality of Service (QoS) Introduction and Chapter 61, QoS Commands
- SNMP—Chapter 87, SNMP Introduction and Chapter 88, SNMP Commands

Chapter 78: DHCP Snooping Commands

Command List 78.2
arp security 78.2
arp security violation 78.3
clear arp security statistics 78.4
clear ip dhcp snooping binding 78.5
clear ip dhcp snooping statistics 78.6
debug arp security 78.7
debug ip dhcp snooping 78.8
ip dhcp snooping 78.9
ip dhcp snooping agent-option 78.10
ip dhcp snooping agent-option allow-untrusted 78.11
ip dhcp snooping agent-option circuit-id vlantriplet 78.12
ip dhcp snooping agent-option remote-id 78.13
ip dhcp snooping binding 78.14
ip dhcp snooping database 78.15
ip dhcp snooping delete-by-client 78.16
ip dhcp snooping delete-by-linkdown 78.17
ip dhcp snooping max-bindings 78.18
ip dhcp snooping subscriber-id 78.19
ip dhcp snooping trust 78.20
ip dhcp snooping verify mac-address 78.21
ip dhcp snooping violation 78.22
ip source binding 78.23
service dhcp-snooping 78.24
show arp security 78.26
show arp security interface 78.27
show arp security statistics 78.28
show debugging arp security 78.30
show debugging ip dhcp snooping 78.31
show ip dhcp snooping 78.32
show ip dhcp snooping acl 78.33
show ip dhcp snooping agent-option 78.35
show ip dhcp snooping binding 78.37
show ip dhcp snooping interface 78.38
show ip dhcp snooping statistics 78.40
show ip source binding 78.43

Command List

This chapter gives detailed information about the commands used to configure DHCP snooping. For detailed descriptions of related ACL commands, see Chapter 56, IPv4 Hardware Access Control List (ACL) Commands. For more information about DHCP snooping, see Chapter 77, DHCP Snooping Introduction and Configuration.

DHCP snooping can operate on static link aggregators (e.g., sa2) and dynamic link aggregators (e.g. po3) link aggregators, as well as switch ports (e.g., port1.0.2).

arp security

Use this command to enable ARP security on untrusted ports in the VLANs, so that the switch only responds to/forwards ARP packets if they have recognized IP and MAC source addresses.

Use the no variant of this command to disable ARP security on the VLANs.

Syntax

```
arp security
no arp security
```

Default Disabled

Mode Interface Configuration (VLANs)

Usage Enable ARP security to provide protection against ARP spoofing. DHCP snooping must also be enabled on the switch (service dhcp-snooping command on page 78.24), and on the VLANs (ip dhcp snooping command on page 78.9).

Example To enable ARP security on VLANs 2 to 4, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config-if)# arp security
```

Related Commands

arp security violation
show arp security
show arp security interface
show arp security statistics

arp security violation

Use this command to specify an additional action to perform if an ARP security violation is detected on the ports. ARP security must also be enabled (arp security command on page 78.2).

Use the no variant of this command to remove the specified action, or all actions. Traffic violating ARP security will be dropped, but no other action will be taken.

Syntax

```
arp security violation {log|trap|link-down} ...
no arp security violation [log|trap|link-down] ...
```

Parameter	Description
`log`	Generate a log message. To display these messages, use the show log command on page 10.40.
`trap`	Generate an SNMP notification (trap). To send SNMP notifications, SNMP must also be configured, and DHCP snooping notifications must be enabled using the snmp-server enable trap command on page 88.17. Notifications are limited to one per second and to one per source MAC and violation reason. Additional violations within a second of a notification being sent will not result in further notifications. Default: disabled.
`link-down`	Shut down the port that received the packet. Default: disabled.

Default When the switch detects an ARP security violation, it drops the packet. By default, it does not perform any other violation actions.

Mode Interface Configuration (switch ports, static or dynamic aggregated links)

Usage When the switch detects an ARP security violation on an untrusted port in a VLAN that has ARP security enabled, it drops the packet. This command sets the switch to perform additional actions in response to ARP violations.

If a port has been shut down in response to a violation, to bring it back up again after any issues have been resolved, use the no shutdown command on page 11.13.

Example To send SNMP notifications for ARP security violations on ports 1.0.1 to 1.0.8, use the commands:

```
awplus# configure terminal
awplus(config)# snmp-server enable trap dhcpsnooping
awplus(config)# interface port1.0.1-port1.0.8
awplus(config-if)# arp security violation trap
```

Related Commands

arp security
show arp security interface
show arp security statistics
show log
snmp-server enable trap

clear arp security statistics

Use this command to clear ARP security statistics for the specified ports, or for all ports.

Syntax

```
clear arp security statistics [interface <port-list>]
```

Parameter	Description
<port-list>	The ports to clear statistics for. If no ports are specified, statistics are cleared for all ports. The ports may be switch ports, or static or dynamic link aggregators.

Mode

Privileged Exec

Example

To clear statistics for ARP security on interface port1.0.1, use the command:

```
awplus# clear arp security statistics interface port1.0.1
```

Related Commands

arp security violation
show arp security
show arp security statistics

clear ip dhcp snooping binding

Use this command to remove one or more DHCP Snooping dynamic entries from the DHCP Snooping binding database. If no options are specified, all entries are removed from the database.

Caution If you remove entries from the database for current clients, they will lose IP connectivity until they request and receive a new DHCP lease. If you clear all entries, all clients connected to untrusted ports will lose connectivity.

Syntax

```
clear ip dhcp snooping binding [<ipaddr>] [interface <port-list>]
   [vlan <vid-list>]
```

Parameter	Description
<ipaddr>	Remove the entry for this client IP address.
<port-list>	Remove all entries for these ports. The port list may contain switch ports, and static or dynamic link aggregators (channel groups).
<vid-list>	Remove all entries associated with these VLANs.

Mode Privileged Exec

Usage This command removes dynamic entries from the database. Note that dynamic entries can also be deleted by using the no variant of the ip dhcp snooping binding command on page 78.14.

Dynamic entries can individually restored by using the ip dhcp snooping binding command.

To remove static entries, use the no variant of the ip source binding command on page 78.23.

Example To remove a dynamic lease entry from the DHCP snooping database for a client with the IP address 192.168.1.2, use the command:

```
awplus# clear ip dhcp snooping binding 192.168.1.2
```

Related Commands
ip dhcp snooping binding
ip source binding
show ip dhcp snooping binding

clear ip dhcp snooping statistics

Use this command to clear DHCP snooping statistics for the specified ports, or for all ports.

Syntax `clear ip dhcp snooping statistics [interface <port-list>]`

Parameter	Description
<port-list>	The ports to clear statistics for. If no ports are specified, statistics are cleared for all ports. The port list can contain switch ports, or static or dynamic link aggregators.

Mode Privileged Exec

Example To clear statistics for the DHCP snooping on interface port1.0.1, use the command:

```
awplus# clear ip dhcp snooping statistics interface port1.0.1
```

Related Commands
clear arp security statistics
show ip dhcp snooping
show ip dhcp snooping statistics

debug arp security

Use this command to enable ARP security debugging.

Use the no variant of this command to disable debugging for ARP security.

Syntax

```
debug arp security
no debug arp security
```

Default Disabled

Mode Privileged Exec

Example To enable ARP security debugging, use the commands:

```
awplus# debug arp security
```

Related Commands

show debugging arp security
show log
terminal monitor

debug ip dhcp snooping

Use this command to enable the specified types of debugging for DHCP snooping.

Use the no variant of this command to disable the specified types of debugging.

Syntax

```
debug ip dhcp snooping {all|acl|db|packet [detail]}
no debug ip dhcp snooping {all|acl|db|packet [detail]}
```

Parameter	Description
`all`	All DHCP snooping debug.
`acl`	DHCP snooping access list debug.
`db`	DHCP snooping binding database debug.
`packet`	DHCP snooping packet debug. For the no variant of this command, this option also disables detailed packet debug, if it was enabled.
`detail`	Detailed packet debug.

Default Disabled

Mode Privileged Exec

Example To enable access list debugging for DHCP snooping, use the commands:

```
awplus# debug ip dhcp snooping acl
```

Related Commands

debug arp security
show debugging ip dhcp snooping
show log
terminal monitor

ip dhcp snooping

Use this command to enable DHCP snooping on one or more VLANs.

Use the no variant of this command to disable DHCP snooping on the VLANs.

Syntax

```
ip dhcp snooping
no ip dhcp snooping
```

Default DHCP snooping is disabled on VLANs by default.

Mode Interface Configuration (VLANs)

Usage For DHCP snooping to operate on a VLAN, it must:

- be enabled on the particular VLAN by using this command
- be enabled globally on the switch by using the service dhcp-snooping command on page 78.24
- have at least one port connected to a DHCP server configured as a trusted port by using the ip dhcp snooping trust command on page 78.20

Any ACLs on a port that permit traffic matching DHCP snooping entries and block other traffic, will block all traffic if DHCP snooping is disabled on the port. If you disable DHCP snooping on particular VLANs using this command, you must also remove any DHCP snooping ACLs from the ports to maintain connectivity (no access-group command on page 56.4).

Example To enable DHCP snooping on VLANs 2 to 4, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config-if)# ip dhcp snooping
```

To disable DHCP snooping on the switch, use the command:

```
awplus# configure terminal
awplus(config)# interface vlan2-vlan4
awplus(config-if)# no ip dhcp snooping
```

Related Commands

ip dhcp snooping trust
service dhcp-snooping
show ip dhcp snooping

ip dhcp snooping agent-option

Use this command to enable DHCP Option 82 data insertion on the switch. When this is enabled, the switch:

- inserts DHCP Option 82 into DHCP packets that it receives on untrusted ports
- removes DHCP Option 82 from DHCP packets that it sends to untrusted ports.

Use the no variant of this command to disable DHCP Option 82.

Syntax

```
ip dhcp snooping agent-option
no ip dhcp snooping agent-option
```

Default DHCP Option 82 is enabled by default when DHCP snooping is enabled.

Mode Global Configuration

Usage DHCP snooping must also be enabled on the switch (service dhcp-snooping command on page 78.24), and on the VLANs (ip dhcp snooping command on page 78.9).

If a subscriber ID is configured for the port (ip dhcp snooping subscriber-id command on page 78.19), the switch includes this in the DHCP Option 82 information it inserts into DHCP packets received on the port.

Example To disable DHCP Option 82 on the switch, use the commands:

```
awplus# configure terminal
awplus(config)# no ip dhcp snooping agent-option
```

Related Commands

ip dhcp snooping
ip dhcp snooping agent-option allow-untrusted
ip dhcp snooping subscriber-id
service dhcp-snooping
show ip dhcp snooping

ip dhcp snooping agent-option allow-untrusted

Use this command to enable DHCP Option 82 reception on untrusted ports. When this is enabled, the switch accepts incoming DHCP packets that contain DHCP option 82 data on untrusted ports.

Use the no variant of this command to disable DHCP Option 82 reception on untrusted ports.

Syntax

```
ip dhcp snooping agent-option allow-untrusted
no ip dhcp snooping agent-option allow-untrusted
```

Default Disabled

Mode Global Configuration

Usage If the switch is connected via untrusted ports to edge switches that insert DHCP Option 82 data into DHCP packets, you may need to allow these DHCP packets through the untrusted ports, by using this command.

When this is disabled (default), the switch treats incoming DHCP packets on untrusted ports that contain DHCP option 82 data as DHCP snooping violations: it drops them and applies any violation action specified by the ip dhcp snooping violation command on page 78.22. The switch stores statistics for packets dropped; to display these statistics, use the show ip dhcp snooping statistics command on page 78.40.

Example To enable DHCP snooping Option 82 data reception on untrusted ports, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp snooping agent-option allow-untrusted
```

Related Commands

ip dhcp snooping agent-option
ip dhcp snooping violation
show ip dhcp snooping
show ip dhcp snooping statistics

ip dhcp snooping agent-option circuit-id vlantriplet

Use this command to specify the Circuit ID sub-option of the Option 82 field as the VLAN ID and port number. The Circuit ID specifies the switch port and VLAN ID that the client-originated DHCP packet was received on.

Use the no variant of this command to set the Circuit ID to the default, the VLAN ID and Ifindex (interface number).

Syntax

```
ip dhcp snooping agent-option circuit-id vlantriplet
no ip dhcp snooping agent-option circuit-id
```

Default By default, the Circuit ID is the VLAN ID and Ifindex (interface number).

Mode Interface Configuration for a VLAN interface.

Usage The Circuit ID sub-option is included in the DHCP Option 82 field of forwarded client DHCP packets:

- DHCP snooping Option 82 is enabled (ip dhcp snooping agent-option command on page 78.10; enabled by default), and
- DHCP snooping is enabled on the switch (service dhcp-snooping) and on the VLAN to which the port belongs (ip dhcp snooping)

Examples To set the Circuit ID to `vlantriplet` for client DHCP packets received on `vlan1`, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan1
awplus(config-if)# ip dhcp snooping agent-option circuit-id
vlantriplet
```

To return the Circuit ID format to the default for `vlan1`, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan1
awplus(config-if)# no ip dhcp snooping agent-option circuit-id
```

Related Commands

ip dhcp snooping agent-option
ip dhcp snooping agent-option remote-id
show ip dhcp snooping
show ip dhcp snooping agent-option

ip dhcp snooping agent-option remote-id

Use this command to specify the Remote ID sub-option of the Option 82 field. The Remote ID identifies the device that inserted the Option 82 information. If a Remote ID is not specified, the Remote ID sub-option is set to the switch's MAC address.

Use the no variant of this command to set the Remote ID to the default, the switch's MAC address.

Syntax

```
ip dhcp snooping agent-option remote-id <remote-id>
no ip dhcp snooping agent-option remote-id
```

Parameter	Description
<remote-id>	An alphanumeric (ASCII) string, 1 to 63 characters in length. If the Remote ID contains spaces, it must be enclosed in double quotes. Wildcards are not allowed.

Default The Remote ID is set to the switch's MAC address by default.

Mode Interface Configuration for a VLAN interface.

Usage The Remote ID sub-option is included in the DHCP Option 82 field of forwarded client DHCP packets:

- DHCP snooping Option 82 is enabled (ip dhcp snooping agent-option command on page 78.10; enabled by default), and
- DHCP snooping is enabled on the switch (service dhcp-snooping) and on the VLAN to which the port belongs (ip dhcp snooping)

Examples To set the Remote ID to `myid` for client DHCP packets received on `vlan1`, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan1
awplus(config-if)# ip dhcp snooping agent-option remote-id
myid
```

To return the Remote ID format to the default for `vlan1`, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan1
awplus(config-if)# no ip dhcp snooping agent-option remote-id
```

Related Commands

ip dhcp snooping agent-option
ip dhcp snooping agent-option circuit-id vlantriplet
show ip dhcp snooping
show ip dhcp snooping agent-option

ip dhcp snooping binding

Use this command to manually add a dynamic-like entry (with an expiry time) to the DHCP snooping database. Once added to the database, this entry is treated as a dynamic entry, and is stored in the DHCP snooping database backup file. This command is not stored in the switch's running configuration.

Use the no variant of this command to delete a dynamic entry for an IP address from the DHCP snooping database, or to delete all dynamic entries from the database.

Caution If you remove entries from the database for current clients, they will lose IP connectivity until they request and receive a new DHCP lease. If you clear all entries, all clients connected to untrusted ports will lose connectivity.

Syntax

```
ip dhcp snooping binding <ipaddr> [<macaddr>] vlan <vid> interface
   <port> expiry <expiry-time>

no ip dhcp snooping binding [<ipaddr>]
```

Parameter	Description
<ipaddr>	Client's IP address.
<macaddr>	Client's MAC address in HHHH.HHHH.HHHH format.
<vid>	The VLAN ID for the entry, in the range 1 to 4094.
<port>	The port the client is connected to. The port can be a switch port, or a static or dynamic link aggregation (channel group).
<expiry-time>	The expiry time for the entry, in the range 5 to 2147483647 seconds.

Mode Privileged Exec

Usage Note that dynamic entries can also be deleted from the DHCP snooping database by using the clear ip dhcp snooping binding command on page 78.5.

To add or remove static entries from the database, use the ip source binding command on page 78.23.

Example To restore an entry in the DHCP snooping database for a DHCP client with the IP address 192.168.1.2, MAC address 0001.0002.0003, on port1.0.6 of vlan6, and with an expiry time of 1 hour, use the commands:

```
awplus# ip dhcp snooping binding 192.168.1.2 0001.0002.0003
        vlan 6 interface port1.0.6 expiry 3600
```

Related Commands

clear ip dhcp snooping binding
ip source binding
show ip dhcp snooping binding

ip dhcp snooping database

Use this command to set the location of the file to which the dynamic entries in the DHCP snooping database are written. This file provides a backup for the DHCP snooping database.

Use the no variant of this command to set the database location back to the default, nvs.

Syntax

```
ip dhcp snooping database {nvs|flash|card}
no ip dhcp snooping database
```

Parameter	Description
nvs	The switch checks the database and writes the file to non-volatile storage (NVS) on the switch at 2 second intervals if it has changed.
flash	The switch checks the database and writes the file to Flash memory on the switch at 60 second intervals if it has changed.
card	The switch checks the database and writes the file to an SD card installed in the switch at 2 second intervals if it has changed. Note that a current DHCP snooping backup database file is essential to maintain connectivity for DHCP clients after a switch reboot. If you configure the switch to save this file to an SD card, we recommend that you ensure the card is always present.

Default NVS

Mode Global Configuration

Usage In a stack, the backup file is automatically synchronized across all stack members to the location configured. If the backup file is stored on an SD card on the stack master, it is only synchronized across stack members that also have an SD card installed.

If the location of the backup file is changed by using this command, a new file is created in the new location, and the old version of the file remains in the old location. This can be removed if necessary (hidden file: .dhcp.dsn.gz).

Example To set the location of the DHCP snooping database to non-volatile storage on the switch, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp snooping database nvs
```

Related Commands show ip dhcp snooping

ip dhcp snooping delete-by-client

Use this command to set the switch to remove a dynamic entry from the DHCP snooping database when it receives a valid DHCP release message with matching IP address, VLAN ID, and client hardware address on an untrusted port, and to discard release messages that do not match an entry in the database.

Use the no variant of this command to set the switch to forward DHCP release messages received on untrusted ports without removing any entries from the database.

Syntax

```
ip dhcp snooping delete-by-client
no ip dhcp snooping delete-by-client
```

Default Enabled: by default, DHCP lease entries are deleted from the DHCP snooping database when matching DHCP release messages are received.

Mode Global Configuration

Usage DHCP clients send a release message when they no longer wish to use the IP address they have been allocated by a DHCP server. Use this command to enable DHCP snooping to use the information in these messages to remove entries from its database immediately. Use the no variant of this command to ignore these release messages. Lease entries corresponding to ignored DHCP release messages eventually time out when the lease expires.

Example To set the switch to delete DHCP snooping lease entries from the DHCP snooping database when a matching release message is received, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp snooping delete-by-client
```

To set the switch to forward and ignore the content of any DHCP release messages it receives, use the commands:

```
awplus# configure terminal
awplus(config)# no ip dhcp snooping delete-by-client
```

Related Commands show ip dhcp snooping

ip dhcp snooping delete-by-linkdown

Use this command to set the switch to remove a dynamic entry from the DHCP snooping database when its port goes down. If the port is part of an aggregated link, the entries in the database are only deleted if all the ports in the aggregated link are down.

Use the no variant of this command to set the switch not to delete entries when ports go down.

Syntax

```
ip dhcp snooping delete-by-linkdown
no ip dhcp snooping delete-by-linkdown
```

Default Disabled: by default DHCP Snooping bindings are not deleted when an interface goes down.

Mode Global Configuration

Usage If this command is enabled in a stack, and the master goes down and is replaced by a new master, entries in the DHCP snooping database for ports on the master are removed, unless they are part of link aggregators that are still up.

Examples To set the switch to delete DHCP snooping lease entries from the DHCP snooping database when links go down, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp snooping delete-by-linkdown
```

To set the switch *not* to delete DHCP snooping lease entries from the DHCP snooping database when links go down, use the commands:

```
awplus# configure terminal
awplus(config)# no ip dhcp snooping delete-by-linkdown
```

Related Commands show ip dhcp snooping

ip dhcp snooping max-bindings

Use this command to set the maximum number of DHCP lease entries that can be stored in the DHCP snooping database for each of the ports. Once this limit has been reached, no further DHCP lease allocations made to devices on the port are stored in the database.

Use the no variant of this command to reset the maximum to the default, 1.

Syntax

```
ip dhcp snooping max-bindings <0-520>
no ip dhcp snooping max-bindings
```

Parameter	Description
<0-520>	The maximum number of bindings that will be stored for the port in the DHCP snooping binding database. If 0 is specified, no entries will be stored in the database for the port.

Default The default for maximum bindings is 1.

Mode Interface Configuration (port)

Usage The maximum number of leases cannot be changed for a port while there are DHCP snooping Access Control Lists (ACL) associated with the port. Before using this command, remove any DHCP snooping ACLs associated with the ports. To display ACLs used for DHCP snooping, use the show ip dhcp snooping acl command on page 78.33.

In general, the default (1) will work well on an edge port with a single directly connected DHCP client. If the port is on an aggregation switch that is connected to an edge switch with multiple DHCP clients connected through it, then use this command to increase the number of lease entries for the port.

If there are multiple VLANs configured on the port, the limit is shared between all the VLANs on this port. For example, the default only allows one lease to be stored for one VLAN. To allow connectivity for the other VLANs, use this command to increase the number of lease entries for the port.

Example To set the maximum number of bindings to be stored in the DHCP snooping database to 10 per port for ports 1.0.1 to 1.0.8, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1-port1.0.8
awplus(config-if)# ip dhcp snooping max-bindings 10
```

Related Commands

access-group
show ip dhcp snooping acl
show ip dhcp snooping interface

ip dhcp snooping subscriber-id

Use this command to set a Subscriber ID for the ports.

Use the no variant of this command to remove Subscriber IDs from the ports.

Syntax

```
ip dhcp snooping subscriber-id [<sub-id>]
no ip dhcp snooping subscriber-id
```

Parameter	Description
<sub-id>	The Subscriber ID; an alphanumeric (ASCII) string 1 to 50 characters in length. If the Subscriber ID contains spaces, it must be enclosed in double quotes. Wildcards are not allowed.

Default No Subscriber ID.

Mode Interface Configuration (port)

Usage The Subscriber ID sub-option is included in the DHCP Option 82 field of client DHCP packets forwarded from a port if:

- a Subscriber ID is specified for the port using this command, and
- DHCP snooping Option 82 is enabled (ip dhcp snooping agent-option command on page 78.10; enabled by default), and
- DHCP snooping is enabled on the switch (service dhcp-snooping) and on the VLAN to which the port belongs (ip dhcp snooping)

Example To set the Subscriber ID for port 1.0.3 to room_534, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.3
awplus(config-if)# ip dhcp snooping subscriber-id room_534
```

To remove the Subscriber ID from port 1.0.3, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.3
awplus(config-if)# no ip dhcp snooping subscriber-id
```

Related Commands
ip dhcp snooping agent-option
show ip dhcp snooping interface

ip dhcp snooping trust

Use this command to set the ports to be DHCP snooping trusted ports.

Use the no variant of this command to return the ports to their default as untrusted ports.

Syntax

```
ip dhcp snooping trust
no ip dhcp snooping trust
```

Default All ports are untrusted by default.

Mode Interface Configuration (port)

Usage Typically, ports connecting the switch to trusted elements in the network (towards the core) are set as trusted ports, while ports connecting untrusted network elements are set as untrusted. Configure ports connected to DHCP servers as trusted ports.

Example To set switch ports 1.0.1 and 1.0.2 to be trusted ports, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1-port1.0.2
awplus(config-if)# ip dhcp snooping trust
```

Related Commands show ip dhcp snooping interface

ip dhcp snooping verify mac-address

Use this command to verify that the source MAC address and client hardware address match in DHCP packets received on untrusted ports.

Use the no variant of this command to disable MAC address verification.

Syntax

```
ip dhcp snooping verify mac-address
no ip dhcp snooping verify mac-address
```

Default Enabled—source MAC addresses are verified by default.

Mode Global Configuration

Usage When MAC address verification is enabled, the switch treats DHCP packets with source MAC address and client hardware address that do not match as DHCP snooping violations: it drops them and applies any other violation action specified by the ip dhcp snooping violation command on page 78.22. To bring the port back up again after any issues have been resolved, use the no shutdown command on page 11.13.

Example To disable MAC address verification on the switch, use the commands:

```
awplus# configure terminal
awplus(config)# no ip dhcp snooping verify mac-address
```

Related Commands

ip dhcp snooping violation
show ip dhcp snooping
show ip dhcp snooping statistics

ip dhcp snooping violation

Use this command to specify the action the switch will take when it detects a DHCP snooping violation by a DHCP packet on the ports.

Use the no variant of this command to disable the specified violation actions, or all violation actions.

Syntax

```
ip dhcp snooping violation {log|trap|link-down} ...
no ip dhcp snooping violation [{log|trap|link-down} ...]
```

Parameter	Description
`log`	Generate a log message. To display these messages, use the show log command on page 10.40. Default: disabled.
`trap`	Generate an SNMP notification (trap). To send SNMP notifications, SNMP must also be configured, and DHCP snooping notifications must be enabled using the snmp-server enable trap command on page 88.17. Notifications are limited to one per second and to one per source MAC and violation reason. Default: disabled.
`link-down`	Set the port status to link-down. Default: disabled.

Default By default, DHCP packets that violate DHCP snooping are dropped, but no other violation action is taken.

Mode Interface Configuration (port)

Usage If a port has been shut down in response to a violation, to bring it back up again after any issues have been resolved, use the no shutdown command on page 11.13.

IP packets dropped by DHCP snooping filters do not result in other DHCP snooping violation actions.

Example To set the switch to send an SNMP notification and set the link status to link-down if it detects a DHCP snooping violation on switch ports 1.0.1 to 1.0.4, use the commands:

```
awplus# configure terminal
awplus(config)# snmp-server enable trap dhcpsnooping
awplus(config)# interface port1.0.1-port1.0.4
awplus(config-if)# ip dhcp snooping violation trap link-down
```

Related Commands

show ip dhcp snooping interface
show log
snmp-server enable trap

ip source binding

Use this command to add or replace a static entry in the DHCP snooping database.

Use the no variant of this command to delete the specified static entry or all static entries from the database.

Syntax

```
ip source binding <ipaddr> [<macaddr>] vlan <vid> interface <port>
no ip source binding [<ipaddr>]
```

Parameter	Description
<ipaddr>	Client's IP address. If there is already an entry in the DHCP snooping database for this IP address, then this command replaces it with the new entry.
<macaddr>	Client's MAC address in HHHH.HHHH.HHHH format.
<vid>	The VLAN ID associated with the entry.
<port>	The port the client is connected to.

Mode Global Configuration

Usage This command removes static entries from the database.

To remove dynamic entries, use the clear ip dhcp snooping binding command on page 78.5 or the no variant of the ip dhcp snooping binding command on page 78.14.

Example To add a static entry to the DHCP snooping database for a client with the IP address 192.168.1.2, MAC address 0001.0002.0003, on port1.0.6 of vlan6, use the command:

```
awplus# configure terminal
awplus(config)# ip source binding 192.168.1.2 0001.0002.0003
vlan 6 interface port1.0.6
```

To remove the static entry for IP address 192.168.1.2 from the database, use the commands:

```
awplus# configure terminal
awplus(config)# no ip source binding 192.168.1.2
```

To remove all static entries from the database, use the commands:

```
awplus# configure terminal
awplus(config)# no ip source binding
```

Related Commands

clear ip dhcp snooping binding
ip dhcp snooping binding
show ip dhcp snooping binding
show ip source binding

service dhcp-snooping

Use this command to enable the DHCP snooping service globally on the switch. This must be enabled before other DHCP snooping configuration commands can be entered.

Use the no variant of this command to disable the DHCP snooping service on the switch. This removes all DHCP snooping configuration from the running configuration, except for any DHCP snooping maximum bindings settings (ip dhcp snooping max-bindings command on page 78.18), and any DHCP snooping-based Access Control Lists (ACLs), which are retained when the service is disabled.

Syntax

```
service dhcp-snooping

no service dhcp-snooping
```

Default DHCP snooping is disabled on the switch by default.

Mode Global Configuration

Usage For DHCP snooping to operate on a VLAN, it must be enabled on the switch by using this command, and also enabled on the particular VLAN by using the ip dhcp snooping command on page 78.9.

For DHCP snooping to operate on a VLAN, it must:

- be enabled globally on the switch by using this command
- be enabled on the particular VLAN by using the ip dhcp snooping command on page 78.9
- have at least one port connected to a DHCP server configured as a trusted port by using the ip dhcp snooping trust command on page 78.20

If you disable the DHCP snooping service by using the no variant of this command, all DHCP snooping configuration (including ARP security, but excluding maximum bindings and ACLs) is removed from the running configuration, and the DHCP snooping database is deleted from active memory. If you re-enable the service, the switch:

- repopulates the DHCP snooping database from the dynamic lease entries in the database backup file (in NVS by default—see the ip dhcp snooping database command on page 78.15). The lease expiry times are updated.

The DHCP snooping service cannot be enabled on a switch that is configured with any of the following features, or vice versa:

- web authentication (auth-web enable command on page 65.28)
- roaming authentication (auth roaming enable command on page 65.17, auth roaming disconnected command on page 65.15)
- guest VLAN authentication (auth guest-vlan command on page 65.9).
- DHCP relay agent option (ip dhcp-relay agent-option command on page 86.14)

Any ACLs on a port that permit traffic matching DHCP snooping entries and block other traffic, will block all traffic if DHCP snooping is disabled on the port. If you disable DHCP snooping on the switch using this command, you must also remove any DHCP snooping ACLs from the ports to maintain connectivity (no access-group command on page 56.4).

Example To enable DHCP snooping on the switch, use the command:

```
awplus# configure terminal
awplus(config)# service dhcp-snooping
```

To disable DHCP snooping on the switch, use the command:

```
awplus# configure terminal
awplus(config)# no service dhcp-snooping
```

show arp security

Use this command to display ARP security configuration.

Syntax `show arp security`

Mode User Exec and Privileged Exec

Example To display ARP security configuration on the switch use the command:

```
awplus# show arp security
```

Figure 78-1: Example output from the **show arp security** command

```
awplus# show arp security

ARP Security Information:
  Total VLANs enabled ..... 2
  Total VLANs disabled ..... 11
  vlan1 ..... Disabled
  vlan2 ..... Disabled
  vlan3 ..... Disabled
  vlan4 ..... Disabled
  vlan5 ..... Disabled
  vlan100 ..... Disabled
  vlan101 ..... Disabled
  vlan102 ..... Disabled
  vlan103 ..... Disabled
  vlan104 ..... Disabled
  vlan105 ..... Enabled
  vlan1000 ..... Disabled
  vlan1001 ..... Enabled
```

Table 78-1: Parameters in the output from the **show arp security** command

Parameter	Description
`Total VLANs enabled`	The number of VLANs that have ARP security enabled.
`Total VLANs disabled`	The number of VLANs that have ARP security disabled.

Related Commands
arp security
show arp security interface
show arp security statistics

show arp security interface

Use this command to display ARP security configuration for the specified ports or all ports.

Syntax `show arp security interface [<port-list>]`

Parameter	Description
<port-list>	The ports to display ARP security information about. The port list can include switch ports, and static or dynamic aggregated links.

Mode User Exec and Privileged Exec

Example To display ARP security configuration for ports, use the command:

```
awplus# show arp security interface
```

Figure 78-2: Example output from the **show arp security interface** command

```
awplus#show arp security interface

Arp Security Port Status and Configuration:

  Port: Provisioned ports marked with brackets, e.g. (portx.y.z)
  KEY:  LG = Log
        TR = Trap
        LD = Link down

Port         Action
-------------------------------
port1.0.1    -- -- --
port1.0.2    -- -- --
port1.0.3    LG TR LD
port1.0.4    LG -- --
port1.0.5    LG -- --
port1.0.6    LG TR --
port1.0.7    LG -- LD
...
```

Table 78-2: Parameters in the output from the **show arp security interface** command

Parameter	Description
`Action`	The action the switch takes when it detects an ARP security violation on the port.
`Port`	The port. Parentheses indicate that ports are configured for provisioning.
`LG, Log`	Generate a log message
`TR, Trap`	Generate an SNMP notification (trap).
`LD, Link down`	Shut down the link.

Related Commands
arp security violation
show arp security
show arp security statistics
show log

snmp-server enable trap

show arp security statistics

Use this command to display ARP security statistics for the specified ports or all ports.

Syntax `show arp security statistics [detail] [interface <port-list>]`

Parameter	Description
`detail`	Display detailed statistics.
`interface <port-list>`	Display statistics for the specified ports.

Mode User Exec and Privileged Exec

Example To display the brief statistics for the ARP security, use the command:

```
awplus# show arp security statistics
```

Figure 78-3: Example output from the **show arp security statistics** command

```
awplus# show arp security statistics

DHCP Snooping ARP Security Statistics:

               In          In
 Interface     Packets     Discards
---------------------------------
 port1.0.3     20          20
 port1.0.4     30          30
 port1.0.12    120         0
```

Table 78-3: Parameters in the output from the **show arp security statistics** command

Parameter	Description
`Interface`	A port name. Parentheses indicate that ports are configured for provisioning.
`In Packets`	The total number of incoming APR packets that are processed by DHCP Snooping ARP Security
`In Discards`	The total number of ARP packets that are dropped by DHCP Snooping ARP Security.

Figure 78-4: Example output from the show arp security statistics detail command

```
awplus#show arp security statistics detail

DHCP Snooping ARP Security Statistics:

Interface ..................... port1.0.3
  In Packets .................. 20
  In Discards ................. 20
    No Lease .................. 20
    Bad Vlan .................. 0
    Bad Port .................. 0

show ip dhcp snooping agent-option

Use this command to display DHCP snooping Option 82 information for all interfaces, a specific interface or a range of interfaces.

Syntax `show ip dhcp snooping agent-option [interface <interface-list>]`

Parameter	Description
`interface`	Specify the interface.
`<interface-list>`	The name of the interface or interface range.

Mode User Exec and Privileged Exec

Examples To display DHCP snooping Option 82 information for all interfaces, use the command:

```
awplus# show ip dhcp snooping agent-option
```

To display DHCP snooping Option 82 information for `port1.0.1`, use the command:

```
awplus# show ip dhcp snooping agent-option interface
port1.0.1
```

To display DHCP snooping Option 82 information for `vlan1`, use the command:

```
awplus# show ip dhcp snooping agent-option interface
vlan1
```

To display DHCP snooping Option 82 information for `port2.0.1`, `port4.0.2` and ports in the range from `port4.0.10` to `port4.0.15`, use the command:

```
awplus# show ip dhcp snooping agent-option inteface
port2.0.1,port4.0.2,port4.0.10-port4.0.15
```

Output Figure 78-11: Example output from the **show ip dhcp snooping agent-option** command

```
awplus#show ip dhcp snooping agent-option

Table 78-4: Parameters in the output from the **show ip dhcp snooping binding** command

Parameter	Description
`Client IP Address`	The IP address of the DHCP client.
`MAC Address`	The MAC address of the DHCP client.
`Server IP Address`	The IP address of the DHCP server.
`VLAN`	The VLAN associated with this entry.
`Port`	The port the client is connected to.
`Expires (sec)`	The time in seconds until the lease expires.
`Type`	The source of the entry: ■ Dyna: dynamically entered by snooping DHCP traffic, configured by the ip dhcp snooping binding command, or loaded from the database backup file. ■ Stat: added statically by the ip source binding command
`Total number of bindings in database`	The total number of dynamic and static lease entries in the DHCP snooping database.

Table 78-6: Parameters in the output from the **show ip dhcp snooping statistics** command

Parameter	Description
`Interface`	The interface name.
`In Packets`	The total number of incoming packets that are processed by DHCP Snooping.
`In BOOTP Requests`	The total number of incoming BOOTP Requests.
`In BOOTP Replies`	The total number of incoming BOOTP Replies.
`In Discards`	The total number of incoming packets that have been discarded.
`Invalid BOOTP Information`	Packet contained invalid BOOTP information, such as an invalid BOOTP.OPCode.
`Invalid DHCP ACK`	A DHCP ACK message was discarded, for reasons such as missing Server Option or Lease Option.
`Invalid DHCP Release or Decline`	A DHCP Release or Decline message was discarded, for reasons such as mismatch between received interface and current binding information.
`Invalid IP/UDP Header`	A problem was detected in the IP or UDP header of the packet.
`Max Bindings Exceeded`	Accepting the packet would cause the maximum number of bindings on a port to be exceeded.
`Option 82 Insert Error`	An error occurred while trying to insert option 82 information.

Table 78-6: Parameters in the output from the **show ip dhcp snooping statistics** command(cont.)

Parameter	Description
`Option 82 Received Invalid`	The option 82 information received did not match the information inserted by DHCP Snooping.
`Option 82 Received On Untrusted Port`	A packet containing option 82 was received on an untrusted port.
`Option 82 Transmit On Untrusted Port`	A packet containing option 82 was to be sent on an untrusted port.
`Reply Received On Untrusted Port`	A BOOTP reply was received on an untrusted port.
`Source MAC/CHADDR Mismatch`	The L2 Source MAC address of the packet did not match the client hardware address field (BOOTP.CHADDR).
`Static Entry Already Exists`	An entry could not be added as a static entry already exists.

Introduction

This chapter describes the Virtual Router Redundancy Protocol (VRRP) feature provided by the switch, and how to configure the switch to participate in a virtual router.

One function of a switch is to act as a gateway to the WAN for hosts on a LAN. On larger LANs, two or more switches may act as the gateway, and hosts use a dynamic routing protocol, such as RIP or OSPF, to determine the gateway switch to use as the next hop in order to reach a specific IP destination. However, there are a number of factors, such as administrative or processing overhead, that may make it undesirable to use a dynamic routing protocol. One alternative is to use static routing; however, if the statically configured first hop switch fails, the hosts on the LAN are unable to communicate with those on the WAN.

The Virtual Router Redundancy Protocol defined in RFC 2338 provides a solution to the problem by combining two or more physical switches into a logical grouping called a virtual router (VR). The physical switches then operate together to provide a single logical gateway for hosts on the LAN.

Note If there are PIM-SM routers using VRRP the Bootstrap Router (BSR) function will not work properly.

Virtual Router Redundancy Protocol

The virtual router has a virtual MAC address that is known by all its participating switches or routers. The virtual MAC address is derived from the virtual router identifier - a user-defined value from 1 to 255. At the network level, all hosts on the LAN are configured with a common IP address that is used as the first hop. This IP address is typically owned by the virtual router's preferred individual switch or router. When available, this device performs the duties of the virtual router, and is referred to as the master. The switch that owns the IP address associated with the virtual router is referred to as the preferred master. When a virtual router is configured so that none of the participating switches owns the IP address, the virtual router has no preferred master.

When a switch takes the role of master for a virtual router, it is responsible for the following:

- Responding to ARP packets that contain IP addresses associated with the virtual router. The ARP response contains the virtual MAC address of the virtual router so that the hosts on the LAN associate the virtual MAC address with their configured first-hop IP address.
- Forwarding packets with a destination link layer MAC address equal to the virtual router MAC address.
- Accepting packets addressed to the IP addresses associated with the virtual router, but only if it actually owns the address(es).
- Broadcasting advertisement packets at regular intervals (at the specified advertisement interval) to inform backup switches that it is still acting as the master switch.

In accordance with the RFC standard, a user does not receive a response to ping or Telnet packets sent to the VR address unless the switch owns this address.

Each of the other switches participating in the virtual router is considered to be a backup switch. A switch can be part of several different virtual routers on one LAN, but all the virtual routers must have different virtual router identifiers (VRID). When a switch has the role of backup for a virtual router, it must be able to perform the following tasks:

- Receive advertisement packets from the master and check that the information contained in them is consistent with their own configuration; ignoring and discarding advertisement packets that do not match.
- Assume the role of master for the virtual router if an advertisement packet is not received for a given period, (the master-down time), based on the specified advertisement interval, (for example: awplus(config-router)# advertisement-interval 5 will set the advertisement-interval to 5 seconds). The master-down time is approximately three times the advertisement interval.
- Assume the role of master if it receives an advertisement packet from another switch with a lower priority than its own, and if preempt mode is on.

If the master switch fails, the backup switch assumes control and starts processing traffic.
If a backup switch is about to assume the role of master of the VR because it has not received an advertisement for the master-down period, it first checks the operational status of the interface to which the VR is attached. If the interface is down, it does not enter the master state. Instead, it stays in the backup state and checks the interface again after another master-down period, assuming it does not receive an advertisement during that time.

VRRP Configuration

VRRP is disabled by default. Once you have defined a virtual router session, you must enable VRRP to make the session operational for a given interface. You can then enable or disable the virtual router as shown:

To enable VRRP

`awplus(config)#`	
`router vrrp 1 vlan2`	Create a new VRRP session on the router, specify the virtual router ID (VRID) for the session, and specify the interface (`vlan2`) that will participate in virtual routing.
`awplus(config-router)#`	
`enable`	Enable the VRRP session on the switch.
`awplus(config-router)#`	
`exit`	Return to the Global Configuration mode.
`awplus(config)#`	Global Configuration mode prompt.

To disable VRRP

`awplus(config)#`	
`router vrrp 1 vlan2`	Specify an existing VRRP session, specify the virtual router ID (VRID) for the session, and specify the interface (`vlan2`) that will participate in virtual routing.
`awplus(config-router)#`	
`disable`	Disable the VRRP session on the switch.
`awplus(config-router)#`	
`exit`	Return to the Global Configuration mode.
`awplus(config)#`	Global Configuration mode prompt.

A virtual router must be defined on at least two switches before it operates correctly. Use the following steps to configure virtual routing on a switch. Note that this example assumes that VLAN 2 already exists on the switch. See "Configuring VLANs" on page 16.3.

To configure virtual routing on a switch

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`router vrrp 1 vlan2`	Create a new VRRP session on the router, specify the VRID for the session, and specify the interface (vlan2) that will participate in virtual routing.

To configure virtual routing on a switch(cont.)

`awplus(config-router)#`	
`virtual-ip 10.10.10.50 master`	Set the virtual IP address for the VRRP session. Define the default state (master or backup) of the VRRP router within the virtual router.
`awplus(config-router)#`	
`priority 255`	Set the VRRP priority for the switch.
`awplus(config-router)#`	
`enable`	Enable the VRRP session on the switch.
`awplus(config-router)#`	
`exit`	Return to the Global Configuration mode.
`awplus(config)#`	Global Configuration mode prompt.

To destroy a virtual router on the LAN, it must be removed from all participating switches. Use the following commands to remove a virtual router so that the switch no longer participates in virtual routing.

To remove the virtual router VRRP 1 from a switch

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`no router vrrp 1 vlan2`	Remove the VRRP session on the switch for the specified interface `vlan2`.
`awplus(config-router)#`	
`exit`	Return to the Global Configuration mode.
`awplus(config)#`	Global Configuration mode prompt.

Alternatively, you can simply disable the virtual router and retain the configuration.

To disable the router and retain the configuration

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`router vrrp 1 vlan2`	Select the VRRP session on the switch, specify the VRID for the session, and specify the interface (`vlan2`) used for virtual routing.
`awplus(config-router)#`	
`disable`	Disable the VRRP session on the switch.
`awplus(config-router)#`	
`exit`	Return to the Global Configuration mode.
`awplus(config)#`	Global Configuration prompt.

VRRP election and preempt

If the switch that is the current VRRP master becomes unavailable, the master role is taken by the switch with the next highest priority. The priority is a value from 1 to 255, with a default of 100. The value 255 is reserved for the switch that owns the virtual router's IP address. The new master takes over all the responsibilities of the original master.

By default, when a switch becomes available that has a higher priority than the master, this switch takes over as master. This is referred to as preempt mode and can be set on or off. Even with preempt mode off, the switch that owns the IP address always becomes the master when available. Preempt mode should be the same for all switches in the virtual router.

If two switches are configured with the same priority and a conflict occurs when they both transition to master simultaneously, the one with the highest IP address has higher priority. Due to timing differences the conflict may not always occur and simply the first switch to respond will become the master.

Hosts on the LAN can continue sending packets to the virtual MAC address they originally associated with the first hop IP address, even though the switch that owns the IP address is not currently available. When the original switch becomes available again, and if it is a preferred switch (i.e. it owns the virtual router IP address) then it resumes the role of master.

Use the following commands to set the priority and preempt mode when you create the virtual router:

To set the priority and preempt mode for VRRP 1

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`router vrrp 1 vlan2`	Select the VRRP session on the switch, specify the VRID for the session, and specify the interface (`vlan2`) used for virtual routing.
`awplus(config-router)#`	
`priority 255`	Set the VRRP priority for the switch
`awplus(config-router)#`	
`preempt true`	Select the preempt mode for VRRP 1.
`awplus(config-router)#`	
`enable`	Enable the VRRP session on the switch.
`awplus(config-router)#`	
`exit`	Return to the Global Configuration mode.
`awplus(config)#`	Global Configuration prompt

The advertisement interval determines the rate that the master sends its advertisement packets. This rate must be the same value for all switches in the virtual router. The default advertisement interval of 1second can be used for most networks. However, you can modify this interval by using the advertisement-interval command, as shown in the following procedure:

To set the advertisement interval to 5 seconds on VRRP1

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config#`	
`router vrrp 1 vlan2`	Select the VRRP session on the switch, specify the VRID for the session, and specify the interface (`vlan2`) used for virtual routing.
`awplus(config-router)#`	
`advertisement-interval 5`	Set the advertisement interval to `5` seconds.

VRRP authentication

Each of the switches in the virtual router can be configured for plaintext authentication, or no authentication. Authentication is appropriate where there is either a security risk, or the configuration is complex.

Plaintext password authentication protects against accidental miscommunication and prevents a switch from inadvertently backing up another switch. This kind of miscommunication could occur, for example, where multiple virtual routers exist on the same LAN.

The authentication type and, in the case of plaintext authentication, the password, must be the same for all switches in the virtual router. By default, the virtual router has no authentication. Authentication must be defined against the relevant interface in the interface configuration mode as shown: This example assumes that VLAN 2 already exists on the switch. See “Configuring VLANs” on page 16.3.

To set the authentication string “guest” to VLAN 2

`awplus(config)#`	
`router vrrp 1 vlan2`	Enable VRRP on the switch, specify the VRID for the session, and specify the interface (`vlan2`) used for virtual routing.
`awplus(config-if)#`	
`ip vrrp authentication mode text`	Apply text mode authentication to interface `vlan2`.
`awplus(config-if)#`	
`ip vrrp authentication string guest`	Specify the authentication string or password used by the key.
`Switch_A(config-if)#`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.
`awplus(config)#`	
`exit`	Return to the Privileged Exec mode prompt
`awplus#`	Privileged Exec mode prompt

In order to maintain consistent authentication level, each switch in the virtual router must have at least the minimum allowable level of security that meets the network environment.

VRRP debugging

VRRP debugging displays data that is useful for troubleshooting. To enable or disable debugging use the following commands:

To select and deselect VRRP debugging

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`debug vrrp [all|events|packet]`	Enable the selected debugging type.
`awplus(config)#`	
`no debug vrrp [all|events|packet]`	Disable the selected debugging type.

It is important that all switches involved in a virtual router are configured with the same values for the following:

- VRRP virtual router identifier
- IP address
- advertisement interval
- preempt mode
- authentication type
- password

Inconsistent configuration causes advertisement packets to be rejected and the virtual router cannot perform properly.

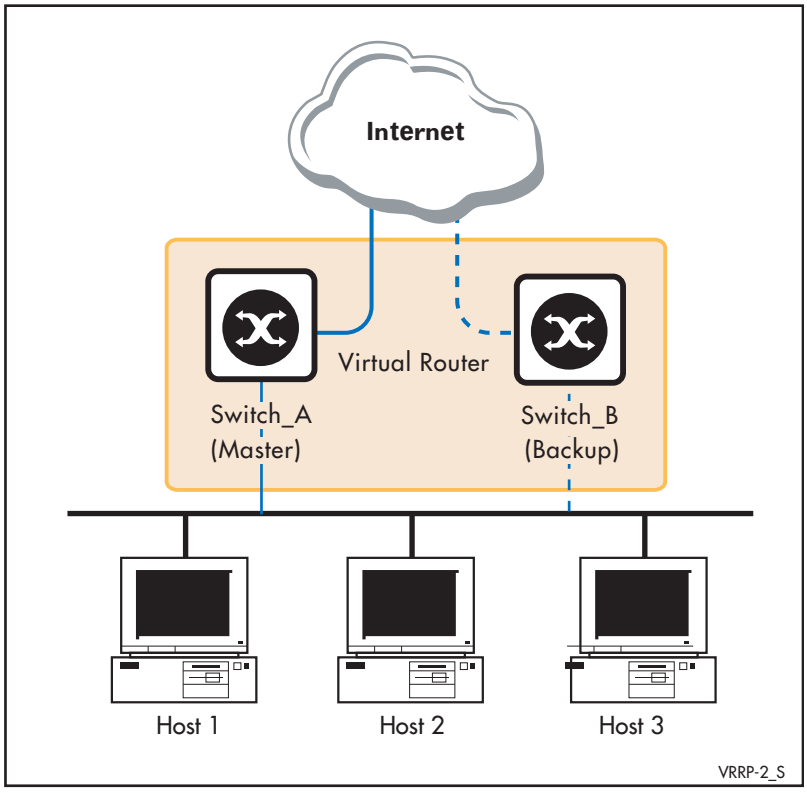
Configuration examples

The following examples show how to configure a virtual router in a LAN:

- Preferred Master with Backup Switch
- Authenticated Virtual Router with No Preferred Master

Master with backup switch

This example show how to configure a basic virtual router with a preferred master and a backup.



Switch_A owns the IP address of the virtual router, and always assumes the role of master whenever it is available. Switch_B is the backup, and assumes the role of master, backing up this IP address if A becomes unavailable. No authentication is used for this simple virtual router.

Step 1: Configure Switch_A

At this point we assume that you have already created VLAN 2 on Switch_A. See "Configuring VLANs" on page 16.3.

Configure IP

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`hostname Switch_A`	Assign a host name to `Switch_A`.
`Switch_A(config)#`	
`interface vlan2`	Specify the interface (`vlan2`) that will participate in virtual routing to first configure an IP address for `vlan2`.
`Switch_A(config-if)#`	
`ip address 192.168.1.1/24`	Specify the IP address and mask for interface `vlan2`.

Create the Virtual Router

`Switch_A(config)#`	
`spanning-tree mode stp`	Configure STP for interfaces on `Switch_A`.
`Switch_A(config)#`	
`router vrrp 1 vlan2`	Create a new VRRP session on the router, specify the VRID for the session, and specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_A(config-router)#`	
`virtual-ip 192.168.1.1 master`	Set the virtual IP address for the VRRP session. Define the default state of the VRRP router within the virtual router.
`Switch_A(config-router)#`	
`enable`	Enable the VRRP session on the router.
`Switch_A(config-router)#`	
`exit`	Exit the Router Configuration mode and enter the Global Configuration mode.
`Switch_A(config)#`	
`exit`	Exit the Global Configuration mode and enter the Privileged Exec mode.
`Switch_A#`	Privileged Exec mode prompt.

Step 2: Configure Switch_B

At this point we assume that you have already created VLAN 2 on Switch_B. See "Configuring VLANs" on page 16.3.

Configure IP

`awplus#`	
`configure terminal`	Enter Global Configuration mode.
`awplus(config)#`	
`hostname Switch_B`	Assign a host name to `Switch_B`.
`Switch_B(config)#`	
`interface vlan2`	Specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_B(config)#`	
`ip address 192.168.1.2/24`	Specify the IP address and mask for interface

Create the Virtual Router

`Switch_B(config)#`	
`router vrrp 1 vlan2`	Create a new VRRP session on the router, specify the VRID for the session, and specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_B(config-router)#`	
`virtual-ip 192.168.1.1 backup`	Set the virtual IP address for the VRRP session. Define the default state of the VRRP router within the virtual router.
`Switch_B(config-router)#`	
`enable`	Enable the VRRP session on the router.
`Switch_B(config-router)`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.
`Switch_B(config)#`	
`exit`	Return to the Privileged Exec mode.
`Switch_B#`	Privileged Exec mode prompt.

Authenticated Virtual Router with an Independent Preferred Master

This example shows how to configure a virtual router with its own IP address. The address is not owned by any of the switches participating in the virtual router. Switch A has a higher priority for becoming the master, Switch B has the next highest priority, and Switch C takes the master role when A or B are unavailable. The default preempt mode (preempt on) ensures that the switch with the highest priority (when it is available) always takes the master role from a lower priority switch acting as master. Plaintext authentication protects against accidental misconfiguration.

Although the switch with the highest priority will be master, it is important to remember that when creating VRRP you must also define the default role. In the following example Switch_A will be defined as being the master.

At this point we assume that you have already created VLAN 2 on Switches A, B and C. See "Configuring VLANs" on page 16.3.

Step 1: Configure IP

On switch_A, add an IP interface to the virtual router.

`awplus#`	
`configure terminal`	Enter Global Configuration mode.
`awplus(config)#`	
`hostname Switch_A`	Assign a host name to `Switch_A`.
`Switch_A(config)#`	
`interface vlan2`	Specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_A(config)#`	
`ip address 192.168.1.1/24`	Add the IP address and mask for interface `vlan2`.

On switch_B, add a different IP interface to virtual router.

`awplus#`	
`configure terminal`	Enter Global Configuration mode.
`awplus(config)#`	
`hostname Switch_B`	Assign a host name to `Switch_B`.
`Switch_B(config)#`	
`interface vlan2`	Specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_B(config)#`	
`ip address 192.168.1.2/24`	Add the IP address and mask for interface `vlan2`.

On switch_C, add a third IP interface to the virtual router.

`awplus#`	
`configure terminal`	Enter Global Configuration mode.
`awplus(config)#`	
`hostname Switch_C`	Assign a host name to `Switch_C`.
`Switch_C(config)#`	
`interface vlan2`	Specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_C(config)#`	
`ip address 192.168.1.3/24`	Add the IP address and mask for interface `vlan2`.

Step 2: Create the virtual router

On switch A, create virtual router `vrrp2` with IP address `192.168.1.4`, plaintext authentication with password `trip4e`, and a high priority.

To configure the virtual router on switch_A

`Switch_A#`	
`configure terminal`	Enter the Global Configuration mode.
`Switch_A(config)#`	
`router vrrp2 vlan2`	Create a new VRRP session on the router, specify the VRID for the session, and specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_A(config-router)#`	
`virtual-ip 192.168.1.4 backup`	Set the virtual IP address for the VRRP session. Define the default state of the VRRP router within the virtual router.
`Switch_A(config-router)#`	
`preempt-mode on`	Turn on preempt mode.
`Switch_A(config-router)#`	
`priority 254`	Set the VRRP priority of 254 for the switch.
`Switch_A(config-router)#`	
`enable`	Enable VRRP on the switch.
`Switch_A(config-router)#`	
`exit`	Return to the Global Configuration mode.
`Switch_A(config)#`	
`interface vlan2`	Specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_A(config-if)#`	
`ip vrrp authentication mode text`	Apply text mode authentication to `vlan2`.

To configure the virtual router on switch_A

`Switch_A(config-if)#`	
`ip vrrp authentication string trip4e`	Specify the authentication string `trip4e` used by the key.
`Switch_A(config)#`	
`exit`	Return to the Privileged Exec mode prompt.
`Switch_A#`	Privileged Exec mode prompt.

On switch B, create the same virtual router, but with a lower priority.

To configure the virtual router on switch_B

`Switch_B#`	
`configure terminal`	Enter the Global Configuration mode.
`Switch_B(config)#`	
`router vrrp2 vlan2`	Create a new VRRP session on the router, specify the VRID for the session, and specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_B(config-router)#`	
`virtual-ip 192.168.1.4 backup`	Set the virtual IP address for the VRRP session. Define the default state of the VRRP router within the virtual router.
`Switch_B(config-router)#`	
`preempt-mode on`	Turn on preempt mode.
`Switch_B(config-router)#`	
`priority 200`	Set the VRRP priority of 200 for the switch.
`Switch_B(config-router)#`	
`enable`	Enable VRRP on the switch.
`Switch_A(config-router)#`	
`exit`	Return to the Global Configuration mode.
`Switch_B(config)#`	
`interface vlan2`	Specify the interface (`vlan2`) that will participate in virtual routing.

To configure the virtual router on switch_B

`Switch_B(config-if)#`	
`ip vrrp authentication mode text`	Apply text mode authentication to `vlan2`.
`Switch_B(config-if)#`	
`ip vrrp authentication string trip4e`	Specify the authentication string `trip4e` used by the key.
`Switch_B(config-if)#`	
`exit`	Return to the Global Configuration mode.
`Switch_B(config)#`	
`exit`	Return to the Privileged Exec mode prompt.
`Switch_B#`	Privileged Exec mode prompt.

On switch C, create the same virtual router with the default priority of 100.

To configure the virtual router on switch_C

`Switch_C#`	
`configure terminal`	Enter the Global Configuration mode.
`Switch_C(config)#`	
`router vrrp2 vlan2`	Create a new VRRP session on the router, specify the VRID for the session, and specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_C(config-router)#`	
`virtual-ip 192.168.1.4 backup`	Set the virtual IP address for the VRRP session. Define the default state (master or backup) of the VRRP router within the virtual router.
`Switch_C(config-router)#`	
`preempt-mode on`	Turn on preempt mode.
`Switch_C(config-router)#`	
`priority 100`	Set the VRRP priority of 100 for the switch.
`Switch_C(config-router)#`	
`enable`	Enable VRRP on the switch.
`Switch_A(config-router)#`	
`exit`	Return to the Global Configuration mode.
`Switch_C(config)#`	
`interface vlan2`	Specify the interface (`vlan2`) that will participate in virtual routing.
`Switch_C(config-if)#`	
`ip vrrp authentication mode text`	Apply text mode authentication to `vlan2`.
`Switch_C(config-if)#`	
`ip vrrp authentication string trip4e`	Specify the authentication string `trip4e` used by the key.
`Switch_B(config-if)#`	
`exit`	Return to the Global Configuration mode.
`Switch_C(config)#`	
`exit`	Return to the Privileged Exec mode prompt
`Switch_C#`	Privileged Exec mode prompt

The default preempt mode ensures that the highest priority switch available always takes the master role. However, if there are no significant disadvantages to the lower priority switches having the master role, and if changes where the switch takes the master role are to be avoided (for example, when a high cost is associated with each change) then you should instead set the preempt mode to off.

Chapter 80: VRRP Commands

Command List 80.2
advertisement-interval 80.2
circuit-failover 80.3
debug vrrp 80.4
debug vrrp events 80.4

vrrp vmac 80.20

Command List

This chapter provides an alphabetical reference for commands used to configure the Virtual Router Redundancy Protocol (VRRP). For more information, see Chapter 79, VRRP Introduction and Configuration.

For information about modifying or redirecting the output from show commands to a file, see "Controlling "show" Command Output" on page 1.41.

advertisement-interval

Use this command to configure the advertisement interval of the virtual router. This is the length of time, in seconds, between each advertisement sent from the master to its backup(s).

Use the no variant of this command to remove an advertisement interval of the virtual router, which has been set using the advertisement-interval command.

Syntax

```
advertisement-interval <1-255>
no advertisement-interval
```

Parameter	Description
<1-255>	Specifies the advertisement interval in seconds.

Default The default advertisement interval is 1 second.

Mode Router Configuration

Example

```
awplus# configure terminal
awplus(config)# router vrrp 5 vlan2
awplus(config-router)# interface vlan2
awplus(config-router)# advertisement-interval 6

awplus# configure terminal
awplus(config)# router vrrp 5
awplus(config-router)# interface vlan2
awplus(config-router)# no advertisement-interval
```

circuit-failover

Use this command to enable the VRRP circuit failover feature.

Use the no variant of this command to disable this feature.

Syntax

```
circuit-failover <interface> <1-253>
no circuit-failover [<interface> <1-253>]
```

Parameter	Description
<interface>	The interface of the router that will participate in the virtual router. Interface must exist on the router.
<1-253>	Delta value. The value by which virtual routers decrement their priority value during a circuit failover event. Configure this value to be greater than the difference of priorities on the master and backup routers.

Mode Router Configuration

Example

```
awplus# configure terminal
awplus(config)# router vrrp 1
awplus(config-router)# interface vlan1
awplus(config-router)# circuit-failover vlan2 30

awplus# configure terminal
awplus(config)# router vrrp 1
awplus(config-router)# interface vlan1
awplus(config-router)# no circuit-failover
```

Related Commands router vrrp (interface)

debug vrrp

Use this command to specify debugging options for VRRP. The all parameter turns on all the debugging options.

Use the no variant of this command to disable this function.

Syntax

```
debug vrrp [all]
no debug vrrp [all]
```

Mode Privileged Exec and Global Configuration

Examples

```
awplus# configure terminal
awplus(config)# debug vrrp all

awplus# configure terminal
awplus(config)# no debug vrrp
```

Related Commands undebug vrrp

debug vrrp events

Use this command to specify debugging options for VRRP event troubleshooting.

Use the no variant of this command to disable this function.

Syntax

```
debug vrrp events
no debug vrrp events
```

Mode Privileged Exec and Global Configuration

Usage The debug vrrp events command enables the display of debug information related to VRRP internal events.

Examples

```
awplus# configure terminal
awplus(config)# debug vrrp events

awplus# configure terminal
awplus(config)# no debug vrrp events
```

Related Commands undebug vrrp events

debug vrrp packet

Use this command to specify debugging options for VRRP packets.

Use the no variant of this command to disable this function.

Syntax

```
debug vrrp packet [send|recv]
no debug vrrp packet [send|recv]
```

Parameter	Description
send	Specifies the debug option set for sent packets.
recv	Specifies the debug option set for received packets.

Mode Privileged Exec and Global Configuration

Usage The debug vrrp packet command enables the display of debug information related to the sending and receiving of packets.

Examples

```
awplus# configure terminal
awplus(config)# debug vrrp packet send

awplus# configure terminal
awplus(config)# no debug vrrp packet
```

Related Commands undebug vrrp packet

disable (VRRP)

Use this command to disable a VRRP session on the router to stop it participating in virtual routing.

Syntax `disable`

Mode Router Configuration

Example

```
awplus# configure terminal
awplus(config)# router vrrp 5
awplus(config-router)# interface vlan2
awplus(config-router)# disable
```

Related Commands enable (VRRP)

enable (VRRP)

Use this command to enable the VRRP session on the router to make it participate in virtual routing.

Syntax `enable`

Mode Router Configuration

Usage You must configure the virtual IP address and define the interface for the VRRP session (using the virtual-ip and interface commands) before using this command.

Example

```
awplus# configure terminal
awplus(config)# router vrrp 5
awplus(config-router)# interface vlan2
awplus(config-router)# enable
```

Related Commands disable (VRRP)
show vrrp

interface (VRRP) (deprecated)

This command has been deprecated and will be removed in a later software version.

Use the router vrrp (interface) command to configure VRRP and define the interface that will participate in virtual routing to send and receive advertisement messages.

Use this command to define the physical interface that will participate in virtual routing. This interface is used for two purposes - to send/receive advertisement messages and to forward on behalf of the virtual router when in master state. Note that you can also specify the interface within the circuit-failover and the router vrrp commands without specifying the interface later.

Syntax `interface <interface>`

Parameter	Description
<interface>	Specify the name of the interface that will participate in the virtual routing. Interface must exist on the router.

Mode Router Configuration

Usage Use the no variant of this command to remove the specified interface from participating in virtual routing. Note that the interface is now specified in the router vrrp (interface) command.

Example To configure an interface on which VRRP is enabled enter the commands shown below:

```
awplus# configure terminal
awplus(config)# router vrrp 5
awplus(config-router)# interface vlan2
```

Related Commands router vrrp (interface)

ip vrrp authentication mode

Use this command to enable clear text password authentication used for VRRP packets.

Use the ip vrrp authentication string command after this command to specify the password.

Use the no variant of this command to reset to the default of no text authentication.

Syntax

```
ip vrrp authentication mode text
no ip vrrp authentication mode [text]
```

Parameter	Description
`text`	Specifies the clear text or simple password authentication.

Default No text authentication.

Mode Interface Configuration for a VLAN interface.

Usage RFC 3768 *Virtual Router Redundancy Protocol (VRRP)* recommends no authentication. VRRP authentication commands are available for backwards compatibility the earlier VRRP RFC 2338.

See "VRRP authentication" on page 79.7 for further information about VRRP Authentication.

Examples The following example shows text authentication configured on the `vlan2` interface ensuring authentication packets received on this interface.

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ip vrrp authentication mode text
```

The following example resets to the default setting for no text authentication on `vlan2`.

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# no ip vrrp authentication mode
```

Related Commands ip vrrp authentication string

ip vrrp authentication string

Use this command to specify the authentication string or password used by a key.

Use this command after ip vrrp authentication mode that enables clear text authentication.

Use the no variant of this command to remove a configured authentication string.

Syntax

```
ip vrrp authentication string <password>
no ip vrrp authentication string
```

Parameter	Description
<password>	The authentication string or password.

Mode Interface Configuration for a VLAN interface.

Example In the following example, the interface `vlan2` is configured to have an authentication string as `guest`, any receiving packet in that interface should have the same string as password.

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# ip vrrp authentication mode text
awplus(config-if)# ip vrrp authentication string guest
```

See "VRRP authentication" on page 79.7 for further information about VRRP Authentication.

Related Commands ip vrrp authentication mode

preempt-mode

Use this command to configure preempt mode. If set to true, the highest priority backup will always be the master when the default master is unavailable. If set to false, a higher priority backup will not preempt a lower priority backup who is acting as master.

Syntax `preempt-mode {true|false}`

Parameter	Description
`true`	Preemption enabled.
`false`	Preemption disabled.

Default The default is true.

Mode Router Configuration

Usage When the master router fails, the backup routers come online in priority order—highest to lowest. Preempt mode means that a higher priority back up router will take over the master role from a lower priority back up. Preempt mode on true allows a higher priority backup router to relieve a lower priority backup router.

See "VRRP election and preempt" on page 79.6 for further information on preempt mode.

Example

```
awplus# configure terminal
awplus(config)# router vrrp 4
awplus(config-router)# interface vlan2
awplus(config-router)# preempt-mode false
```

Related Commands circuit-failover
priority

priority

Use this command to configure the VRRP router priority within the virtual router. The highest priority router is Master (unless preempt-mode is false).

Use the no variant of this command to remove the VRRP router priority within the virtual router, which has been set using the priority command.

Syntax

```
priority <1-255>
no priority
```

Parameter	Description
<1-255>	The priority. For the master router, use 255 for this parameter; otherwise use any number from the range <1-254>.

Default Defaults for priority are: master router = 255; backup = 100.

Mode Router Configuration

Example

```
awplus# configure terminal
awplus(config)# router vrrp 3
awplus(config-router)# interface vlan2
awplus(config-router)# priority 101
```

Related Commands circuit-failover
preempt-mode

router vrrp (interface)

Use this command to configure VRRP and define the interface that will participate in virtual routing to send and receive advertisement messages. This command allows you to enter the Router Configuration mode.

Use the no variant of this command to remove the VRRP configuration. Disable the VRRP session before using the no variant of this command.

Syntax

```
router vrrp <vrid> <interface>
no router vrrp <vrid> <interface>
```

Parameter	Description
<vrid>	*<1-255>* The ID of the virtual router session to create.
<interface>	Specify the name of the interface that will participate in the virtual routing. The interface must exist on the router.

Mode Global Configuration

Usage Use the required *<interface>* placeholder to define the interface that will participate in virtual routing. This interface is used for two purposes - to send/receive advertisement messages and to forward on behalf of the virtual router when in master state.

Example

```
awplus# configure terminal
awplus(config)# router vrrp 5 vlan2
awplus(config-router)#

awplus# configure terminal
awplus(config)# no router vrrp 5 vlan2
awplus(config-router)#
```

Related Commands circuit-failover
interface (VRRP) (deprecated)

show debugging vrrp

Use this command to display the set VRRP debugging option.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show debugging vrrp`

Mode User Exec and Privileged Exec

Example

```
awplus# show debugging vrrp
```

show running-config router vrrp

Use this command to show the configuration for VRRP.

Note This command is available only if VRRP is enabled.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show running-config router vrrp`

Mode Privileged Exec, Global Configuration, Line Configuration, and Interface Configuration.

Example

```
awplus# show running-config router vrrp
```

Output Figure 80-1: Example output from the **show running-config router vrrp** command

```
!
router vrrp 2 vlan2
 circuit-failover vlan1 3
 advertisement-interval 4
!
```

show vrrp

Use this command to display information about all VRRP sessions. This command shows a summary when the optional brief parameter is used.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show vrrp [brief]`

Parameter	Description
`brief`	Brief summary of VRRP sessions.

Mode User Exec and Privileged Exec

Example To display information about all VRRP sessions, enter the command:

```
awplus# show vrrp
```

To display brief summary output about VRRP sessions, enter the command:

```
awplus# show vrrp brief
```

Output Figure 80-2: Example output from the **show vrrp** command

```
awplus#show vrrp
VrId <1>
 State is Master
 Virtual IP is 10.0.0.222 (Not IP owner)
 Interface is vlan2
 Priority is 100
 Advertisement interval is 1 sec
 Preempt mode is TRUE
```

Figure 80-3: Example output from the **show vrrp brief** command

```
awplus#show vrrp brief
Interface        Grp  Prio Own  Pre  State      Master addr      Group addr
 vlan10            1   200   N    P  Master     192.168.10.4     192.168.10.253
 vlan10            2   150   N    P  Backup     192.168.10.4     192.168.10.254
 vlan11            3   200   N    P  Master     192.168.11.4     192.168.11.253
 vlan11            4   150   N    P  Backup     192.168.11.4     192.168.11.254
```

Related Commands enable (VRRP)

show vrrp counters

This command displays VRRP SNMP counters on the console, as described in the VRRP MIB and RFC2787, for debugging use while you configure VRRP with commands in this chapter.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show vrrp counters`

Mode User Exec and Privileged Exec

Usage The output has a section for global counters and a section of counters for each VRRP instance configured. See the descriptions of the counters below the sample output as per RFC2787.

Note Note that the counters displayed with this commands are the same counters as described in RFC 2787 (Copyright (C) The Internet Society (2000). All Rights Reserved) except for the `Monitored Circuit Up` and `Monitored Circuit Down` counters which are additions beyond the MIB.

Example To display information about VRRP SNMP counters on the console, enter the command:

```
awplus# show vrrp counters
```

Figure 80-4: Example output from the **show vrrp counters** command

```
awplus#show vrrp counters
VRRP Global Counters:
  Checksum Errors .... 230
  Version Errors ..... 0
  VRID Errors ........ 230

  Monitored Circuit Up ...... 0
  Monitored Circuit Down..... 2
```

Table 80-1: Global counters with descriptions for the **show vrrp counters** command:

Counter	Description
Checksum Errors	The total number of VRRP packets received with an invalid VRRP checksum value.
Version Errors	The total number of VRRP packets received with an unknown or unsupported version number.
VRID Errors	The total number of VRRP packets received with an invalid VRID for this virtual router.

Table 80-2: Per VR counters with descriptions for the **show vrrp counters** command:

Counter	Description
Master Transitions	The total number of times that this virtual router's state has transitioned to MASTER.
Received Advertisements	The total number of VRRP advertisements received by this virtual router.
Internal Errors	The total number of VRRP advertisement packets received for which the advertisement interval is different than the one configured for the local virtual router.
TTL Errors	The total number of VRRP packets received by the virtual router with IP TTL (Time-To-Live) not equal to 255.
Received Priority 0 Pkt	The total number of VRRP packets received by the virtual router with a priority of '0'.
Sent Priority 0 Pkt	The total number of VRRP packets sent by the virtual router with a priority of '0'.
Received Invalid Type	The number of VRRP packets received by the virtual router with an invalid value in the 'type' field.
Address List Errors	The total number of packets received for which the address list does not match the locally configured list for the virtual router.
Packet Length Errors	The total number of packets received with a packet length less than the length of the VRRP header.
Invalid Authentications	The total number of packets received with an unknown authentication type.
Authentication Mismatch	The total number of packets received with 'Auth Type' not equal to the locally configured authentication method
Authentication Failures	The total number of VRRP packets received that do not pass the authentication check.
Monitored Circuit Up	The total number of times the monitored circuit has generated the UP event.
Monitored Circuit Down	The total number of times the monitored circuit has generated the down event.

show vrrp (session)

Use this command to display information for a particular VRRP session.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show vrrp <vrid> <interface>`

Parameter	Description
<vrid>	*<1-255>* The virtual router ID for which to display information. Session must already exist.
<interface>	The interface to display information about, for instance, `vlan2`.

Mode User Exec and Privileged Exec

Usage See the below sample output from the show vrrp command displaying information about VRRP session 1 configured on vlan2. Output shows that a Virtual IP address has been set.

```
awplus# show vrrp 1 vlan2
```

```
awplus#show vrrp 1 vlan2
Address family IPv4
VrId <1>
 Interface is vlan2
 State is Initialize
 Virtual IP address is 10.10.11.250 (Not IP owner)
 Priority is 100
 Advertisement interval is 1 sec
 Preempt mode is TRUE
```

See the below sample output from the show vrrp command displaying information about VRRP session 1 configured on vlan3. Output shows a Virtual IP address has not been set yet.

```
awplus# show vrrp 1 vlan3
```

```
awplus#show vrrp 1 vlan3
Address family IPv4
VrId <1>
 Interface is vlan3
 State is Initialize
 Virtual IP address is unset
 Priority is 100
 Advertisement interval is 1 sec
 Preempt mode is TRUE
```

Example The following command shows information about VRRP session 5 for interface vlan2.

```
awplus# show vrrp 5 vlan2
```

undebug vrrp

Use this command to disable all VRRP debugging.

Syntax `undebug vrrp all`

Mode Privileged Exec

Example

```
awplus# undebug vrrp all
```

Related Commands debug vrrp

undebug vrrp events

Use this command to disable debugging options for VRRP event troubleshooting.

Syntax `undebug vrrp events`

Mode Privileged Exec

Example

```
awplus# undebug vrrp events
```

Related Commands debug vrrp events

undebug vrrp packet

Use this command to disable debugging options for VRRP packets.

Syntax `undebug vrrp packet [send|recv]`

Parameter	Description
`send`	Disable the debug option set for sent packets.
`recv`	Disable the debug option set for received packets.

Mode Privileged Exec

Example

```
awplus# undebug vrrp packet send
```

Related Commands debug vrrp packet

virtual-ip

Use this command to set the virtual IP address for the VRRP session. This is the IP address of the virtual router that end hosts set as their default gateway.

Use the no variant of this command to disable this feature.

Syntax

```
virtual-ip <ip-address> master
virtual-ip <ip-address> backup
no virtual-ip
```

Parameter	Description
<ip-address>	The virtual IP address of the virtual router, entered in the format A.B.C.D.
master	Sets the default state of the VRRP router within the Virtual Router as master. For master, the router must own the Virtual IP address.
backup	Sets the default state of the VRRP router within the Virtual Router as backup.

Mode Router Configuration

Example

```
awplus# configure terminal
awplus(config)# router vrrp 5
awplus(config-router)# interface vlan2
awplus(config-router)# virtual-ip 192.0.2.30 master
```

vrrp vmac

Use this command to enable or disable the Virtual MAC feature.

Syntax `vrrp vmac {enable|disable}`

Mode Global Configuration

Example To enable Virtual MAC enter:

```
awplus# configure terminal
awplus(config)# vrrp vmac enable
```

To disable Virtual MAC enter:

```
awplus# configure terminal
awplus(config)# vrrp vmac disable
```

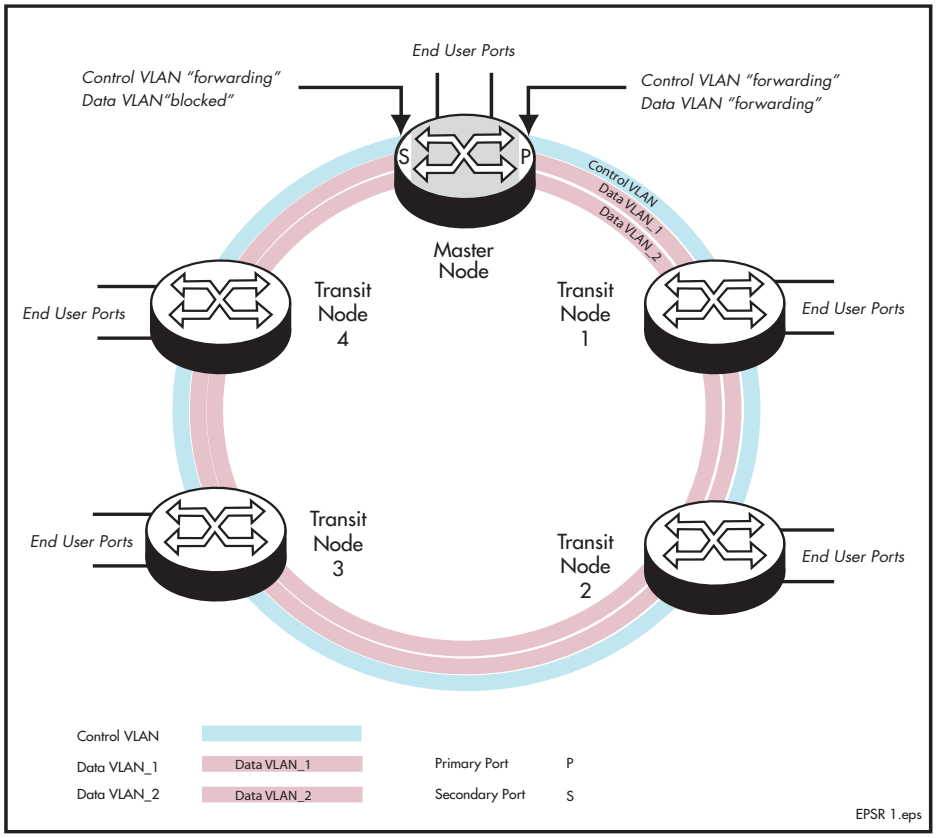
Introduction

Ethernet Protection Switching Ring (EPSR) is a protection system that prevents loops within Ethernet ring based topologies. EPSR offers a rapid detection and recovery time (in the order of 50 ms, depending on configuration) if a link or node fails. This rapid recovery time makes EPSR a more effective alternative to spanning tree options when using ring-based topologies to create high speed resilient Layer 2 networks.

Ring Components and Operation

EPSR operates only on ring-based topologies. An EPSR ring comprises a series of nodes (Ethernet bridges) connected end to end. The figure below shows a basic ring configuration. A ring comprises one master node and a number of transit nodes. Each node connects to the ring via two ports. On the master node one port is configured to be the primary port and the other, the secondary port.

Figure 81-1: Simple EPSR ring configuration



EPSR instances and domains

Each physical EPSR ring contains one or more EPSR domains. An EPSR instance can be thought of as a component of an EPSR ring domain that exists on a single node. A set of instances across the whole ring is called a "domain." Therefore a ring whose individual nodes each have two instances results in a two domain ring. Each instance contains a control VLAN and a number of data VLANs.

The EPSR control VLAN and its associated data VLANs form a Ring Domain. Although a physical ring can have more than one domain, each domain must operate as a separate logical group of VLANs and must have its own master node. This means that several domains may share the same physical network, but must operate as logically separate VLAN groups.

Control VLAN The function of the control VLAN is to monitor the ring domain and maintain its operational functions. To do this it transmits and monitors operational healthcheck messages using EPSR healthcheck control frames. The control VLAN carries no user data.

Caution

Specifying the Access Control List (ACL) filter action, send-to-cpu, could result in EPSR healthcheck messages and other control packets being dropped.

Data VLAN The data VLAN carries the user data around the ring. Several data VLANs can share a common control VLAN.

Master node The master node controls the ring operation. It issues healthcheck messages at regular intervals from its primary port and monitors their arrival back at its secondary port - after they have circled the ring. Under normal operating conditions the master node's secondary port is always in the blocking state to all data VLAN traffic. This is to prevent data loops forming within the ring. This port however, operates in the forwarding state for the traffic on the control VLAN. Loops do not occur on the control VLAN because the control messages stop at the secondary port, having completed their path around the ring.

Transit nodes The transit nodes operate as conventional Ethernet bridges, but with the additional capability of running the EPSR protocol. This protocol requires the transit nodes to forward the healthcheck messages from the master node, and respond appropriately when a ring fault is detected. The fault condition procedure is explained in "Fault Detection and Recovery" on page 81.4.

Fault Detection and Recovery

EPSR uses the following methods to detect outages in a node or a link in the ring:

- Master node polling fault detection
- Transit node unsolicited fault detection

Master node polling

The master node issues healthcheck messages from its primary port as a means of checking the condition of the EPSR network ring. These messages are sent at regular periods, controlled by the hellotime parameter of the epsr command on page 82.3. A failover timer is set each time a healthcheck message leaves the master node's primary port. The timeout value for this timer is set by the failover parameter of the epsr command on page 82.3. If the failover timer expires before the transmitted healthcheck message is received by the master node's secondary port, the master node assumes that there is a fault in the ring, and implements its fault recovery procedures. Because this method relies on a timer expiry, its operation is inherently slower than the "transit node unsolicited detection method" described next.

Transit node unsolicited

Transit node unsolicited fault detection relies on transit nodes detecting faults at their interfaces, and immediately notifying master nodes about the break. When a transit node detects a connectivity loss, it sends a "links down" message over its good link. Because a link spans two nodes, both nodes send the "links down" message back to the master node. These nodes also change their state from "links up" to "links down," and change the state of the port connecting to the broken link, from "forwarding" to "blocking."

Fault Recovery

When the master node detects an outage in the ring by using its detection methods, it does the following:

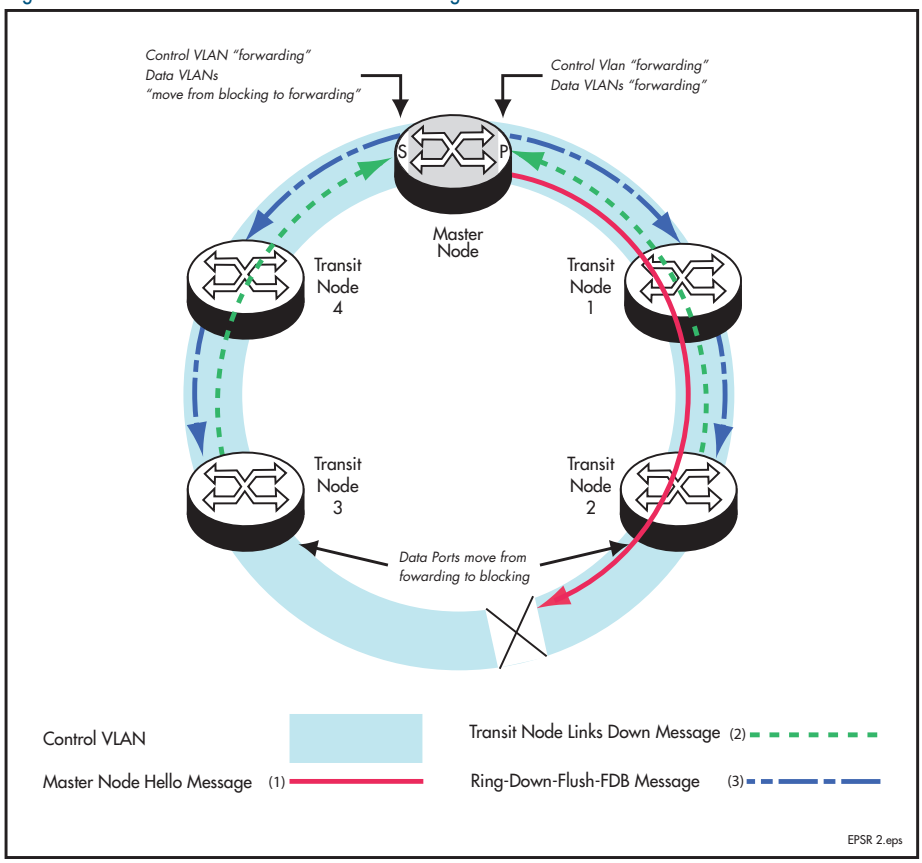
1. Declares the ring to be in a "failed" state.
2. Unblocks its secondary port to enable the data VLAN traffic to pass between its primary and secondary ports.
3. Flushes its own forwarding database (FDB) for (only) the two ring ports.
4. Sends an EPSR Ring-Down-Flush-FDB control message to all the transit nodes, via both its primary and secondary ports.

Transit nodes respond to the Ring-Down-Flush-FDB message by flushing their forward databases for each of their ring ports. As the data starts to flow in the ring's new configuration, each of the nodes (master and transit) re-learn their Layer 2 addresses. During this period, the master node continues to send health check messages over the control VLAN. This situation continues until the faulty link or node is repaired. For a multi-domain ring, this process occurs separately for each domain within the ring.

Note When VCStack is used with EPSR, the EPSR failovertime must be set to at least 5 seconds to avoid any broadcast storms during failover. Broadcast storms may occur if the switch cannot failover quickly enough before the EPSR failovertime expires. See the epsr command for further information about the EPSR failovertime. See the reboot rolling command for further information about VCStack failover.

The following figure shows the flow of control frames under fault conditions.

Figure 81-2: EPSR Fault Detection Messages



Restoring Normal Operation

Transit nodes

Once a fault in the ring or node has been rectified, the transit nodes that span the previously faulty link section detect that link connectivity has returned. They then move their appropriate ring port state, from Links-Down to Pre-Forwarding, and await the Ring-Up-Flush control message from the master node.

Once these transit nodes receive the Ring-Up-Flush message, they:

- flush their forward databases for both their ring ports.
- change the state of their ports from blocking to forwarding, which allows data to flow through their previously blocked ring ports.

Note

The transit nodes do not enter the forward state until they have received the Ring-Up-Flush message. This prevents the possibility of a loop condition occurring caused by the transit nodes moving into the forwarding state before the master node secondary port can return to the blocking state. During such a period, the ring would have no ports blocked.

Master node

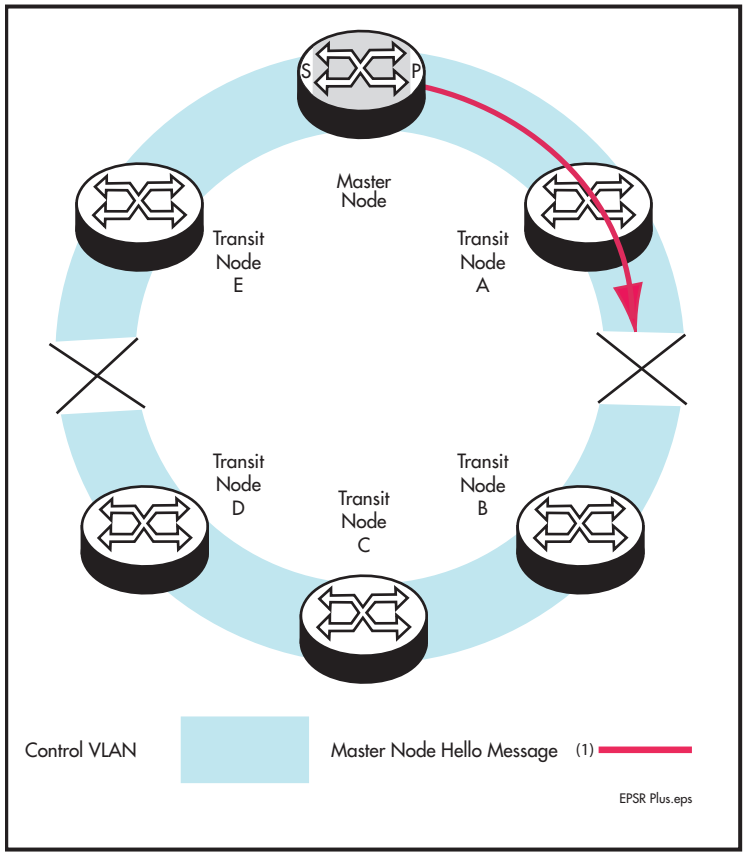
With the link restored, the healthcheck messages that are sent from the primary port of the master node now complete the loop and arrive at the master node's secondary port. The master node restores normal conditions as follows:

1. Declares the ring to be in a "complete" state.
2. Blocks its secondary port for data (non-control) traffic.
3. Flushes its forwarding database for its two ring ports.
4. Sends a Ring-Up-Flush-FDB message from its primary port, to all transit nodes.

Managing Rings with Two Breaks

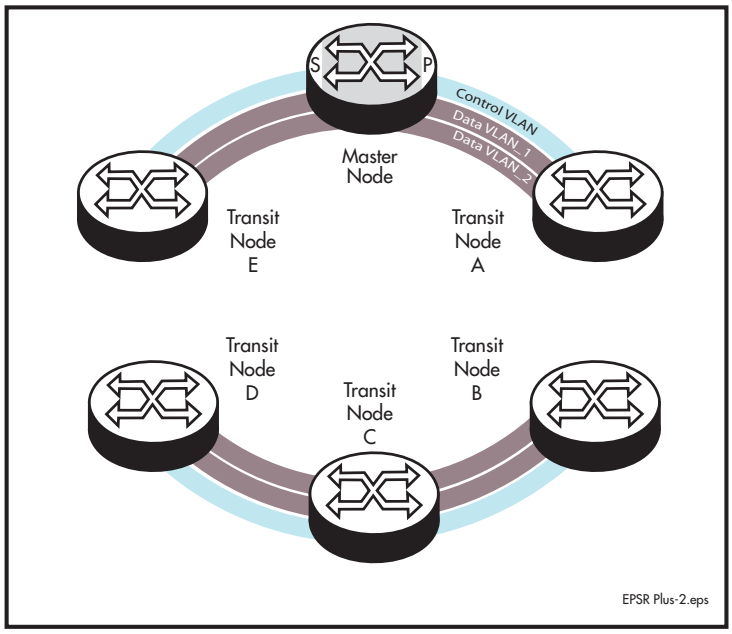
To restore a link with two breaks you need to run the EPSR Enhanced Recovery feature. Consider the network shown below:

Figure 81-3: EPSR Ring with Two Breaks



In this situation the ring will attempt to recover as previously described in "Fault Recovery" on page 81.4. This will result in the split-ring operation shown in Figure 81-4 on page 81.7.

Figure 81-4: EPSR Split Ring

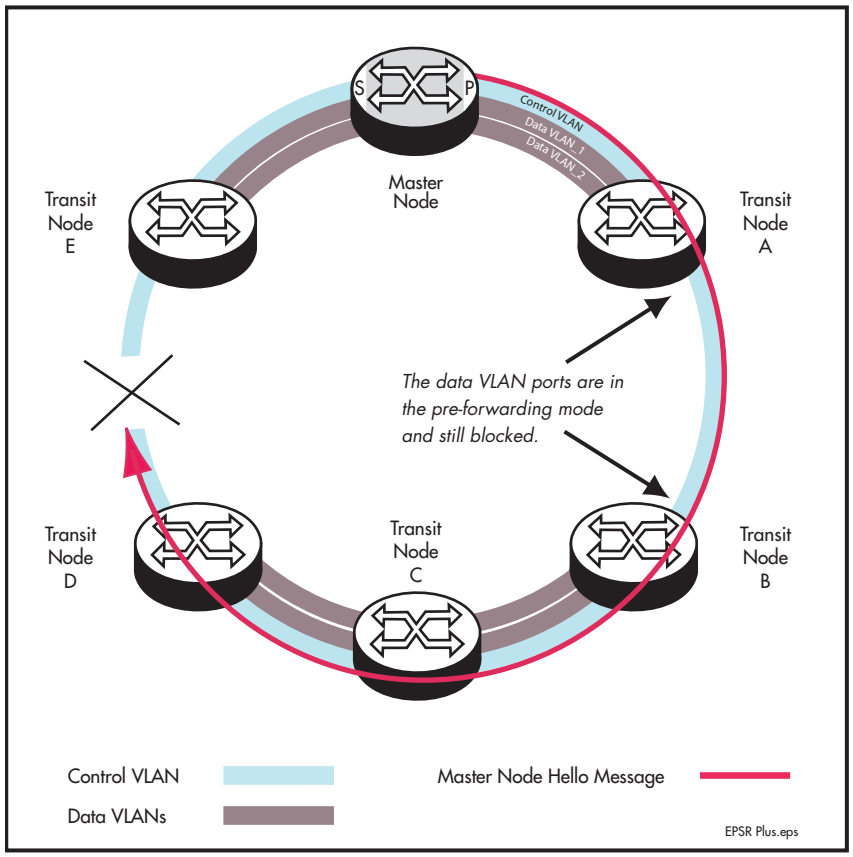


In this operational mode each portion of the ring operates as an independent link layer broadcast domain each containing the original data VLANs and control VLAN.

Recovery When One Break is Restored

Figure 81-5 on page 81.8 shows a ring with the link between nodes A and B restored. At this point the ring's behavior will depend on whether the epsr enhancedrecovery enable command on page 82.6 has been set.

Figure 81-5: EPSR Ring with One Link Restored



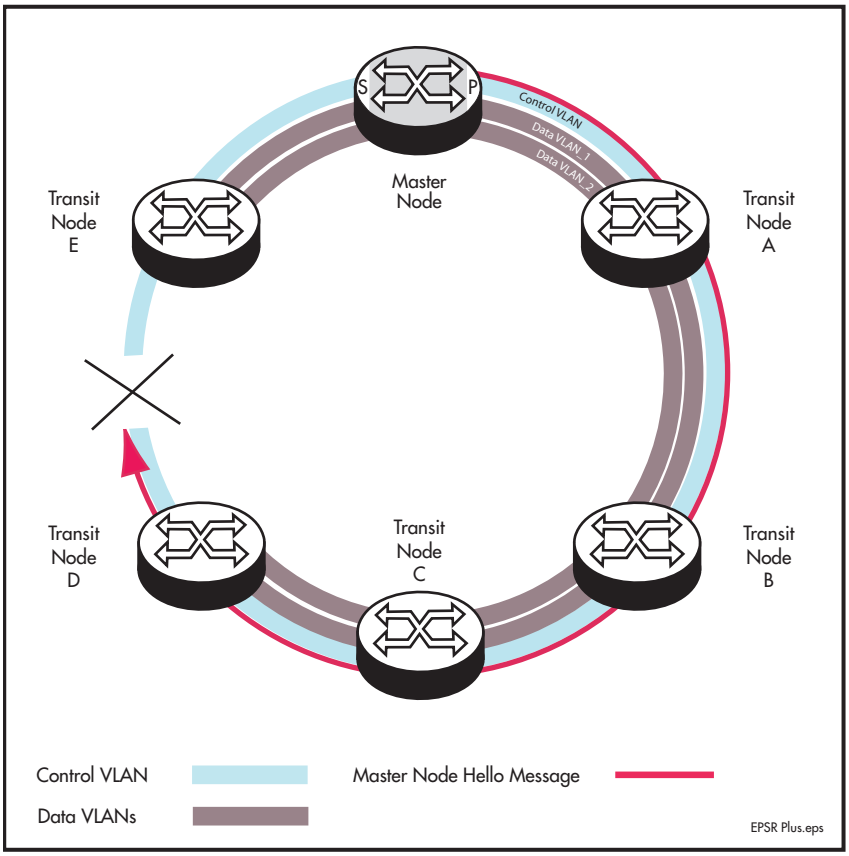
Enhanced Recovery Disabled

With the enhanced recovery feature disabled, the Hello messages will now reach the remaining ring break; however from a users perspective, the ring will remain as shown in the split state shown in Figure 81-5.

Enhanced Recovery Enabled

With the enhanced recovery feature enabled, switch nodes A and B are able to detect the restored link, and will place all their ring ports in the forwarding state. Although the ring will remain in the "failed" state because of the remaining break; communication between the nodes is restored. The network then operates as shown in Figure 81-6.

Figure 81-6: EPSR Operation in Partially Recovered State



Configuration Examples

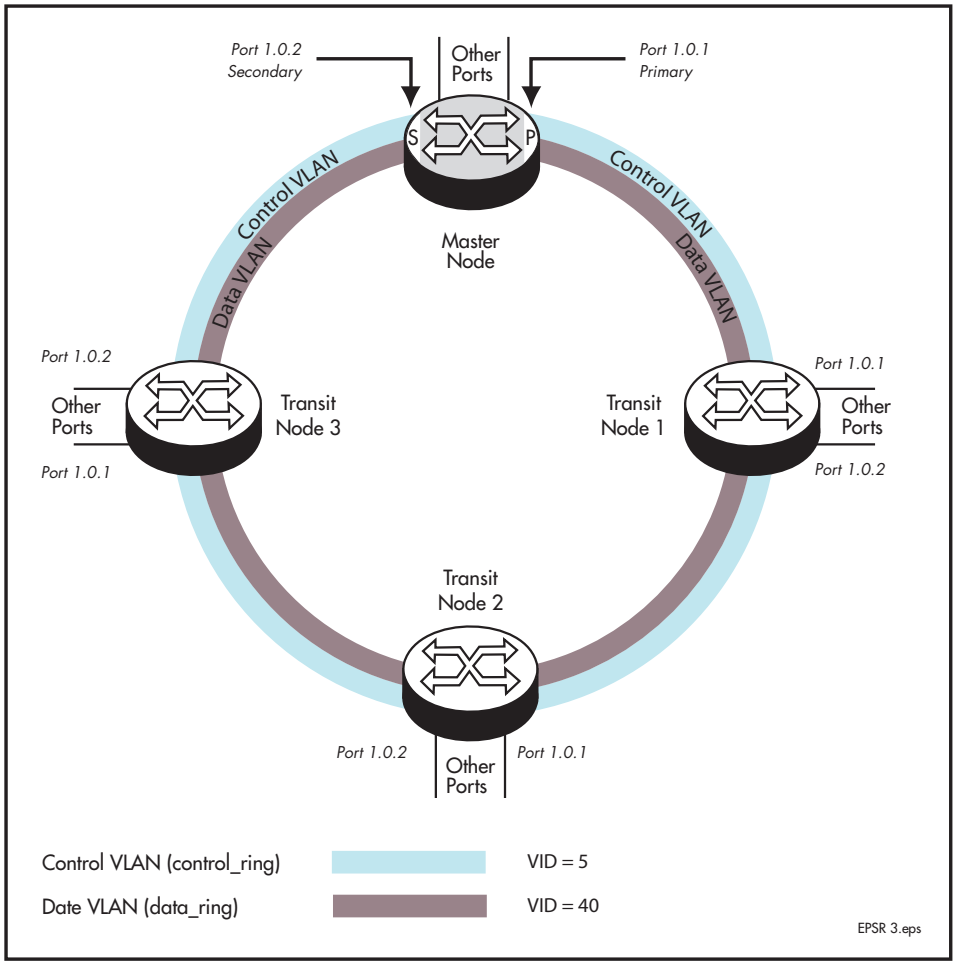
This section describes how to configure EPSR in following ways:

- Single Domain, Single Ring Network
- Single Ring, Dual Domain Network
- EPSR and Spanning Tree Operation

Single Domain, Single Ring Network

This example shows a simple single ring, single domain configuration with no connecting lobes.

Figure 81-7: EPSR single domain, single ring network



Configure the Master Node

Step 1: Create the control and data VLANs on the Master Node

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`vlan database`	Enter the VLAN Configuration mode.
`awplus(config-vlan)#`	
`vlan 5 name control_vlan state enable`	Enable VLAN 5 called `control_vlan` on the Master Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`vlan 40 name data_vlan state enable`	Enable VLAN 40 called `data_vlan` on the Master Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`exit`	Exit the VLAN Configuration mode and enter the Global Configuration mode.

Step 2: Add port1.0.1 to these VLANs

`awplus(config)#`	
`interface port1.0.1`	Specify the interface (`port1.0.1`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 5`	Enable VLAN 5 on this port.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if)#`	
`exit`	Exit the Interface mode and enter the Global Configuration mode.

Step 3: Add port1.0.2 to these VLANs

`awplus(config)#`	
`interface port1.0.2`	Specify the interface (`port1.0.2`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 5`	Enable VLAN 5 on this port.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if)#`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.

Step 4: Create the EPSR Instance called “blue” on the master node, make VLAN 5 the control VLAN and port 1.0.1 the primary port

`awplus(config)#`	
`epsr configuration`	Enter the EPSR Configuration mode.
`awplus(config-epsr)#`	
`epsr blue mode master controlvlan 5 primaryport port1.0.1`	Create an EPSR instance called `blue` on `vlan5`. Make `vlan5` the control VLAN. Make `port 1.0.1` the primary port. Make this node the master.

Step 5: Add a data VLAN to the EPSR Instance called “blue” on the Master Node

`awplus(config-epsr)#`	
`epsr blue datavlan 40`	On epsr instance called `blue` make `vlan40` the data VLAN.

Step 6: Enable the EPSR Instance called “blue” on the Master Node

`awplus(config-epsr)#`	
`epsr blue state enable`	Enable the EPSR instance named `blue`.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Now you can configure the transit nodes.

Step 7: Create the Control and Data VLANs on a Transit Node

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`vlan database`	Enter the VLAN Configuration mode.
`awplus(config-vlan)#`	
`vlan 5 name control_vlan state enable`	Enable VLAN 5 called `control_vlan` on the Transit Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`vlan 40 name data_vlan state enable`	Enable VLAN 40 called `data_vlan` on the Transit Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`exit`	Exit the VLAN Configuration mode and enter the Global Configuration mode.

Step 8: Add port1.0.1 to the VLANs

`awplus(config)#`	
`interface port1.0.1`	Specify the interface (`port1.0.1`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 5`	Enable VLAN 5 on this port.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if)#`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.

Step 9: Add port1.0.2 to the VLANs

`awplus(config)#`	
`interface port1.0.2`	Specify the interface (`port1.0.2`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 5`	Enable VLAN 5 on this port.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if)#`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.

Step 10: Create the EPSR Instance called “blue” on a transit node, make VLAN 5 the control VLAN

`awplus(config)#`	
`epsr configuration`	Enter the EPSR Configuration mode.
`awplus(config-epsr)#`	
`epsr blue mode transit controlvlan 5`	Create an EPSR instance called `blue` on `vlan5`. Make `vlan5` the control VLAN. Make this node a transit node.

Step 11: Add a data VLAN to the EPSR Instance called “blue” on the transit node

`awplus(config-epsr)#`	
`epsr blue datavlan 40`	On the EPSR instance called `blue` make `vlan40` the data VLAN.

Step 12: Enable the EPSR Instance called “blue” on the transit node

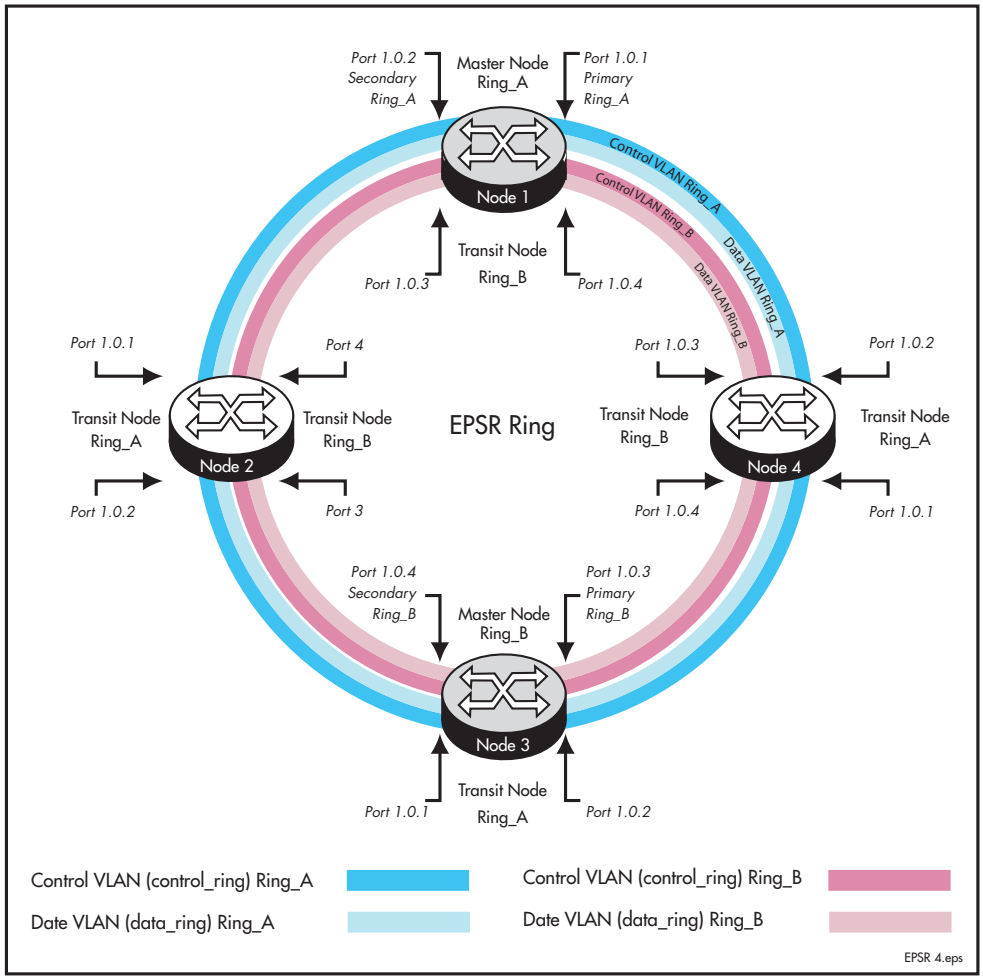
`awplus(config-epsr)#`	
`epsr blue state enable`	Enable the EPSR instance named `blue`.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Now you can use the same procedure to configure the remaining transit nodes.

Single Ring, Dual Domain Network

This example shows an EPSR configuration where two EPSR domains share the same physical ring. This configuration enables two sets of users to run totally separate Layer 2 networks. Better load distribution around the ring can be achieved by configuring different nodes to be the master for each ring.

Figure 81-8: EPSR single ring network, two domain network.

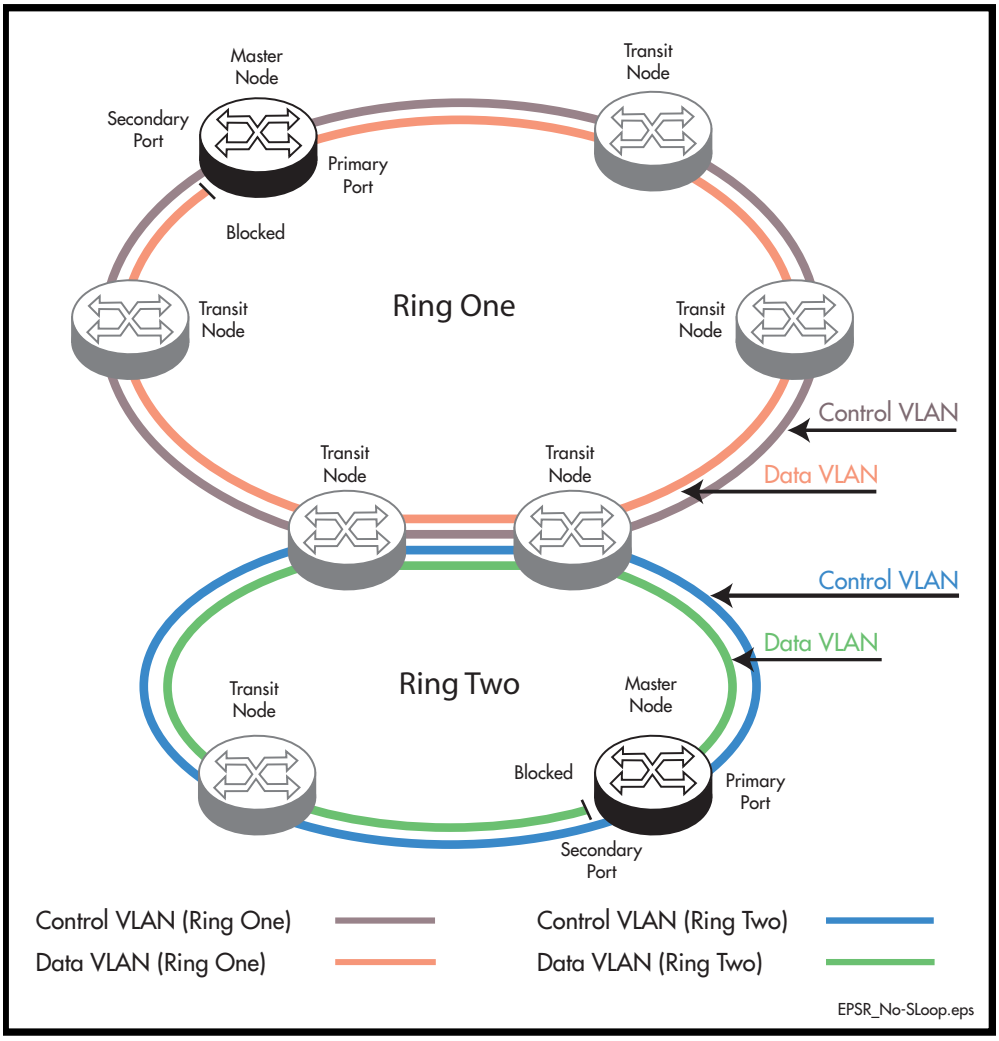


Interconnected Rings

This example shows an EPSR configuration where two rings share a common segment. This configuration will operate as two independent rings, providing that there is no data VLAN sharing between the two rings. If a break occurs in either ring then, each ring will implement its own independent recovery procedures. If a break occurs in the common segment, then each Master node will unblock its secondary port using the normal fault recovery procedure.

Where data VLANS are shared between the rings a fault condition know as “SuperLoop” can occur. The next section deals with superloops and how to manage them.

Figure 81-9: Interconnected EPSR Rings with No Data VLAN Sharing



Superloop Protection

Careful attention must be paid when creating EPSR networks with interconnecting links, to avoid an error condition known as superloops. This sections explains what superloops are and how to prevent them.

What is a an EPSR Superloop?

An EPSR superloop is a data loop whose path traverses more than a single EPSR ring. This fault condition usually occurs when there is a break in a physical segment that is shared by the two rings. For a superloop condition to occur, the two physical rings must share some of their data VLANS. Figure 81-10 on page 81.17shows an EPSR ring with a superloop condition caused by a break in the common ring segment. Figure 81-11 on page 81.18 shows the Superloop data path ring caused by the broken common ring segment. The superloop condition occurs because both rings detect the ring segment break and as a result both master nodes unblock their secondary ports.

Figure 81-10: Interconnected EPSR Rings with Data VLAN Sharing

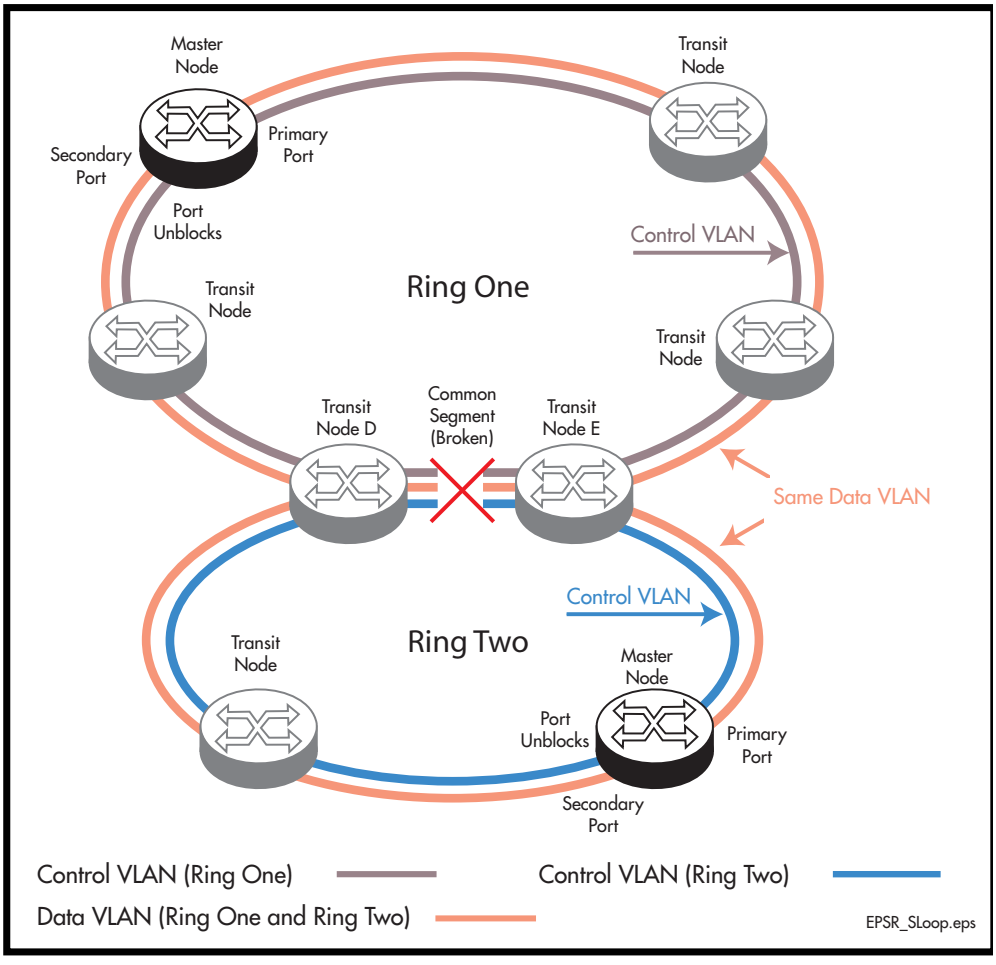


Figure 81-11: EPSR Superloop data path caused by a broken common ring segment

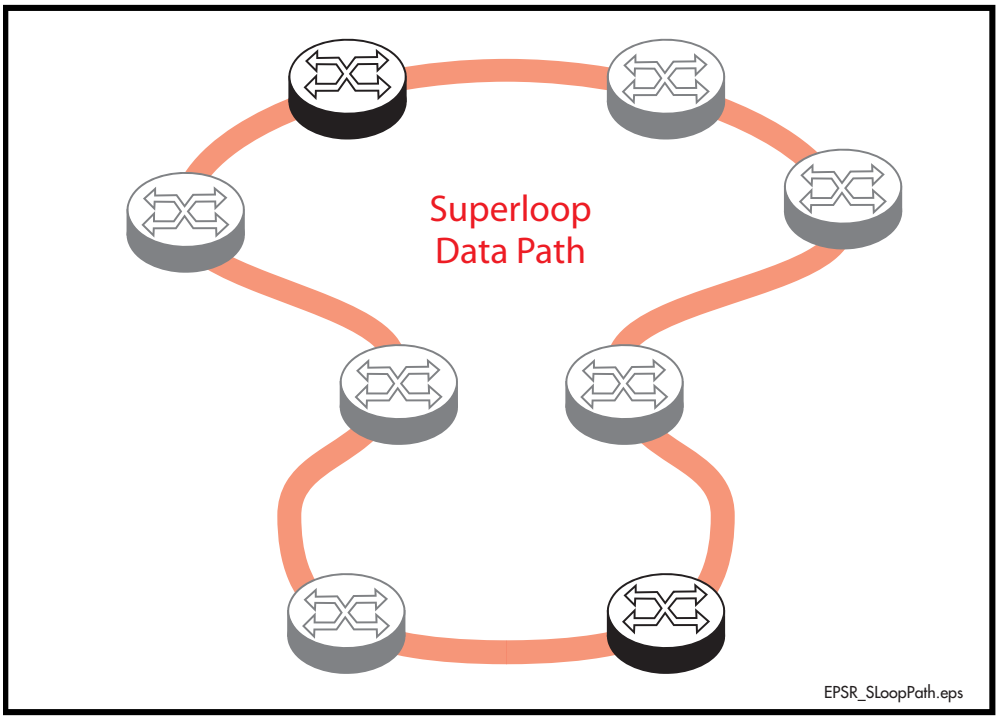


EPSR Superloop Prevention

Alliedware Plus version 5.4.2 onwards contains mechanisms to prevent superloops forming. The Superloop prevention facility enables rings to be assigned priority level between 0 and 127, with 1 representing the lowest priority and 127 the highest. Level 0 (the default setting) applies the functionality of no Superloop prevention. Enabling superloop prevention changes the way the EPSR nodes respond under fault conditions.

Superloop prevention is enabled for an EPSR ring instance by setting the epsr priority command on page 82.9. Setting a priority value greater than 0 applies superloop prevention to that particular instance. How the superloop function is applied will depend on the role of the node within the ring, i.e. whether it is a master node or a transit node, and its physical location within the ring. Here is how the functions of Superloop prevention modify the nodal behavior for a particular ring instance:

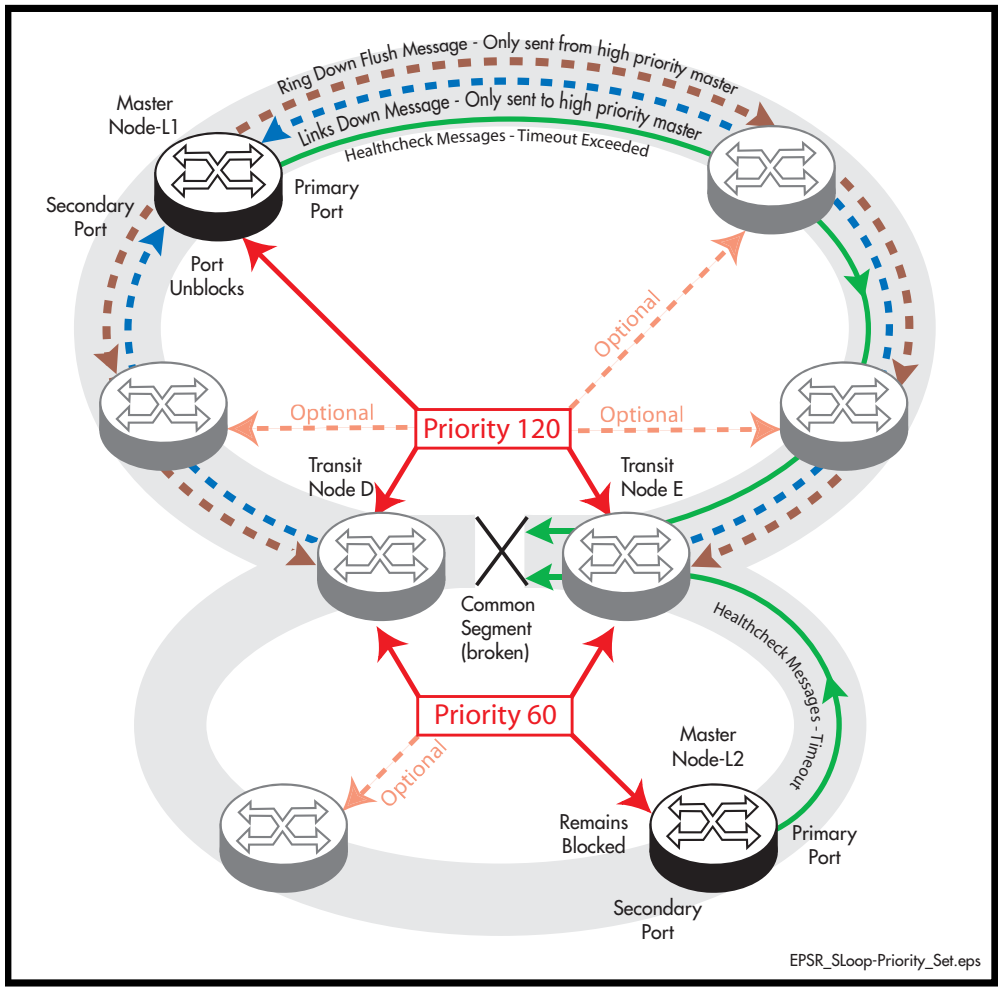
- A master node with its epsr priority set to zero will consider the superloop function to be turned off.
- A master node with its epsr priority set within the range 1-127 will consider the superloop function to be enabled, and will change its behavior in the following ways.
  - « It will not unblock its secondary port following the expiry of the Master Node Hello message timer. However, a ring-down-flush message will still be sent.
  - « It will only unblock its secondary port when it receives a Links Down message from a transit node.
- A transit node that is not connect to a shared link will be unaffected by having its epsr priority set for any of its instances.

- A transit node that is connected to a shared link will change its behavior in the following ways:
  - « It will compare its priority settings applied to each of the instances sharing the common link. So for the network of Figure 81-10 on page 81.17 Transit Node D will compare the priority setting for Ring One, with the priority setting for Ring Two.

    If the shared link fails, the transit node will only issue a Transit Node Links Down message on the ring that is configured with the highest priority.

The result of these behavior changes is that when the shared link fails, only the master node located on the higher priority ring will unblock its secondary port; because this is the only the master node that will receive the Transit Node Links Down message. Note also that the master node will receive these messages from the transit nodes at either end of the broken shared link (Nodes D and E). This concept is illustrated in

Figure 81-12: EPSR behavior under fault conditions with Superloop enabled



For this process to work requires certain configuration rules to be obeyed.

Configuration Rules for Superloop Protected EPSR Rings

The following configuration rules are advised when configuring EPSR rings that share one or more common segments.

- Allocate a priority order to each of the interconnected rings, with 127 being the highest priority and 1 the lowest.
- A higher priority ring can have its master node located in any position; although, where possible, avoid connecting a common segment to the secondary port of a master node.
- Do not locate the master node on a segment that is shared with a higher priority ring, but you "can" locate it on a common segment that is shared with a lower priority ring. In this situation however, the port that connects to the common segment must be configured as the primary port.

  For example, in Figure 81-12, the upper portion of Node D could be configured as a Master Node of the upper ring (having a priority of 120), but its lower portion must be configured as a Transit Node (having the lower priority of 60).
- On the transit nodes that connect to shared links, allocate the ring's priority to the ports that connect to each ring. Note that both of these nodes "must" be set to the same priority value.

Note

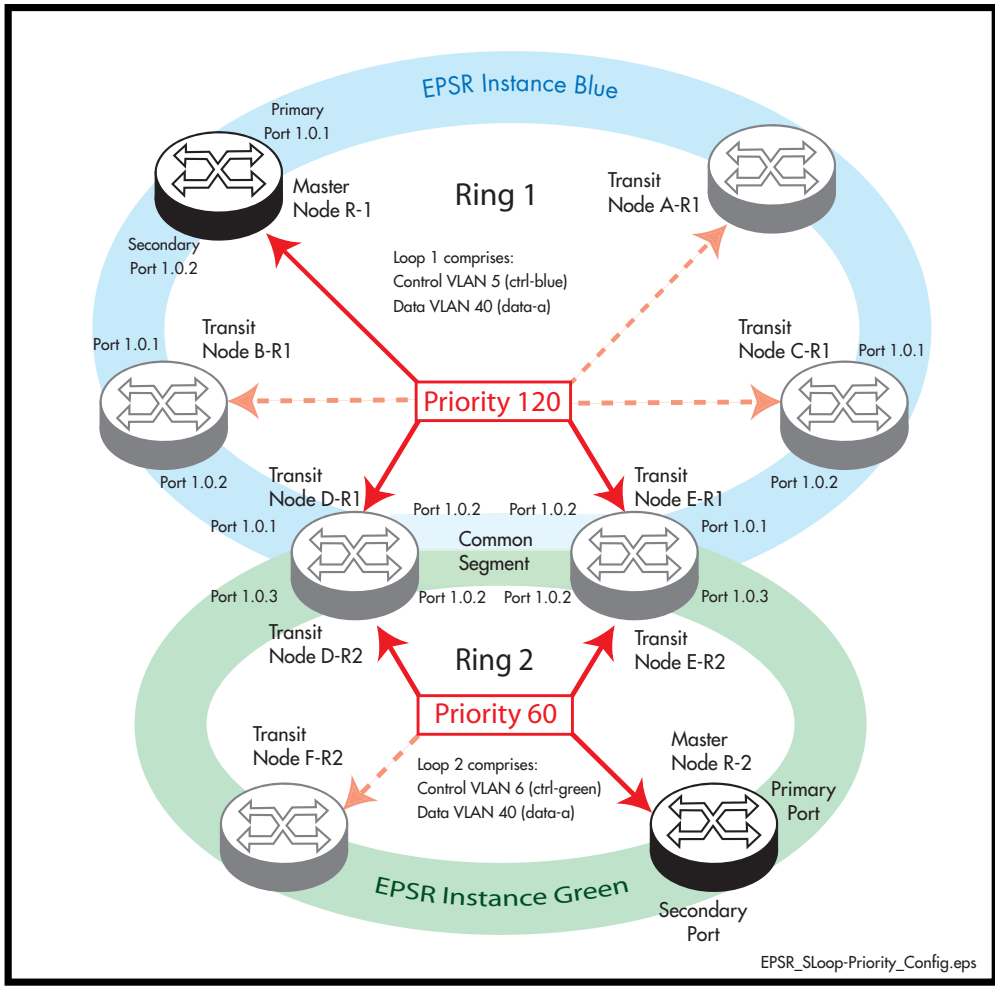
For good practice, we advise that you set all nodes within a ring to the priority assigned to that ring. So, for the network of Figure 81-12 each of the nodes that form part of the upper ring would be configured with a priority of 120, and each of the nodes that form the lower ring would all be configured with a priority of 60.

Configuring a Basic Superloop Protected Two Ring EPSR Network

Configuration Example

This section shows how to configure a basic EPSR network such as that shown in Figure 81-13 below

Figure 81-13: EPSR Two Shared Ring Example



The configuration suggested comprises the following basic steps:

- “On Ring 1- Configure the Master Node R-1” on page 81.22
- “On Ring 1 - Configure the Transit Nodes A to C” on page 81.24
- “On Ring 2 - Configure the Master Node R-2” on page 81.26
- “On Rings 1 and 2 - Configure the Transit Nodes D and E” on page 81.28
- “On Ring 2 - Configure the Transit Node F” on page 81.34

On Ring 1- Configure the Master Node R-1

Step 1: Create the control and data VLANs (Configure on the Master Node R-1)

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`vlan database`	Enter the VLAN Configuration mode.
`awplus(config-vlan)#`	
`vlan 5 name ctrl-blue state enable`	Enable VLAN 5 called ctrl-blue on the Master Node R-1. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`vlan 40 name data-a state enable`	Enable VLAN 40 called data-a on the Master Node R-1. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`exit`	Exit the VLAN Configuration mode and enter the Global Configuration mode.

Step 2: Add the control VLAN (ctrl-blue) to the Ring Ports

`awplus(config)#`	
`interface port1.0.1,port1.0.2`	Specify the two ring ports (`port1.0.1 and port1.0.2`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of these ports to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 5`	Enable VLAN 5 on these ports.
`awplus#`	
`switchport trunk native vlan none`	Remove the native VLAN from these ring ports.

Step 3: Create the EPSR Instance called “blue”, make VLAN 5 the control VLAN and port 1.0.1 the primary port (Configure on the Master Node R-1)

`awplus(config)#`	
`epsr configuration`	Enter the EPSR Configuration mode.
`awplus(config-epsr)#`	
`epsr blue mode master controlvlan 5 primaryport port1.0.1`	Create an EPSR instance called `blue` on `vlan 5`. Make `vlan 5` the control VLAN. Make `port 1.0.1` the primary port. Make this node the master.

Step 4: Add a data VLAN to the EPSR Instance called “blue” (Configure on the Master Node R-1)

`awplus(config-epsr)#`	
`epsr blue datavlan 40`	On epsr instance called blue data-a the data VLAN.

Step 5: Assign a priority to the ring instance (Configure on the Master Node R-1)

`awplus(config-epsr)#`	
`epsr blue priority 120`	Set the ring instance priority to the value selected for the ring. The priority value selected is 120.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 6: Enable the EPSR Instance called “blue” (Configure on the Master Node R-1)

`awplus(config-epsr)#`	
`epsr blue state enable`	Enable the EPSR instance named `blue`.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 7: Add port1.0.1 to these VLANs (Configure on the Master Node R-1)

`awplus(config)#`	
`interface port1.0.1,port1.0.2`	Specify the EPSR ring ports (`port1.0.1 and 1.0.2`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if)#`	
`exit`	Exit the Interface mode and enter the Global Configuration mode.

On Ring 1 - Configure the Transit Nodes A to C

Step 1: Create the control and data VLANs (on Transit Nodes A to C)

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`vlan database`	Enter the VLAN Configuration mode.
`awplus(config-vlan)#`	
`vlan 5 name ctrl-blue state enable`	Enable VLAN 5 called `ctrl-blue` on the Transit Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`vlan 40 name data-a state enable`	Enable VLAN 40 called `data-a` on the Transit Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`exit`	Exit the VLAN Configuration mode and enter the Global Configuration mode.

Step 2: Add the EPSR control vlan (ctrl-blue) to EPSR ring ports

`awplus(config)#`	
`interface port1.0.1,port1.0.2`	Specify the two ring ports (`port1.0.1 and port1.0.2`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 5`	Enable VLAN 5 on these ports.
`awplus#`	
`switchport trunk native vlan none`	Remove the native VLAN from the ring ports.

Step 3: Create the EPSR Instance called “blue”, make VLAN 5 the control VLAN (on Transit Nodes A to C)

`awplus(config)#`	
`epsr configuration`	Enter the EPSR Configuration mode.
`awplus(config-epsr)#`	
`epsr blue mode transit controlvlan 5`	Create an EPSR instance called `blue` on `vlan 5`. Make `vlan 5` the control VLAN. Make this node a transit node.

Step 4: Add a data VLAN to the EPSR Instance called “blue” (on Transit Nodes A to C)

`awplus(config-epsr)#`	
`epsr blue datavlan 40`	On the EPSR instance called `blue` make `vlan 40` the data VLAN.

Step 5: Assign a priority to the ring instance (on Transit Nodes A to C)

This step is mandatory on transit nodes that connect to a common segment, and good practice on other transit nodes.

`awplus(config-epsr)#`	
`epsr blue priority 120`	Set the ring instance priority to the priority selected for the ring 120.

Step 6: Enable the EPSR Instance called “blue” (on Transit Nodes A to C)

`awplus(config-epsr)#`	
`epsr blue state enable`	Enable the EPSR instance named `blue`.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 7: Add the physical port 1.0.1 to VLAN 40 (on Transit Nodes A to C)

`awplus(config)#`	
`interface port1.0.1,port1.0.2`	Specify the physical ring ports (`ports1.0.1` and ports 1.0.2) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if)#`	
`exit`	Exit the Interface mode and enter the Global Configuration mode.

On Ring 2 - Configure the Master Node R-2

Step 1: Create the control and data VLANs (Configure on the Master Node R-2)

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`vlan database`	Enter the VLAN Configuration mode.
`awplus(config-vlan)#`	
`vlan 6 name ctrl-green state enable`	Enable vlan 6 called ctrl-green on the Master Node R-2. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`vlan 40 name data-a state enable`	Enable VLAN 40 called data-a on the Master Node R-2. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`exit`	Exit the VLAN Configuration mode and enter the Global Configuration mode.

Step 2: Add the control VLAN (ctrl-green) to the Ring Ports

`awplus(config)#`	
`interface port1.0.1,port1.0.2`	Specify the ports (`port1.0.1 and port1.0.2`) that you are configuring, and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of these ports to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 6`	Enable vlan 6 on these ports.
`awplus(config-if)#`	
`switchport trunk native vlan none`	Remove the native VLAN from these ring ports.

Step 3: Create the EPSR Instance called “green”, make vlan 6 the control VLAN and port1.0.1 the primary port (Configure on the Master Node R-2)

`awplus(config)#`	
`epsr configuration`	Enter the EPSR Configuration mode.
`awplus(config-epsr)#`	
`epsr green mode master controlvlan 6 primaryport port1.0.1`	Create an EPSR instance called `ctrl-green` on `vlan 6`. Make `vlan 6` the control VLAN. Make `port 1.0.1` the primary port. Make this node the master.

Step 4: Add a data VLAN to the EPSR Instance called “green” (Configure on the Master Node R-2)

`awplus(config-epsr)#`	
`epsr green datavlan 40`	On epsr instance called green make `vlan 40` the data VLAN.

Step 5: Assign a priority to the ring instance (Configure on the Master Node R-2)

This step is mandatory on transit nodes that connect to a common segment, and good practice on other transit nodes.

`awplus(config-epsr)#`	
`epsr green priority 60`	Set the ring instance priority to the value selected for the ring. The priority value selected is 60.

Step 6: Enable the EPSR Instance called “green” (Configure on the Master Node R-2)

`awplus(config-epsr)#`	
`epsr green state enable`	Enable the EPSR instance named green.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 7: Add ports 1.0.1 and 1.0.2 to these VLANs (Configure on the Master Node R-2)

`awplus(config)#`	
`interface port1.0.1,port1.0.2`	Specify the ports (`port1.0.1 and port1.0.2`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of these ports to Trunk mode.
`awplus(config-if)#`	
`exit`	Exit the Interface mode and enter the Global Configuration mode.

On Rings 1 and 2 - Configure the Transit Nodes D and E

Step 1: Create the control and data VLANs (on Transit Nodes D and E)

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`vlan database`	Enter the VLAN Configuration mode.
`awplus(config-vlan)#`	
`vlan 5 name ctrl-blue state enable`	Enable VLAN 5 called `ctrl-blue` on the Transit Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`vlan 40 name data-a state enable`	Enable VLAN 40 called `data-a` on the Transit Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`vlan 6 name ctrl-green state enable`	Enable VLAN 6 called `ctrl-green` on the Transit Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`exit`	Exit the VLAN Configuration mode and enter the Global Configuration mode.

Step 2: Add physical port1.0.1 to these VLANs (on Transit Nodes D and E)

`awplus(config)#`	
`interface port1.0.1`	Specify the physical `interface (port1.0.1)` that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 5`	Enable VLAN 5 on this port.
`awplus(config-if)#`	
`switchport trunk native vlan none`	Remove the native VLAN.
`awplus(config-if)#`	
`exit`	Exit the Interface mode and enter the Global Configuration mode.

Step 3: Add physical port port1.0.2 to these VLANs (on Transit Nodes D and E)

`awplus(config)#`	
`interface port1.0.2`	Specify the physical `interface (port1.0.2)` that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 5`	Enable VLAN 5 (ctrl-blue) on this port.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 6`	Enable VLAN 6 (ctrl-green) on this port.
`awplus(config-if)#`	
`switchport trunk native vlan none`	Remove the native VLAN.
`awplus(config-if)#`	
`exit`	Exit the Interface mode and enter the Global Configuration mode.

Step 4: Add physical port1.0.3 to these VLANs (on Transit Nodes D and E)

`awplus(config)#`	
`interface port1.0.3`	Specify the physical `interface (port1.0.3)` that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.

`awplus(config-if)#`	
`switchport trunk allowed vlan add 6`	Enable VLAN 6 on this port.
`awplus(config-if)#`	
`switchport trunk native vlan none`	Remove the native VLAN.
`awplus(config-if)#`	
`exit`	Exit the Interface mode and enter the Global Configuration mode.

Step 5: Create the EPSR Instance called “blue” on a transit node, make VLAN 5 the control VLAN (on Transit Nodes D and E)

`awplus(config)#`	
`epsr configuration`	Enter the EPSR Configuration mode.
`awplus(config-epsr)#`	
`epsr blue mode transit controlvlan 5`	Create an EPSR instance called `blue` on `vlan 5`. Make `vlan 5` the control VLAN. Make this node a transit node.

Step 6: Add a data VLAN to the EPSR Instance called “blue” (on Transit Nodes D and E)

`awplus(config-epsr)#`	
`epsr blue datavlan 40`	On the EPSR instance called `blue` make `vlan 40` the data VLAN.

Step 7: Assign a priority to the ring instance (on Transit Nodes D and E)

This step is mandatory on transit nodes that connect to a common segment, and good practice on other transit nodes.

`awplus(config-epsr)#`	
`epsr blue priority 120`	Set the ring instance priority to 120 - the value selected for the ring.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 8: Enable the EPSR Instance called “blue” (on Transit Nodes D and E)

`awplus(config-epsr)#`	
`epsr blue state enable`	Enable the EPSR instance named `blue`.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 9: Create the EPSR Instance called “green” on a transit node, make VLAN 6 the control VLAN (on Transit Nodes D and E)

`awplus(config-epsr)#`	
`epsr green mode transit controlvlan 6`	Create an EPSR instance called `green` on `vlan 6`. Make `vlan 6` the control VLAN. Make this node a transit node.

Step 10: Add a data VLAN to the EPSR Instance called "green" (on Transit Nodes D and E)

`awplus(config-epsr)#`	
`epsr green datavlan 40`	On the EPSR instance called `green` make `vlan 40` the data VLAN.

Step 11: Assign a priority to the ring instances (on Transit Nodes D and E)

This step is mandatory on transit nodes that connect to a common segment, and good practice on other transit nodes.

`awplus(config-epsr)#`	
`epsr green priority 60`	Set the ring instance priority to 60 - this being the priority selected for the ring.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 12: Enable the EPSR Instance called "green" (on Transit Nodes D and E)

`awplus(config-epsr)#`	
`epsr green state enable`	Enable the EPSR instance named `green`.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 13: Add the physical port 1.0.1 to these VLANs (on Transit Nodes D and E)

`awplus(config)#`	
`interface port1.0.1`	Specify the physical interface (`port1.0.1`) that you are configuring, and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if#`	
`switchport trunk native vlan none`	Remove the native VLAN
`awplus(config-if)#`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.

Step 14: Add the physical port1.0.2to these VLANs (on Transit Nodes D and E)

`awplus(config)#`	
`interface port1.0.2`	Specify the physical interface (`port1.0.2`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if#`	
`switchport trunk native vlan none`	Remove the native VLAN
`awplus(config-if)#`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.

Step 15: Add the physical port1.03to these VLANs (on Transit Nodes D and E)

`awplus(config)#`	
`interface port1.0.3`	Specify the physical interface (`port1.0.3`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if#`	
`switchport trunk native vlan none`	Remove the native VLAN
`awplus(config-if)#`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.

On Ring 2 - Configure the Transit Node F

Step 1: Create the control and data VLANs (on Transit Node F)

`awplus#`	
`configure terminal`	Enter the Global Configuration mode.
`awplus(config)#`	
`vlan database`	Enter the VLAN Configuration mode.
`awplus(config-vlan)#`	
`vlan 6 name ctrl-green state enable`	Enable VLAN 6 called `ctrl-green` on the Transit Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`vlan 40 name data-a state enable`	Enable VLAN 40 called `data-a` on the Transit Node. Specifying the enable state allows forwarding of frames on the VLAN-aware node.
`awplus(config-vlan)#`	
`exit`	Exit the VLAN Configuration mode and enter the Global Configuration mode.

Step 2: Create the EPSR Instance called “green” on a transit node, make VLAN 6 the control VLAN (on Transit Node F)

`awplus(config)#`	
`epsr configuration`	Enter the EPSR Configuration mode.
`awplus(config-epsr)#`	
`epsr green mode transit controlvlan 6`	Create an EPSR instance called `green` on `vlan 6`. Make `vlan 6` the control VLAN. Make this node a transit node.

Step 3: Add a data VLAN to the EPSR Instance called “green” (on Transit Node F)

`awplus(config-epsr)#`	
`epsr green datavlan 40`	On the EPSR instance called `green` make `vlan 40` the data VLAN.

Step 4: Enable the EPSR Instance called “green” (on Transit Node F)

`awplus(config-epsr)#`	
`epsr green state enable`	Enable the EPSR instance named `green`.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 5: Assign a priority to the ring instance (on Transit Node F)

This step is mandatory on transit nodes that connect to a common segment, and good practice on other transit nodes.

`awplus(config-epsr)#`	
`epsr green priority 120`	Set the ring instance priority to the priority selected for the ring 120.
`awplus(config-epsr)#`	
`exit`	Exit the EPSR Configuration mode.

Step 6: Add the physical port port1.0.1 to VLANs 6 and 40 (on Transit Node F)

`awplus(config)#`	
`interface port1.0.1`	Specify the physical interface (`port1.0.1`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 6`	Enable VLAN 6 on this port.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if)#`	
`exit`	Exit the Interface mode and enter the Global Configuration mode.

Step 7: Add the physical port port1.0.2 to VLANs 6 and 40 (on Transit Node F)

`awplus(config)#`	
`interface port1.0.2`	Specify the interface (`port1.0.2`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport mode trunk`	Set the switching characteristics of this port to Trunk mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 6`	Enable VLAN 6 on this port.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 40`	Enable VLAN 40 on this port.
`awplus(config-if)#`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.

Sample Show Output

For the above network configuration, running the command show epsr on node R1 will display the following output when operating normally. Note the blocked state of its secondary port.

Figure 81-14: Output from the **show epsr** command run on Master Node R1 - with Ring 1 - EPSR Instance blue operating normally

```
 EPSR Information
-----------------------------------------------------------------
 Name .....................blue
 Mode .....................Master
 Status ...................Enabled
 State ....................Complete
 Control Vlan .............5
 Data VLAN(s) .............40
 Interface Mode ...........Ports Only
 Primary Port .............port1.0.1
   Status .................Forwarding
   Is On Common Segment ...No
   Blocking Control .......Physical
 Secondary Port ...........port1.0.2
   Status .................Blocked
   Is On Common Segment ...No
   Blocking Control .......Physical
 Hello Time ...............1 s
 Failover Time ............2 s
 Ring Flap Time ...........0 s
 Trap .....................Enabled
 Enhanced Recovery ........Disabled
 Priority .................120
-----------------------------------------------------------------
```

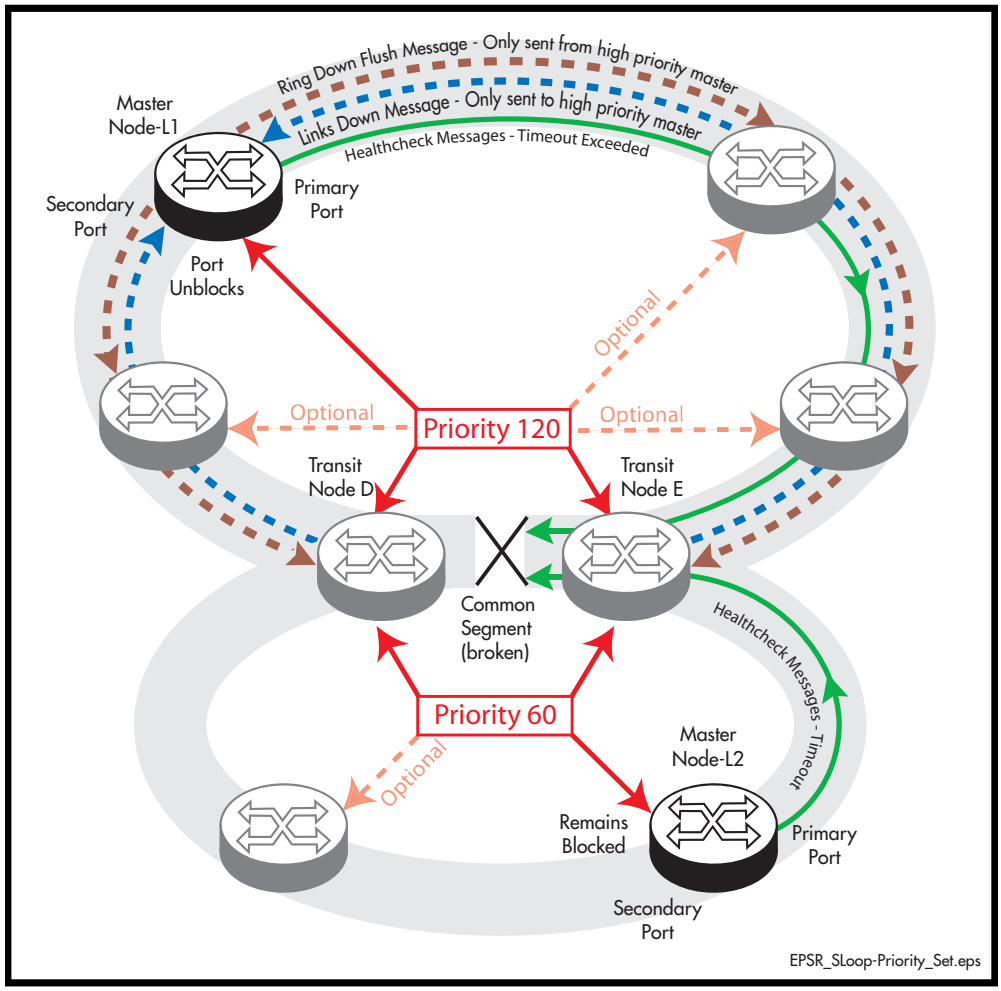
If a fault occurs somewhere within the blue network ring the Master Node-R1 would respond by placing its secondary port into the forwarding state. Figure Figure 81-15 displays its resultant state. Note that the state of its secondary port has now moved from Blocked, Forwarding.

Figure 81-15: Output from the **show epsr** command run on Master Node R2, where a break exists within the Ring 1 - EPSR instance blue.

```
 EPSR Information
-----------------------------------------------------------------
 Name .....................blue
 Mode .....................Master
 Status ...................Enabled
 State ....................Failed
 Control Vlan .............6
 Data VLAN(s) .............40
 Interface Mode ...........Ports Only
 Primary Port .............port1.0.1
   Status .................Forwarding
   Is On Common Segment ...No
   Blocking Control .......Physical
 Secondary Port ...........port1.0.2
   Status .................Forwarding
   Is On Common Segment ...No
   Blocking Control .......Physical
 Hello Time ...............1 s
 Failover Time ............2 s
 Ring Flap Time ...........0 s
 Trap .....................Enabled
 Enhanced Recovery ........Disabled
 Priority .................60
-----------------------------------------------------------------
```

If a fault occurs in the common segment of the ring then the Master Node-R2 being on the lower priority ring would detect a timeout of its transmitted Healthcheck Message. It would also detect the absence of the expected Ring Down Flush message, see Figure 81-16. The Master node then assumes that there is a break somewhere in the Common Segment, and will display the status shown in Figure 81-17.

Figure 81-16: EPSR behavior with a faulty common segment and Superloop enabled



Note that the secondary port on Master Node-L2 remains in the blocked state; its state now appears in show output as being as blocked (for superloop prevention), See Figure 81-17.

The Master-L1 on the blue ring will also detect a timeout in the healthcheck message, but because ring 1 has the higher priority (of 120), it will receive a Links Down message from each of the Transit Nodes (D and E) that connect to the common segment. As a result, the state of the Master Node will be as shown in Figure Figure 81-17; note particularly the change in its Secondary Port status.

Figure 81-17: Output from the **show epsr** command run on Master Node L2 (green)

```
 EPSR Information
-----------------------------------------------------------------
 Name .....................green
 Mode .....................Master
 Status ...................Enabled
 State ....................Failed
 Control Vlan .............6
 Data VLAN(s) .............40
 Interface Mode ...........Ports Only
 Primary Port .............port1.0.1
   Status .................Forwarding
   Is On Common Segment ...No
   Blocking Control .......Physical
 Secondary Port ...........port1.0.2
   Status .................Blocked (for superloop prevention)
   Is On Common Segment ...No
   Blocking Control .......Physical
 Hello Time ...............1 s
 Failover Time ............2 s
 Ring Flap Time ...........0 s
 Trap .....................Enabled
 Enhanced Recovery ........Disabled
 Priority .................60
-----------------------------------------------------------------
```

Adding a new data VLAN to a functioning superloop topology

This example shows how to add another data VLAN called data-b to the superloop topology. We recommend that you apply the configuration steps in the order shown.

1. Add VLAN to the common segment (for both instances)
2. Add VLAN to blue master
3. Add VLAN to other blue transits
4. Add VLAN to green master
5. Add VLAN to other green transits

On Ring 1 EPSR Instance Blue - Configure each of the Transit Nodes that Connect to the Common Segment

Select one of the transit nodes that connects to the common segment, and carry out the following steps:

Step 1: Add VLAN 50 to the VLAN database and set its state to enable

`awplus#`	
`configure terminal`	Enter terminal config mode
`awplus(config)#`	
`vlan database`	Enter the EPSR Configuration mode.
`awplus(config-epsr)#`	
`vlan 50 name data-b enable`	Create vlan 50, name it data-b and enable it.

Step 2: Add the VLAN 50 to the EPSR Instances called “blue”and “green” on the transit nodes

`awplus(config)#`	
`epsr configuration`	Enter the EPSR Configuration mode.
`awplus(config-epsr)#`	
`epsr blue datavlan 50`	On the EPSR instance called `blue` add `vlan 50` as a data VLAN.
`awplus(config-epsr)#`	
`epsr green datavlan 50`	On the EPSR instance called `green` add `vlan 50` as a data VLAN.

Step 3: Add the common physical port (port1.0.2 in this example) to VLAN 50

`awplus(config)#`	
`interface port1.0.2`	Specify the physical interface (`port1.0.2`) that you are configuring and enter the Interface Configuration mode.

awplus(config-if)#	
switchport trunk allowed vlan add 50	Enable VLAN 50 on this port.
awplus(config-if)#	
exit	Exit the Interface mode and enter the Global Configuration mode.

Step 4: Add physical port1.0.1 to VLAN 50

awplus(config)#	
interface port1.0.1	Specify the interface (port1.0.1) that you are configuring and enter the Interface Configuration mode.
awplus(config-if)#	
switchport trunk allowed vlan add 50	Enable VLAN 50 on this port.
awplus(config-if)#	
exit	Exit the Interface Configuration mode and enter the Global Configuration mode.

Step 5: Add physical port1.0.3 to VLAN 50

`awplus(config)#`	
`interface port1.0.3`	Specify the interface (`port1.0.3`) that you are configuring and enter the Interface Configuration mode.
`awplus(config-if)#`	
`switchport trunk allowed vlan add 50`	Enable VLAN 50 on this port.
`awplus(config-if)#`	
`exit`	Exit the Interface Configuration mode and enter the Global Configuration mode.

Select the next transit node that connects to the common segment, and repeat the above steps:

On Ring 1 EPSR Instance Blue - Add VLAN 50 to the Master Node

Carry out this process using the same basic procedure shown in of Steps 1 to 5

On Ring 1 EPSR Instance Blue - Add VLAN 50 to the Transit Nodes

Carry out this process using the same basic procedure shown in of Steps 1 to 5

On Ring 2 EPSR Instance Green - Add VLAN 50 to the Master Node

Carry out this process using the same basic procedure shown in of Steps 1 to 5

On Ring 2 EPSR Instance Green - Add VLAN 50 to the remaining Transit Node

Carry out this process using the same basic procedure shown in of Steps 1 to 5

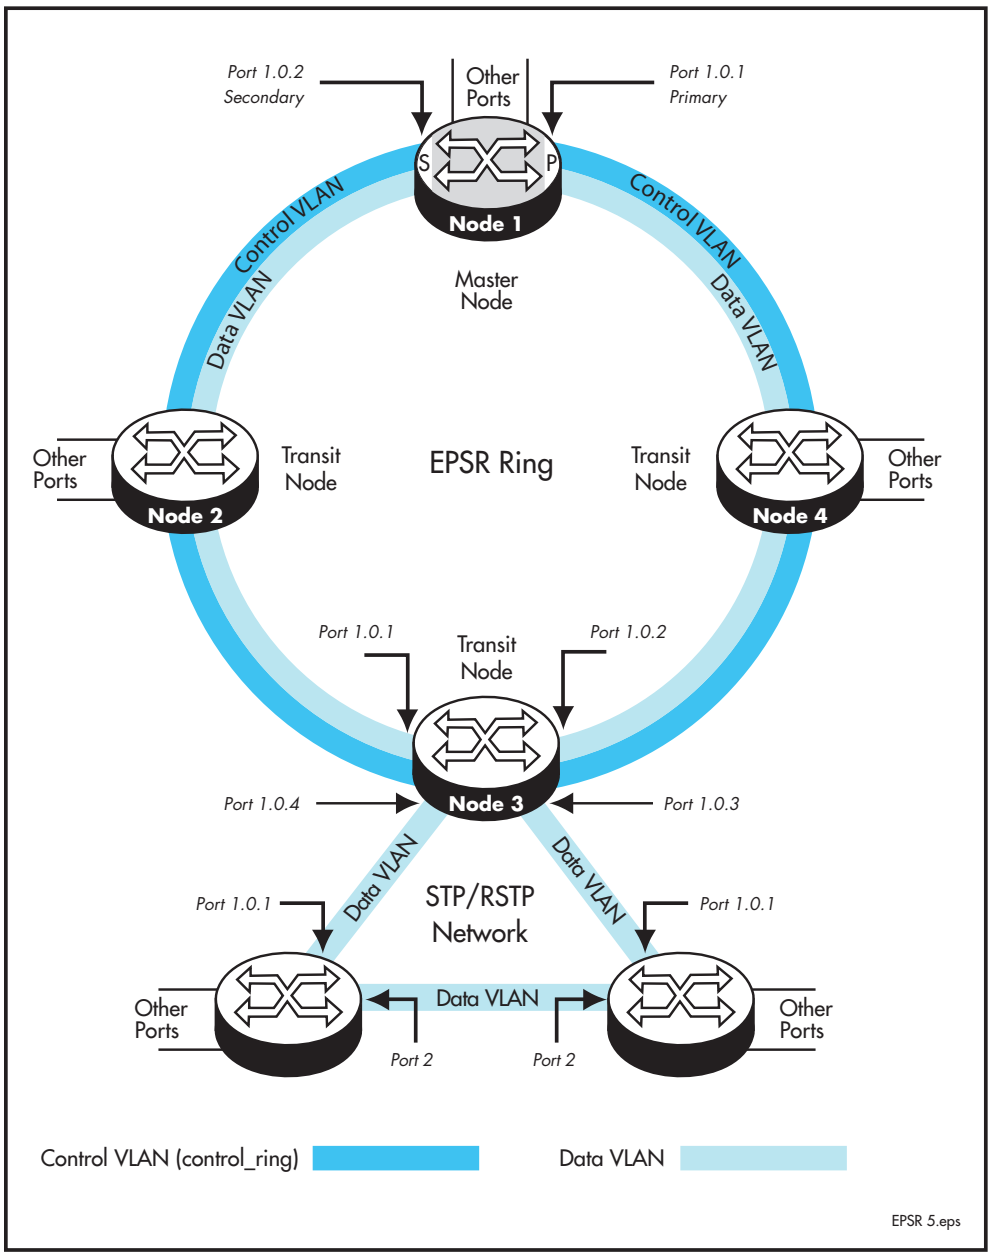
EPSR and Spanning Tree Operation

EPSR and the Spanning Tree protocol (STP) address data loop prevention, although they do it differently. EPSR is manually configured to explicitly identify which links are broken in the defined ring, whereas STP/RSTP calculates where to break links based on user-provided values (metrics) that are compared to determine the "best" (or lowest cost) paths for data traffic.

At the practical level you can use these two techniques to create complementary hybrid EPSR /STP configurations. This configuration might have a high speed fibre loop topology backbone-controlled and managed using EPSR. Lobes could extend out from each loop node into a user mesh network. Any loops in this mesh network would be controlled and managed using STP/RSTP. Note that EPSR and STP cannot share the same ports.

The following figure shows a basic combined EPSR / STP network.

Figure 81-18: EPSR and spanning tree operation



Chapter 82: EPSR Commands

Command List 82.2
debug epsr 82.2
epsr 82.3
epsr configuration 82.4
epsr datavlan 82.5
epsr enhancedrecovery enable 82.6
epsr mode master controlvlan primaryport 82.7
epsr mode transit controlvlan 82.8
epsr priority 82.9
epsr state 82.10
epsr trap 82.11
show debugging epsr 82.11
show epsr 82.12
show epsr word 82.16
show epsr word counters 82.16
show epsr counters 82.17
undebug epsr 82.17

Command List

This chapter provides an alphabetical reference for commands used to configure EPSR. For more information, see Chapter 81, EPSR Introduction and Configuration.

For information about modifying or redirecting the output from show commands to a file, see

"Controlling "show" Command Output" on page 1.41.

debug epsr

This command enables EPSR debugging.

The no variant of this command disables EPSR debugging.

Syntax

```
debug epsr {info|msg|pkt|state|timer|all}
no debug epsr {info|msg|pkt|state|timer|all}
```

Parameter	Description
`info`	Send general EPSR information to the console. Using this parameter with the no debug epsr command will explicitly exclude the above information from being sent to the console.
`msg`	Send the decoded received and transmitted EPSR packets to the console. Using this parameter with the no debug epsr command will explicitly exclude the above packets from being sent to the console.
`pkt`	Send the received and transmitted EPSR packets as raw ASCII text to the console. Using this parameter with the no debug epsr command will explicitly exclude the above packets from being sent to the console.
`state`	Send EPSR state transitions to the console. Using this parameter with the no debug epsr command will explicitly exclude state transitions from being sent to the console.
`timer`	Send EPSR timer information to the console. Using this parameter with the no debug epsr command will explicitly exclude timer information from being sent to the console.
`all`	Send all EPSR debugging information to the console. Using this parameter with the no debug epsr command will explicitly exclude any debugging information from being sent to the console.

Mode Privileged Exec

Examples To enable state transition debugging, use the command:

```
awplus# debug epsr state
```

To disable EPSR packet debugging, use the command:

```
awplus# no debug epsr pkt
```

Related Commands undebug epsr

epsr

This command sets the timer values for an EPSR instance. It is only valid for master nodes.

The no variant of this command destroys an EPSR instance.

Syntax

```
epsr <epsr-name> {hellotime <1-32767>|failovertime <2-65535>|
   ringflaptime <0-65535>}

no epsr <epsr-name>
```

Parameter	Description
<epsr-name>	Name of the EPSR instance.
`hellotime` *<1-32767>*	The interval between transmitting health check messages in seconds.
`failovertime` *<2-65535>*	The period a master waits for a health check before declaring a broken ring in seconds.
`ringflaptime` *<0-65535>*	The minimum period that a master must remain in the failed state in seconds.

Mode EPSR Configuration

Examples To set the hellotimer to 5 seconds for the EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# epsr blue hellotime 5
```

Note The failovertime must be at least twice the hellotime, or the hellotime must be less than equal to half the failovertime. Do not set hellotime at or below failovertime.

Note When VCStack is used with EPSR, the EPSR failovertime must be set to at least 5 seconds to avoid any broadcast storms during failover. Broadcast storms may occur if the switch cannot failover quickly enough before the EPSR failovertime expires. See the reboot rolling command for further information about VCStack failover.

To destroy an EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# no epsr blue
```

epsr configuration

Use this command to enter EPSR Configuration mode so that EPSR can be configured.

Syntax

```
epsr configuration
```

Mode

Global Configuration

Example

To change to EPSR mode, use the command:

```
awplus(config)# epsr configuration
```

Related Commands

epsr mode master controlvlan primaryport
epsr
show epsr

epsr datavlan

This command adds a data VLAN or a range of VLAN identifiers to a specified EPSR instance.

The no variant of this command removes a data vlan or data vlan range from an EPSR instance.

Syntax

```
epsr <epsr-name> datavlan {<vlanid>|<vlanid-range>}
no epsr <epsr-name> datavlan {<vlanid>|<vlanid-range>}
```

Parameter	Description
<epsr-name>	Name of the EPSR instance.
`datavlan`	Adds a data VLAN to be protected by the EPSR instance.
<vlanid>	The VLAN's VID - a number between 1 and 4094 excluding the number selected for the control VLAN.
<vlanid-range>	Specify a range of VLAN identifiers using a hyphen to separate identifiers.

Mode EPSR Configuration

Usage We suggest setting the epsr controlvlan to vlan2 using the epsr mode master controlvlan primaryport and epsr mode transit controlvlan commands, then setting the EPSR data VLAN between to be a value 3 and 4094 using the epsr datavlan command.

Examples To add `vlan3` to the EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# epsr blue datavlan vlan3
```

To add `vlan2` and `vlan3` to the EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# epsr blue datavlan vlan2-vlan3
```

To remove `vlan3` from the EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# no epsr blue datavlan vlan3
```

To remove `vlan2` and `vlan3` from the EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# no epsr blue datavlan vlan2-vlan3
```

Related Commands

epsr mode master controlvlan primaryport
epsr mode transit controlvlan
show epsr

epsr enhancedrecovery enable

This command enables EPSR's enhanced recovery mode. Enhanced recovery mode enables a ring to apply additional recovery procedures when a ring with more than one break, partially mends. For more information see, "Managing Rings with Two Breaks" on page 81.7.

The no variant of this command disables the enhancedrecovery mode.

Syntax

```
epsr <epsr-name> enhancedrecovery enable
no epsr <epsr-name> enhancedrecovery enable
```

Parameter	Description
<epsr-name>	Name of the EPSR instance.

Default Default is enhancedrecovery mode disabled.

Mode EPSR Configuration

Example To apply enhanced recovery on the EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# epsr blue enhancedrecovery enable
```

Related Commands show epsr

epsr mode master controlvlan primaryport

This command creates a master EPSR instance.

Syntax `epsr <epsr-name> mode master controlvlan <2-4094> primaryport <port>`

Parameter	Description
`<epsr-name>`	Name of the EPSR instance.
`mode`	Determines the node is acting as a master.
`master`	Sets switch to be the master node for the named EPSR ring.
`controlvlan`	The VLAN that will transmit EPSR control frames.
`<2-4094>`	VLAN id.
`primaryport`	Primary port for the EPSR instance.
`<port>`	The primary port. The port may be a switch port (e.g. `port1.0.4`) or a static channel group (e.g. `sa3`). It cannot be a dynamic (LACP) channel group.

Note

The software allows you to configure more than two ports or static channel groups to the control VLAN within a single switch or stacked node. However, we advise against this because in certain situations it can produce unpredictable results.

If the control VLAN contains more than two ports (or static channels) an algorithm selects the two ports or channels with the lowest number to be the ring ports. However if the switch has only one channel group is defined to the control vlan, EPSR will not operate on the secondary port.

EPSR does not support Dynamic link aggregation (LACP).

Mode EPSR Configuration

Example To create a master EPSR instance called `blue` with `vlan2` as the control VLAN and `port1.0.1` as the primary port, use the command:

```
awplus(config-epsr)# epsr blue mode master controlvlan vlan2
                     primaryport port1.0.1
```

Related Commands epsr mode transit controlvlan
show epsr

epsr mode transit controlvlan

This command creates a transit EPSR instance.

Syntax `epsr <epsr-name> mode transit controlvlan <2-4094>`

Parameter	Description
<epsr-name>	Name of the EPSR instance.
`mode`	Determines the node is acting as a transit node.
`transit`	Sets switch to be the transit node for the named EPSR ring.
`controlvlan`	The VLAN that will transmit EPSR control.
<2-4094>	VLAN id.

Note

The software allows you to configure more than two ports or static channel groups to the control VLAN within a single switch or stacked node. However, we advise against this because in certain situations it can produce unpredictable results.

If the control VLAN contains more than two ports (or static channels) an algorithm selects the two ports or channels with the lowest number to be the ring ports. However if the switch has only one channel group is defined to the control vlan, EPSR will not operate on the secondary port.

EPSR does not support Dynamic link aggregation (LACP).

Mode EPSR Configuration

Example To create a transit EPSR instance called `blue` with `vlan2` as the control VLAN, use the command:

```
awplus(config-epsr)# epsr blue mode transit controlvlan vlan2
```

Related Commands

epsr mode master controlvlan primaryport

show epsr

epsr priority

This command sets the priority of an EPSR instance on an EPSR node. Priority is used to prevent superloops forming under fault conditions with particular ring configurations. Setting a node to a value greater than one, also has the effect of turning on superloop protection.

The no variant of this command returns the priority of the EPSR instance back to its default value of 0, which also disables EPSR Superloop prevention.

Syntax

```
epsr <epsr-name> priority <0-127>
no <epsr-name> priority
```

Parameter	Description
<epsr-name>	Name of the EPSR instance.
`priority`	The priority of the ring instance selected by the epsr-name parameter.
<0-127>	The priority to be applied (0 is the lowest priority and represents no superloop protection.

Default The default priority of an EPSR instance on an EPSR node is 0. The negated form of this command resets the priority of an EPSR instance on an EPSR node to the default value.

Mode EPSR Configuration

Example To set the priority of the EPSR instance called `blue` to the highest priority (127), use the command:

```
awplus(config-epsr)# epsr blue priority 127
```

To reset the priority of the EPSR instance called `blue` to the default (0), use the command:

```
awplus(config-epsr)# no epsr blue priority
```

Related Commands epsr configuration

epsr state

This command enables or disables an EPSR instance.

Syntax `epsr <epsr-name> state {enabled|disabled}`

Parameter	Description
`<epsr-name>`	The name of the EPSR instance.
`state`	The operational state of the ring.
`enabled`	EPSR instance is enabled.
`disabled`	EPSR instance is disabled.

Mode EPSR Configuration

Example To enable the EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# epsr blue state enabled
```

Related Commands epsr mode master controlvlan primaryport
epsr mode transit controlvlan

epsr trap

This command enables SNMP traps for an EPSR instance. The traps will be sent when the EPSR instance changes state.

The no variant of this command disables SNMP traps for an EPSR instance. The traps will no longer be sent when the EPSR instance changes state.

Syntax

```
epsr <epsr-name> trap
no epsr <epsr-name> trap
```

Parameter	Description
<epsr-name>	Name of the EPSR instance.
`trap`	SNMP trap for the EPSR instance.

Mode EPSR Configuration

Example To enable traps for the EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# epsr blue trap
```

To disable traps for the EPSR instance called `blue`, use the command:

```
awplus(config-epsr)# no epsr blue trap
```

Table 82-1: Parameters displayed in the output of the **show lacp** command

Parameter on Master Node	Parameter on Transit Node	Description
Name	Name	The name of the EPSR instance.
Mode	Mode	The mode in which the EPSR instance is configured - either Master or Transit
Status	Status	Indicates whether the EPSR instance is enabled or disabled
State	State	Indicates state of the EPSR instance's state machine. Master states are: Idle, Complete, and Failed. Transit states are Links-Up, Links-Down, and Pre-Forwarding.
Control Vlan	Control Vlan	Displays the VID of the EPSR instance's control VLAN.
Data VLAN(s)	Data VLAN(s)	The VID(s) of the instance's data VLANs.
Interface Mode	Interface Mode	Whether the EPSR instance's ring ports are both physical ports (Ports Only) or are both static aggregators (Channel Groups Only).
Primary Port	First Port	The EPSR instance's primary ring port.
- Status	- Status	Whether the ring port is forwarding (Forwarding) or blocking (Blocked), or has link down (Down), and if forwarding or blocking, "(logical)" indicates the instance has only logically set the blocking state of the port because it does not have physical control of it.
	- Direction	The ring port on which the last EPSR control packet was received is indicated by "Upstream". The other ring port is then "Downstream"

Table 82-1: Parameters displayed in the output of the **show lacp** command

Parameter on Master	Parameter on Transit	Description(cont.)
- Is On Common Segment	- Is On Common Segment	Whether the ring port is on a shared common segment link to another node, and if so, "(highest rank)" indicates it is the highest priority instance on that common segment.
- Blocking Control	- Blocking Control	Whether the instance has "physical" or "logical" control of the ring port's blocking in the instance's data VLANs.
Secondary Port	Second Port	The EPSR instance's secondary port.
- Status	- Status	Whether the ring port is forwarding (Forwarding) or blocking (Blocked), or has link down (Down), and if forwarding or blocking, "(logical)" indicates the instance has only logically set the blocking state of the port, because it does not have physical control of it. Note that on a master configured for SuperLoop Prevention (non-zero priority) its secondary ring port can be physically forwarding, but logically blocking. This situation arises when it is not the highest priority node in the topology (and so does not receive LINKS-DOWN messages upon common segment breaks) and a break on a common segment in its ring is preventing reception of its own health messages.
	- Direction	The ring port on which the last EPSR control packet was received is indicated by "Upstream". The other ring port is then "Downstream"
- Is On Common Segment	- Is On Common Segment	Whether the ring port is on a shared common segment link to another node, and if so, "(highest rank)" indicates it is the highest priority instance on that common segment
- Blocking Control	- Blocking Control	Whether the instance has "physical" or "logical" control of the ring port's blocking in the instance's data VLANs
Hello Time		The EPSR instance's setting for the interval between transmissions of health check messages (in seconds)
Failover Time		The time (in seconds) the EPSR instance waits to receive a health check message before it decides the ring is down
Ring Flap Time		The minimum time the EPSR instance must remain in the failed state
Trap	Trap	Whether the EPSR instance has EPSR SNMP traps enabled
Enhanced Recovery	Enhanced Recovery	Whether the EPSR instance has enhanced recovery mode enabled
SLP Priority	SLP Priority	The EPSR instance's priority (for SuperLoop Prevention)

Chapter 83: NTP Introduction and Configuration

Introduction 83.2
Overview 83.2
NTP on the Switch 83.3
Troubleshooting 83.4
Configuration Example 83.5

Introduction

This chapter describes the Network Time Protocol (NTP) service provided by the switch, and how to configure and monitor NTP on the switch.

NTP is a protocol for synchronizing the time clocks on a collection of network devices using a distributed client/server mechanism. NTP uses UDP (User Datagram Protocol) as the transport mechanism. NTP evolved from the Time Protocol (RFC 868) and the ICMP Timestamp message (RFC 792).

NTP provides protocol mechanisms to specify the precision and estimated error of the local clock and the characteristics of the reference clock to which it may be synchronized.

For detailed information about the commands used to configure NTP, see Chapter 84, NTP Commands.

Overview

NTP uses a subnetwork with primary reference clocks, gateways, secondary reference clocks, and local hosts. These are organized into a hierarchy with the more accurate clocks near the top and less accurate ones near the bottom.

A number of primary reference clocks, synchronized to national standards, are connected to widely accessible resources (such as backbone gateways or switches) operating as primary time servers. The primary time servers use NTP between them to crosscheck clocks, to mitigate errors due to equipment or propagation failures, and to distribute time information to local secondary time servers. The secondary time servers redistribute the time information to the remaining local hosts.

The hierarchical organization and distribution of time information reduces the protocol overhead, and allows selected hosts to be equipped with cheaper but less accurate clocks. NTP provides information which organizes this hierarchy on the basis of precision or estimated error.

- An NTP entity may be in one of the following operating modes; however, the switch's implementation of NTP supports two modes: client and server.
- An NTP entity operating in a client mode sends periodic messages to its peers, requesting synchronization by its peers.
- An NTP entity enters the server mode temporarily when it receives a client request message from one of its peers, and remains in server mode until the reply to the request has been transmitted.
- An NTP entity operating in symmetric active mode sends messages announcing its willingness to synchronize and be synchronized by its peers.
- An NTP entity enters symmetric passive mode in response to a message from a peer operating in Symmetric Active mode. An NTP entity operating in this mode announces its willingness to synchronize and be synchronized by its peers.
- An NTP entity operating in broadcast mode periodically sends messages announcing its willingness to synchronize all of its peers but not to be synchronized by any of them.

The same message format is used for both requests and replies. When a request is received, the server interchanges addresses and ports, fills in or overwrites certain fields in the message, recalculates the checksum, and returns it immediately. The information included in the NTP message allows each client/ server peer to determine the timekeeping characteristics of its peers, including the expected accuracies of their clocks. Each peer uses this information and selects the best time from possibly several other clocks, updates the local clock, and estimates its accuracy.

There is no provision in NTP for peer discovery, acquisition, or authentication. Data integrity is provided by the IP and UDP checksums. No reachability, circuit-management, duplicate-detection, or retransmission facilities are provided or necessary.

By its very nature clock synchronization requires long periods of time (hours or days) and multiple comparisons in order to maintain accurate timekeeping. The more comparisons performed, the greater the accuracy of the timekeeping.

NTP on the Switch

The implementation of NTP on the switch is based on the following RFCs:

- RFC 958, Network Time Protocol (NTP)
- RFC 1305, Network Time Protocol (Version 3) Specification, Implementation and Analysis
- RFC 1510, The Kerberos Network Authentication Service (V5)

Two modes of operation are supported: client and server. The switch is in client mode most of the time where it polls the configured peer at least once every preconfigured minimum time period.

The peer that the switch refers to must be a more accurate clock source than the switch itself or another switch directly connected to a more accurate clock source. The switch operates as a secondary time server. It cannot operate as a primary time server unless the primary clock source is operating in server mode. A primary clock source usually operates in broadcast mode, which is not supported by the switch's implementation of NTP. There is no support for clock selection or filtering. When the switch receives a valid reply from the peer, it synchronizes its own internal clock according to the information from the reply.

If the switch receives a synchronization request from an NTP client, it temporarily changes to server mode. It replies to the request with the current time from the switch's internal clock along with other information useful for synchronization. The switch's internal clock is accurate to 0.005 seconds.

Troubleshooting

Problem The switch is not assigning the time to devices on the LAN.

Solutions

- Check that the NTP peer's IP address is entered correctly.
- Check that the NTP peer can reach the switch, by pinging the switch from the NTP peer.

Problem The switch's clock does not synchronize with the NTP peer.

Solution

- The switch's clock can synchronize with the NTP peer only when its initial time is similar to the NTP peer's time (after setting the UTC offset). Manually set the switch's time so that it is approximately correct, and enable NTP again.
- Check that the UTC offset is correct.

Problem The switch's time is incorrect, even though it assigns the correct time to devices on the LAN.

Solution The UTC offset is probably incorrect, or needs to be adjusted for the beginning or end of summer time.

Configuration Example

NTP requires the IP module to be enabled and configured correctly.

The switch's implementation of NTP supports two modes: client and server mode. When a synchronization request is received from a client (e.g. a PC on a LAN), the switch enters server mode and responds with time information derived from the switch's own internal clock. Periodically the switch enters client mode, sending synchronization requests to a predefined peer to synchronize its own internal clock. The peer is assumed to be a primary clock source or another switch connected directly to a primary clock source.

This example illustrates how to configure two switches, one at a Head Office and one at a Regional Office, to provide a network time service. The Head Office switch is connected to a primary time server and provides the most accurate time information. The switch at the Regional Office uses the Head Office switch as its peer to avoid the cost of an additional WAN connection but provides slightly less accurate time information.

To configure NTP on the switch, the NTP module must be enabled and an NTP peer must be defined. NTP transfers time information in UTC format.

To set the switch to automatically change the time when summer time starts and ends, enable a summer time offset setting.

Example configuration parameters for a network time service:

Site	Regional Office	Head Office
Switch Name	RG1	HO1
IP Address of Switch	192.168.35.114	192.168.35.113
IP Address of Peer	192.168.35.113	192.168.13.3

Step 1: Enable NTP and define the NTP peer.

The NTP feature must be enabled on all switches that are to provide a network time service. Each switch must have a peer defined where the switch synchronizes its own internal clock. Enable NTP on the Head Office switch and specify a primary time server as the peer by using the commands:

```
awplus# configure terminal
awplus(config)# ntp peer 192.168.13.3
```

Note that you can also specify an IPv6 address for an NTP peer:

```
awplus# configure terminal
awplus(config)# ntp peer 2001:0db8:010d::1
```

Step 2: Configure the NTP parameters.

On each switch, the offset of local time from UTC time must be specified. In this example, both switches are in the same time zone, which is 12 hours ahead of UTC time. Use the following commands on both switches:

```
awplus(config)# clock timezone utc plus 12
```

Note that the range of offset is `<0-12>`.

Step 3: Check the NTP configuration.

Check the NTP configuration on each switch by using the command:

```
awplus# show ntp status
```

This command displays the following information on the Head Office switch.

```
Clock is synchronized, stratum 0, actual frequency is 0.0000
Hz, precision is 20 reference time is 00000000.00000000
(6:28:16.000 UTC Fri Feb  7 2036)clock offset is 0.000 msec,
root delay is 0.000 msec root dispersion is 0.000 msec,
```

Chapter 84: NTP Commands

Command List 84.2
ntp access-group 84.2
ntp authenticate 84.3
ntp authentication-key 84.4
ntp broadcastdelay 84.5
ntp master 84.6
ntp peer 84.7
ntp server 84.9
ntp trusted-key 84.11
show counter ntp 84.12
show ntp associations 84.13
show ntp status 84.14

Command List

This chapter provides an alphabetical reference for commands used to configure the Network Time Protocol (NTP). For more information, see Chapter 83, NTP Introduction and Configuration.

For information about modifying or redirecting the output from show commands to a file, see "Controlling "show" Command Output" on page 1.41.

ntp access-group

This command creates an NTP access group, and applies a basic IP access list to it. This allows you to control access to NTP services.

The no variant of this command removes the configured NTP access group.

Syntax

```
ntp access-group [peer|query-only|serve|serve-only]
    [<1-99>|<1300-1999>]

no ntp access-group [peer|query-only|serve|serve-only]
```

Parameter	Description
`peer`	Allows time requests and NTP control queries, and allows the system to synchronize itself to a system whose address passes the access list criteria.
`query-only`	Allows only NTP control queries from a system whose address passes the access list criteria.
`serve`	Allows time requests and NTP control queries, but does not allow the system to synchronize itself to a system whose address passes the access list criteria.
`serve-only`	Allows only time requests from a system whose address passes the access list criteria.
<1-99>	Standard IP access list.
<1300-1999>	Expanded IP access list.

Mode Global Configuration

Example To create an NTP peer access group for an extended IP access list, use the commands:

```
awplus# configure terminal
awplus(config)# ntp access-group peer 1998
```

To disable the NTP peer access group created above, use the commands:

```
awplus# configure terminal
awplus(config)# no ntp access-group peer
```

ntp authenticate

This command enables NTP authentication. This allows NTP to authenticate the associations with other systems for security purposes.

The no variant of this command disables NTP authentication.

Syntax

```
ntp authenticate
no ntp authenticate
```

Mode Global Configuration

Example To enable NTP authentication, use the commands:

```
awplus# configure terminal
awplus(config)# ntp authenticate
```

To disable NTP authentication, use the commands:

```
awplus# configure terminal
awplus(config)# no ntp authenticate
```

ntp authentication-key

This command defines each of the authentication keys. Each key has a key number, a type, and a value. Currently, the only key type supported is MD5.

The no variant of this disables the authentication key assigned previously using ntp authentication-key.

Syntax

```
ntp authentication-key <keynumber> md5 <key>
no ntp authentication-key <keynumber> md5 <key>
```

Parameter	Description
<keynumber>	*<1-4294967295>* The key number.
<key>	The authentication key.

Mode Global Configuration

Example To define an authentication key number `134343` and a key value `mystring`, use the commands:

```
awplus# configure terminal
awplus(config)# ntp authentication-key 134343 md5 mystring
```

To disable the authentication key number `134343` with the key value `mystring`, use the commands:

```
awplus# configure terminal
awplus(config)# no ntp authentication-key 134343 md5 mystring
```

ntp broadcastdelay

Use this command to set the estimated round-trip delay for broadcast packets.

Use the no variant of this command to reset the round-trip delay for broadcast packets to the default offset of 0 microseconds.

Syntax

```
ntp broadcastdelay <delay>
no ntp broadcastdelay
```

Parameter	Description
<delay>	*<1-999999>* The broadcast delay in microseconds.

Default 0 microsecond offset, which can only be applied with the no variant of this command.

Mode Global Configuration

Example To set the estimated round-trip delay to 23464 microseconds for broadcast packets, use these commands:

```
awplus# configure terminal
awplus(config)# ntp broadcastdelay 23464
```

To reset the estimated round-trip delay for broadcast packets to the default setting (0 microseconds), use these commands:

```
awplus# configure terminal
awplus(config)# no ntp broadcastdelay
```

ntp master

Use this command to make the device to be an authoritative NTP server, even if the system is not synchronized to an outside time source. Note that no stratum number is set by default.

Use the no variant of this command to stop the device being the designated NTP server.

Syntax

```
ntp master [<stratum>]
no ntp master
```

Parameter	Description
<stratum>	*<1-15>* The stratum number.

Mode Global Configuration

Usage The stratum number is null by default and must be set using this command. The stratum levels define the distance from the reference clock and exist to prevent cycles in the hierarchy. Stratum 1 is used to indicate time servers, which are more accurate than Stratum 2 servers.

Examples To stop the switch from being the designated NTP server use the commands:

```
awplus# configure terminal
awplus(config)# no ntp master
```

To make the switch the designated NTP server with stratum number 2 use the commands:

```
awplus# configure terminal
awplus(config)# ntp master 2
```

ntp peer

Use this command to configure an NTP peer association. An NTP association is a peer association if this system is willing to either synchronize to the other system, or allow the other system to synchronize to it.

Use the no variant of this command to remove the configured NTP peer association.

Syntax

```
ntp peer {<peeraddress>|<peername>}

ntp peer {<peeraddress>|<peername>}
   [prefer] [key <key>] [version <version>]

no ntp peer {<peeraddress>|<peername>}
```

Parameter	Description
<peeraddress>	Specify the IP address of the peer, entered in the form `A.B.C.D` for an IPv4 address, or in the form `X:X::X.X` for an IPv6 address.
<peername>	Specify the peer hostname. The peer hostname can resolve to an IPv4 and an IPv6 address.
`prefer`	Prefer this peer when possible.
`key` *<key>*	*<1-4294967295>* Configure the peer authentication key.
`version` *<version>*	*<1-4>* Configure for this NTP version.

Mode Global Configuration

Examples See the following commands for options to configure NTP peer association, key and NTP version for the peer with an IPv4 address of `192.0.2.23`:

```
awplus# configure terminal
awplus(config)# ntp peer 192.0.2.23
awplus(config)# ntp peer 192.0.2.23 prefer
awplus(config)# ntp peer 192.0.2.23 prefer version 4
awplus(config)# ntp peer 192.0.2.23 prefer version 4 key 1234
awplus(config)# ntp peer 192.0.2.23 version 4 key 1234
awplus(config)# ntp peer 192.0.2.23 version 4
awplus(config)# ntp peer 192.0.2.23 key 1234
```

To remove an NTP peer association for this peer with an IPv4 address of `192.0.2.23`, use the following commands:

```
awplus# configure terminal
awplus(config)# no ntp peer 192.0.2.23
```

See the following commands for options to configure NTP peer association, key and NTP version for the peer with an IPv6 address of 2001:0db8:010d::1:

```
awplus# configure terminal
awplus(config)# ntp peer 2001:0db8:010d::1
awplus(config)# ntp peer 2001:0db8:010d::1 prefer
awplus(config)# ntp peer 2001:0db8:010d::1 prefer version 4
awplus(config)# ntp peer 2001:0db8:010d::1 prefer version 4 key
1234
awplus(config)# ntp peer 2001:0db8:010d::1 version 4 key 1234
awplus(config)# ntp peer 2001:0db8:010d::1 version 4
awplus(config)# ntp peer 2001:0db8:010d::1 key 1234
```

To remove an NTP peer association for this peer with an IPv6 address of 2001:0db8:010d::1, use the following commands:

```
awplus# configure terminal
awplus(config)# no ntp peer 2001:0db8:010d::1
```

ntp server

Use this command to configure an NTP server. This means that this system will synchronize to the other system, and not vice versa.

Use the no variant of this command to remove the configured NTP server.

Syntax

```
ntp server {<serveraddress>|<servername>}

ntp server {<serveraddress>|<servername>}
    [prefer] [key <key>] [version <version>]

no ntp server {<serveraddress>|<servername>}
```

Parameter	Description
<serveraddress>	Specify the IP address of the peer, entered in the form `A.B.C.D` for an IPv4 address, or in the form `X:X::X.X` for an IPv6 address.
<servername>	Specify the server hostname. The server hostname can resolve to an IPv4 and an IPv6 address.
`prefer`	Prefer this server when possible.
`key` *<key>*	*<1-4294967295>* Configure the server authentication key.
`version` *<version>*	*<1-4>* Configure for this NTP version.

Mode Global Configuration

Examples See the following commands for options to configure an NTP server association, key and NTP version for the server with an IPv4 address of `192.0.1.23`:

```
awplus# configure terminal
awplus(config)# ntp server 192.0.1.23
awplus(config)# ntp server 192.0.1.23 prefer
awplus(config)# ntp server 192.0.1.23 prefer version 4
awplus(config)# ntp server 192.0.1.23 prefer version 4 key 1234
awplus(config)# ntp server 192.0.1.23 version 4 key 1234
awplus(config)# ntp server 192.0.1.23 version 4
awplus(config)# ntp server 192.0.1.23 key 1234
```

To remove an NTP peer association for this peer with an IPv4 address of `192.0.1.23`, use the following commands:

```
awplus# configure terminal
awplus(config)# no ntp server 192.0.1.23
```

See the following commands for options to configure an NTP server association, key and NTP version for the server with an IPv6 address of 2001:0db8:010e::2:

```
awplus# configure terminal
awplus(config)# ntp server 2001:0db8:010e::2
awplus(config)# ntp server 2001:0db8:010e::2 prefer
awplus(config)# ntp server 2001:0db8:010e::2 prefer version 4
awplus(config)# ntp server 2001:0db8:010e::2 prefer version 4
key 1234
awplus(config)# ntp server 2001:0db8:010e::2 version 4 key 1234
awplus(config)# ntp server 22001:0db8:010e::2 version 4
awplus(config)# ntp server 2001:0db8:010e::2 key 1234
```

To remove an NTP peer association for this peer with an IPv6 address of 2001:0db8:010e::2, use the following commands:

```
awplus# configure terminal
awplus(config)# no ntp server 2001:0db8:010e::2
```

ntp trusted-key

This command defines a list of trusted authentication keys. If a key is trusted, this system will be ready to synchronize to a system that uses this key in its NTP packets.

Use the no variant of this command to remove a configured trusted authentication key.

Syntax

```
ntp trusted-key <1-4294967295>
no ntp trusted-key <1-4294967295>
```

Parameter	Description
<*1-4294967295*>	The specific key number.

Mode Global Configuration

Example To define a trusted authentication key numbered `234675`, use the following commands:

```
awplus# configure terminal
awplus(config)# ntp trusted-key 234676
```

To remove the trusted authentication key numbered `234675`, use the following commands:

```
awplus# configure terminal
awplus(config)# no ntp trusted-key 234676
```

show counter ntp

This command displays packet counters for NTP.

Syntax `show counter ntp`

Mode User Exec and Privileged Exec

Output Figure 84-1: Example output from the **show counter ntp** command

```
NTP counters
Pkts Sent                .......... 0
Pkts Received            .......... 70958
Pkts Processed           .......... 0
Pkts current version     .......... 0
Pkts old version         .......... 0
Pkts unknown version     .......... 0
Pkts access denied       .......... 70958
Pkts bad length          .......... 0
Pkts bad auth            .......... 0
Pkts rate exceed         .......... 0
```

Table 84-1: Parameters in the output from the **show counter ntp** command

Parameter	Description
`Pkts Sent`	Total number of NTP client and server packets sent by your device.
`Pkts Received`	Total number of NTP client and server packets received by your device.
`Pkts Processed`	The number of packets processed by NTP. NTP processes a packet once it has determined that the packet is valid by checking factors such as the packet's authentication, format, access rights and version.
`Pkts current version`	The number of version 4 NTP packets received.
`Pkts old version`	The number of NTP packets received that are from an older version, down to version 1, of NTP. NTP is compatible with these versions and processes these packets.
`Pkts unknown version`	The number of NTP packets received that are an earlier version than version 1, or a higher version than version 4. NTP cannot process these packets.
`Pkts access denied`	The number of NTP packets received that do not match any access list statements in the NTP access-groups. NTP drops these packets.
`Pkts bad length`	The number of NTP packets received that do not conform to the standard packet length. NTP drops these packets.
`Pkts bad auth`	The number of NTP packets received that failed authentication. NTP drops these packets. Packets can only fail authentication if NTP authentication is enabled with the ntp authenticate command.
`Pkts rate exceed`	The number of packets dropped because the packet rate exceeded its limits.

Example To display counters for NTP, use the command:

```
awplus# show counter ntp
```

show ntp associations

Use this command to display the status of NTP associations. Use the detail option for displaying detailed information about the associations.

Syntax `show ntp associations [detail]`

Mode User Exec and Privileged Exec

Example See the sample output of the show ntp associations and show ntp associations detail commands displaying the status of NTP associations

Figure 84-2: Example output from the **show ntp associations** command

```
awplus#show ntp associations
  address          ref clock       st  when  poll reach   delay  offset    disp

Table 84-2: Parameters in the output from the **show ntp associations** command

Parameter	Description
address	Peer IP address
ref clock	IP address for reference clock
st	Stratum. The number of hops between the server and the accurate time source.
poll	Time between NTP requests from the device to the server.
reach	Shows whether or not the NTP server responded to the last request.
delay	Round trip delay between the device and the server.
offset	Difference between the device clock and the server clock.
disp	Lowest measure of error associated with peer offset based on delay.

show ntp status

Use this command to display the status of the Network Time Protocol (NTP).

Syntax `show ntp status`

Mode User Exec and Privileged Exec

Example See the sample output of the show ntp status command displaying information about the Network Time Protocol.

Figure 84-4: Example output from the s**how ntp status** command

```
awplus#sh ntp status
Clock is synchronized, stratum 3, reference is 127.127.1.0
actual frequency is 0.0000 Hz, precision is 2**-19
reference time is cf11f3f2.c7c081a1 (00:44:34.780 UTC Tue Feb  2
2010)
clock offset is 0.000 msec, root delay is 0.000 msec
root dispersion is 7947729.000 msec,

Chapter 85: Dynamic Host Configuration Protocol (DHCP) Introduction

Introduction 85.2
- BOOTP 85.2
- DHCP 85.2
- DHCP Relay Agents 85.2

Configuring the DHCP Server 85.3
- Create the Pool 85.3
- Define the Network 85.3
- Define the Range 85.4
- Set the Lease 85.4
- Enable DHCP Leasequery 85.5
- Set the Options 85.6
- DHCP Lease Probing 85.7

DHCP Relay Agent Introduction 85.8
- Configuring the DHCP Relay Agent 85.8
- DHCP Relay Agent Option 82 ..... 85.9

Configuring the DHCP Client 85.12

Clearing Dynamically Allocated Lease Bindings 85.12

Introduction

This chapter describes the Dynamic Host Configuration Protocol (DHCP) support provided by your device. This includes how to configure your device to:

- act as a DHCP and BOOTP server
- act as a DHCP relay agent
- use the DHCP client to obtain IP addresses for its own interfaces

Note that you can configure your device to operate as both a DHCP relay agent and a DHCP/BOOTP server.

BOOTP

Bootstrap Protocol (BOOTP) is a UDP-based protocol that enables a booting host to dynamically configure itself without external interventions. A BOOTP server responds to requests from BOOTP clients for configuration information, such as the IP address the client should use. BOOTP is defined in RFC 951, Bootstrap Protocol (BOOTP).

RFC 1542, Clarifications and Extensions for the Bootstrap Protocol, defines extensions to the BOOTP protocol, including the behavior of a DHCP relay agent.

DHCP

DHCP is widely used to dynamically assign host IP addresses from a centralized server that reduces the overhead of administrating IP addresses. DHCP helps conserve the limited IP address space because IP addresses no longer need to be permanently assigned to hosts. DHCP centrally manages IP address assignment for a large number of subscribers.

DHCP is based on BOOTP, and is defined in RFC 2131. It extends the BOOTP mechanism by providing:

- a method for passing configuration information to hosts on a TCP/IP network
- automatic allocation of reusable network addresses
- other additional configuration options

When your device is configured as a DHCP server, it allocates IP addresses and other IP configuration parameters to clients (hosts), when the client requests them. This lets you configure your IP network without manually configuring every client. Note that each client must also be configured to receive its IP address automatically.

As well as addresses, a DHCP server assigns a wide range of parameters to clients, including subnet information and mask, domain and hostname, server addresses, keepalive times, MTUs, boot settings, encapsulation settings, time settings, and TCP settings.

DHCP is designed to interoperate with BOOTP clients and DHCP clients, without the BOOTP clients needing any change to their initialization software.

DHCP Relay Agents

DHCP relay agents pass BOOTP and DHCP messages between servers and clients. Networks where the DHCP or BOOTP server does not reside on the same IP subnet as its clients need the intermediate routers to act as relay agents. A maximum number of 400 DHCP relay agents (one per interface) can be configured on the device. Once this limit has been reached, any further attempts to configure DHCP relay agents will not be successful.

Configuring the DHCP Server

The DHCP server uses address pools when responding to DHCP client requests. Address pools contains specific IP configuration details that the DHCP server can allocate to a client. You can configure multiple address pools on the device for different networks.

To configure a pool, you must:

- Create the Pool and enter its configuration mode.
- Define the Network the pool applies to.
- Define the Range of IP addresses that the server can allocate to clients. You can specify multiple address ranges for each pool.
- Set the Lease for the clients. This defines whether the clients receive a dynamic, permanent, or static IP address.
- Set the Options (standard and user-defined) that the clients of a pool require when configuring their IP details.

After configuring the address pools, you can then enable the DHCP server by using the command:

```
awplus(config)# service dhcp-server
```

For networks where you do not want the server to respond to BOOTP requests, you can configure the DHCP server so that it ignores them, by using the command:

```
awplus(config)# ip dhcp bootp ignore
```

Create the Pool

A DHCP pool is identified by a name. To create a DHCP pool and enter the configuration mode for the pool, use the command:

```
awplus(config)# ip dhcp pool <pool-name>
```

Define the Network

Define the network that the DHCP clients are in. You can define one network per address pool. Use the following command to define the network after defining the DHCP pool first:

```
awplus(dhcp-config)# network
```

- For remote clients, set the network address to the network of the remote clients. The network command does not need to match a specific interface's network, because the DHCP server listens on all IP interfaces for DHCP requests.
- For locally connected clients, ensure that the desired interface has an IP address and subnet mask defined; use the ip address IPADDR command to set a static address. Enter the configuration mode for the pool, and set the DHCP address pool's network to match the interface's network. Pools that span multiple interfaces are possible only if the interface networks are contiguous.

Define the Range

Configure an IP address range for the pool. This range must be in the same subnet as the pool's network setting. Use the command:

```
awplus(dhcp-config)# range <ip-address> [<ip-address>]
```

The first IPv4 address specifies the low end of the range, while the second IP address is the high end. You can set the range to a single IP address by specifying only one IP address.

Set the Lease

The DHCP server assigns IP settings to hosts for specific times (the lease time). Each DCHP pool has one lease time setting. You can use DHCP to allocate the following types of addresses:

- A dynamic IP addresses
  These are available to a host for a limited amount of time. When the lease expires, the server can reallocate the IP address to another device. To set the lease time for the DHCP pool so that it assigns dynamic IP addresses, use the command:

  ```
  awplus(dhcp-config)# lease <days> <hours> <minutes>
                       [<seconds>]
  ```

- A permanent IP addresses
  These are available to a host for an unlimited amount of time. To set the lease time to assign permanent IP addresses, use the command:

  ```
  awplus(dhcp-config)# lease infinite
  ```

- A static IP addresses
  These are allocated to a particular client. The DHCP server recognizes the client by its MAC address. This lets you use DHCP to manage most of your network automatically, while having unchanging IP addresses on key devices such as servers. To assign a static IP address to a device, use the command:

  ```
  awplus(dhcp-config)# host <ip-address> <mac-address>
  ```

BOOTP requests can be satisfied by pools with leases set to infinity.

Enable DHCP Leasequery

The DHCP Leasequery protocol (RFC 4388) allows a device or process, for example a DHCP relay agent, to obtain IP address information directly from the DHCP server using DHCPLEASEQUERY messages.

DHCPLEASEQUERY messages support three query regimes:

- IP address

  Only an IP address is supplied in the DHCPLEASEQUERY message. The DHCP server will return any information that it has on the most recent client to have been assigned that IP address.

- MAC address

  Only a MAC address is supplied in the DHCPLEASEQUERY message. The DHCP server will return any information that it has on the IP address most recently accessed by a client with that MAC address. Also, the DHCP server may supply additional IP addresses that have been associated with that MAC address in different subnets.

- Client identifier option

  Only a Client identifier option is supplied in the DHCPLEASEQUERY message. The DHCP server will return any information that it has on the IP address most recently accessed by a client with that Client identifier. Also, the DHCP server may supply additional IP addresses that have been associated with Client identifier in different subnets.

An AlliedWare Plus DHCP server implementing DHCP Leasequery supports all three query regimes.

If the DHCP Leasequery feature is enabled, when a DHCP relay agent needs to know the location of an IP endpoint and sends a DHCPLEASEQUERY message, the DHCP server will reply with either a DHCPLEASEACTIVE, DHCPLEASEUNASSIGNED, or DHCPLEASEUNKNOWN message.

When the DHCP server replies to a DHCPLEASEQUERY message:

- a DHCPLEASEACTIVE message allows the DHCP relay agent to determine the IP endpoint location and the remaining duration of the IP address lease
- a DHCPLEASEUNASSIGNED message indicates that there is no current active lease for the IP address, but the DHCP server does manage that IP address
- a DHCPLEASEUNKNOWN message indicates that the DHCP server supports DHCP Leasequery but has no knowledge of the query information specified in the DHCPLEASEQUERY message (e.g., IP address, MAC address, or Client identifier option)

To enable the DHCP Leasequery feature, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp leasequery enable
```

To disable the DHCP Leasequery feature, use the commands:

```
awplus# configure terminal
awplus(config)# no ip dhcp leasequery enable
```

To display information about DHCP Leasequery messages, use either of the commands:

```
awplus# show counter dhcp-server
awplus# show ip dhcp server statistics
```

To display information about the current configuration of the DHCP server, including whether the DHCP server is configured to support DHCP Leasequery, use the command:

```
awplus# show ip dhcp server summary
```

Set the Options

DHCP allows clients to receive options from the DHCP server. Options describe the network configuration, and various services that are available on the network. Options are configured separately on each DHCP pool. You can configure both standard predefined options and user-defined options for a DHCP pool.

To create a user-defined option, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp option <1-254> [name <option-
name>] [<option-type>]
```

To add a user-defined option to a DHCP address pool, use the command sequence:

```
awplus(config)# ip dhcp pool <pool-name>
awplus(dhcp-config)# option [<1-254>|<option-name>]
<option-value>
```

It is possible to add a user-defined option with the same number as an existing pre-defined option. If this situation occurs, the user-defined option takes precedence—that is, it overrides but does not eliminate the standard option.

You can set some pre-defined options using the following commands:

To set a subnet mask (option 1) for the address pool, use the command:

```
awplus(dhcp-config)# subnet-mask <mask>
```

To add a domain name (option 15) for the address pool, use the command:

```
awplus(dhcp-config)# domain-name <domain-name>
```

To add a default router (option 3) for the address pool, use the command:

```
awplus(dhcp-config)# default-router <ip-address>
```

To add a DNS server (option 6) for the address pool, use the command:

```
awplus(dhcp-config)# dns-server <ip-address>
```

DHCP Lease Probing

Probing is used by the DHCP server to check whether an IP address it wants to lease to a client is already being used by another host. Probing is configured on a per-DHCP pool basis. You can specify probing either by ICMP Echo Request (ping) or by ARPing. ARP probing is useful in networks where ICMP may be blocked on some devices, whereas ARP is always supported. ARP and ping probing are mutually exclusive and cannot operate concurrently within a DHCP pool.

Probing is enabled by default when a DHCP pool is created.

To enable probing if probing has previously been disabled for a DHCP pool, enter the configuration mode for the pool with the ip dhcp pool command and then use the command:

```
awplus(dhcp-config)# probe enable
```

The default probe type is ping. To specify the probe type as ARP, enter the configuration mode for the pool and then use the command:

```
awplus(dhcp-config)# probe type arp
```

To set the timeout value in milliseconds to wait for a response after each probe packet is sent, use the command:

```
awplus(dhcp-config)# probe timeout <50-5000>
```

To specify the number of packets sent for each lease probe, use the command:

```
awplus(dhcp-config)# probe packets <0-10>
```

To disable probing for a DHCP pool, enter the configuration mode for the pool and then use the command:

```
awplus(dhcp-config)# no probe enable
```

To display the lease probe configuration settings for a specific DHCP pool or for all DHCP pools configured on the device, use the command:

```
awplus# show ip dhcp pool [<address-pool>]
```

DHCP Relay Agent Introduction

DHCP relay agents pass BOOTP messages between servers and clients. Networks where the DHCP or BOOTP server does not reside on the same IP subnet as its clients need the routers attached to the subnet to act as DHCP relay agents.

Note that both BOOTP and DHCP use BOOTP messages, allowing DHCP relay agents to relay all their packets.

Your device's DHCP Relay Agent relays these message types:

- BOOTREQUEST messages originating from any of the device's interfaces to a user-defined destination
- BOOTREPLY messages addressed to BOOTP clients on networks directly connected to the device

The relay agent ignores BOOTREPLY messages addressed to clients on networks not directly connected to the device. The device treats these as ordinary IP packets for forwarding.

A BOOTREQUEST message may be relayed via unicast, multicast or broadcast methods. In the last case, the message does not re-broadcast to the interface from which it was received. The relay destinations are configured independently of other broadcast forwarders' destinations (e.g. TFTP).

The hops field in a BOOTP message records the number of hops (routers) the message has been through. If the value of the hops field exceeds a predefined threshold, the relay agent discards the message.

Configuring the DHCP Relay Agent

To enable the DHCP relay agent on your device, use the commands:

```
awplus# configure terminal
awplus(config)# service dhcp-relay
```

You must define a relay destination on one of the device's interfaces before the relay agent can relay packets. This is the path to the DHCP server. To define a relay destination, use the commands:

```
awplus(config)# interface <interface-name>
awplus(config-if)# ip dhcp-relay server-address <ip-address>
```

You can define more than one relay destination on your device. The following table describes how the relay agent forwards the packets.

If an interface has...	Then the relay agent relays BOOTP packets it receives on that interface to...
one relay destination defined	the relay destination.
multiple relay destinations defined	each defined relay destination.

To delete a relay destination, use the command:

```
awplus(config-if)# no ip dhcp-relay server-address <ip-address>
```

See the ip dhcp-relay server-address command on page 86.20 and the service dhcp-relay command on page 86.33 for detailed command description and command examples. DHCP servers with IPv4 and IPv6 addresses can now be configured with ip dhcp-relay server-address.

When the 'hops' field in a BOOTP message exceeds a predefined threshold the BOOTP message is discarded. The default of the threshold is 10. To set the threshold, use the command:

```
awplus(config-if)# ip dhcp-relay maxhops <1-255>
```

To display the current configuration of the DHCP relay agent, use the command:

```
awplus# show ip dhcp-relay [interface <interface-name>]
```

DHCP Relay Agent Option 82

Enabling the DCHP Option 82 feature on the switch allows the switch to insert extra information into the DHCP packets that it is relaying. This information enables more accurate identification of a subscriber, as it states which switch port on which relay switch the subscriber is connected to. The information is stored in a specific optional field in the DHCP packet, namely, the agent-information field, which has option ID 82.

The DHCP relay agent inserts the Option 82 information into the DHCP packets that it is relaying to a DHCP server. DHCP servers that are configured to recognize Option 82 may use the information to implement IP addresses, or other parameter assignment policies, based on the network location of the client device. Alternatively, the server can simply log this information to create a detailed audit trail of the locations of the clients to which given addresses were allocated at given times.

If the DHCP Relay Agent Option 82 feature is enabled, the DHCP packet flow is as follows:

- The DHCP client generates a DHCP request and broadcasts it on the network.
- The DHCP relay agent intercepts the broadcast DHCP request packet and inserts the relay agent information option (Option 82) in the packet.
- The DHCP relay agent forwards the DHCP request that includes the Option 82 field to the DHCP server.
- The DHCP server receives the packet.
- If the DHCP server supports Option 82, then it echoes the Option 82 field in the DHCP reply. If the server does not support Option 82, it ignores the option and does not echo it in the reply.
- The DHCP server unicasts the reply to the relay agent.
- The relay agent removes the Option 82 field and forwards the packet to the switch port connected to the DHCP client that sent the DHCP request.

For more information about DHCP Relay Agent Option 82, see RFC 3046. Option 82 can be:

- added to packets relayed from the DHCP client to DHCP server
- removed from packets relayed from DHCP server to DHCP client
- checked from sources closer to the client

To enable the relay agent to insert its details into the Option 82 field in requests received from clients attached to a particular interface, use the command:

```
awplus(config)# interface <interface-name>
awplus(config-if)# ip dhcp-relay agent-option
```

This applies to requests received with no other agent relay information in the Option 82 field.

The Option 82 field contains sub-options. You can specify a value for the Remote ID sub-option, which contains information that identifies the host. To specify a value for the Remote ID, use the command:

```
awplus(config)# interface <interface-name>
awplus(config-if)# ip dhcp-relay agent-option remote-id
<remote-id>
```

If a Remote ID value is not specified, the Remote ID sub-option is set to the switch's MAC address.

Note that the Option 82 agent information added by DHCP Relay differs from the information inserted by the DHCP snooping (see "DHCP Option 82" on page 77.4).

Dealing with client-originated packets that already contain Option 82 information

The discussion above deals with the case where the DHCP requests arriving from the clients do not already contain Option 82 information. However, it is possible that the requests arriving from the clients to the relay agent could already contain Option 82 information. There are two main circumstances in which this can occur:

1. A client is maliciously inserting bogus information into the packet in an attempt to subvert the process of identifying the client's location

2. A Layer 2 DHCP snooping switch, that sits between the clients and the DCHP relay, is validly inserting the Option 82 information into the packets. The DHCP snooping switch is not acting as a relay agent, so it is not filling in the giaddr field (the relay IP address field) in the packet; it is only inserting the Option 82 information.

In case 1, you would want to drop the packets that contain the bogus information (or, at least remove the bogus information). In case 2, you would want to forward the valid information to the DHCP server.

To configure the switch to check for the presence of Option 82 information in incoming DHCP requests, configure DHCP-relay agent-option checking, with the command (in Interface Configuration mode):

```
awplus(config)# interface <interface-name>
awplus(config-if)# ip dhcp-relay agent-option checking
```

By default, this will cause the switch to act as follows:

- If the incoming DHCP request has a null IP address (0.0.0.0) in the giaddr field, and contains Option 82 information, drop the packet. This assumes that such a packet has been maliciously created by a client.

- If an incoming DHCP request has a non-null in the giaddr field, and contains Option 82 information, then replace the Option 82 field with the current switch's own information. This assumes that a non-null giaddr field indicates that the packet has already passed through a valid DHCP relay device, and so the presence of the Option 82 information is not an indication of malicious intent.

The action taken on packets that have a null giaddr field and an Option 82 field present cannot be altered once the agent-option check has been enabled. But the action taken on packets with a non-null giaddr field and an Option 82 field is configurable. The command to configure this action is shown below:

```
awplus(config)# interface <interface-name>
awplus(config-if)# ip dhcp-relay information policy
```

This command takes parameters that can configure the switch to:

- Leave the existing Option 82 field untouched
- Append its own Option 82 field after the existing field
- Drop the packet
- Replace the existing Option 82 information with its own (the default).

DHCP Relay Agent Option 82 maximum message length

Where a DHCP relay (that has Option 82 insertion enabled) receives a request packet from a DHCP client, it will append the Option 82 component data, and forward the packet to the DHCP server. The DHCP client will sometimes issue packets containing pad option fields that can be overwritten with Option 82 data. Where there are insufficient pad option fields to contain all the Option 82 data, the DHCP relay will increase the packet size to accommodate the Option 82 data. If the new (increased) packet size exceeds that defined by the maximum-message-length parameter, of the ip dhcp-relay max-message-length command then the DHCP relay will drop the packet.

```
awplus(config)# interface <interface-name>
awplus(config-if)# ip dhcp-relay max-message-length 1200
```

Configuring the DHCP Client

You can configure an interface on your device with a static IP address, or with a dynamic IP address assigned using your device's DHCP client. When you use the DHCP client, it obtains the IP address for the interface, and other IP configuration parameters, from a DHCP server. To configure an interface and gain its IP configuration using the DHCP client, use the command:

```
awplus(config)# interface <ifname>
awplus(config-if)# ip address dhcp [client-id <interface>]
[hostname <hostname>]
```

The DHCP client supports the following IP configuration options:

- Option 1—the subnet mask for your device.
- Option 3—a list of default routers.
- Option 6—a list of DNS servers. This list appends the DNS servers set on your device with the ip name-server command.
- Option 15—a domain name used to resolve host names. This option replaces the domain name set with the ip domain-name command. Your device ignores this domain name if it has a domain list set using the ip domain-list command.
- Option 51—lease expiration time.

If an IP interface is configured to get its IP address and subnet mask from DHCP, the interface does not take part in IP routing until the IP address and subnet mask have been set by DHCP.

For information on configuring a static IP address on an interface, see the ip address command on page 25.15.

Clearing Dynamically Allocated Lease Bindings

A lease binding is the mapping of an IP address to a physical address. To clear dynamically allocated lease bindings, use the command:

```
awplus# clear ip dhcp binding {ip <ip-address>|
        mac <mac-address>|all|pool <pool-name>|
        range <low-ip-address> <high-ip-address>}
```

You have the option to clear either a specific lease binding, specified by IP or MAC address, or to clear several lease bindings at once. The options for clearing multiple lease bindings are:

- all, to clear all DHCP bindings
- pool, to clear a specific DHCP server address pool
- range, to clear a range of DHCP clients

Command List

This chapter provides an alphabetical reference for commands used to configure DHCP. For more information, see Chapter 85, Dynamic Host Configuration Protocol (DHCP) Introduction.

For information about modifying or redirecting the output from show commands to a file, see "Controlling "show" Command Output" on page 1.41.

bootfile

This command sets the boot filename for a DHCP server pool. This is the name of the boot file that the client should use in its bootstrap process. It may need to include a path.

The no variant of this command removes the boot filename from a DHCP server pool.

Syntax

```
bootfile <filename>
no bootfile
```

Parameter	Description
<filename>	The boot file name.

Mode DHCP Configuration

Example To configure the boot filename for a pool P2, use the command:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# bootfile boot/main_boot.bt
```

clear ip dhcp binding

This command clears either a specific lease binding or the lease bindings specified by the command. The command will only take effect on dynamically allocated bindings, not statically configured bindings.

Syntax

```
clear ip dhcp binding {ip <ip-address>|mac <mac-address>|all|pool
   <pool-name>|range <low-ip-address> <high-ip-address>}
```

Parameter	Description
`ip <ip-address>`	IPv4 address of the DHCP client, in dotted decimal notation in the format A.B.C.D.
`mac <mac-address>`	MAC address of the DHCP client, in hexadecimal notation in the format HHHH.HHHH.HHHH.
`all`	All DHCP bindings.
`pool <pool-name>`	Description used to identify DHCP server address pool. Valid characters are any printable character. If the name contains spaces then you must enclose these in “quotation marks”.
`range <low-ip-address> <high-ip-address>`	IPv4 address range for DHCP clients, in dotted decimal notation. The first IP address is the low end of the range, the second IP address is the high end of the range.

Mode Privileged Exec

Usage A specific binding may be deleted by ip address or mac address, or several bindings may be deleted at once using all, pool or range.

Note that if you specify to clear the ip or mac address of what is actually a static DHCP binding, an error message is displayed. If all, pool or range are specified and one or more static DHCP bindings exist within those addresses, any dynamic entries within those addresses are cleared but any static entries are not cleared.

Examples To clear the specific IP address binding `192.168.1.1`, use the command:

```
awplus# clear ip dhcp binding ip 192.168.1.1
```

To clear all dynamic DHCP entries, use the command:

```
awplus# clear ip dhcp binding all
```

Related Commands show ip dhcp binding

default-router

This command adds a default router to the DHCP address pool you are configuring. You can use this command multiple times to create a list of default routers on the client's subnet. This sets the router details using the pre-defined option 3. Note that if you add a user-defined option 3 using the option command, then you will override any settings created with this command.

The no variant of this command removes either the specified default router, or all default routers from the DHCP pool.

Syntax

```
default-router <ip-address>
no default-router [<ip-address>]
```

Parameter	Description
<ip-address>	IPv4 address of the default router, in dotted decimal notation.

Mode DHCP Configuration

Examples To add a router with an IP address 192.168.1.2 to the DHCP pool named P2, use the following commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# default-router 192.168.1.2
```

To remove a router with an IP address 192.168.1.2 to the DHCP pool named P2, use the following commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no default-router 192.168.1.2
```

To remove all routers from the DHCP pool named P2, use the following commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no default-router
```

dns-server

This command adds a Domain Name System (DNS) server to the DHCP address pool you are configuring. You can use this command multiple times to create a list of DNS name servers available to the client. This sets the DNS server details using the pre-defined option 6. Note that if you add a user-defined option 6 using the option command on page 86.26, then you will override any settings created with this command.

The no variant of this command removes either the specified DNS server, or all DNS servers from the DHCP pool.

Syntax

```
dns-server <ip-address>
no dns-server [<ip-address>]
```

Parameter	Description
<ip-address>	IPv4 address of the DNS server, in dotted decimal notation.

Mode DHCP Configuration

Examples To add the DNS server with the assigned IP address 192.168.1.1 to the DHCP pool named P1, use the following commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# dns-server 192.168.1.1
```

To remove the DNS server with the assigned IP address 192.168.1.1 from the DHCP pool named P1, use the following commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no dns-server 192.168.1.1
```

To remove all DNS servers from the DHCP pool named P1, use the following commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no dns-server
```

Related Commands

default-router
option
service dhcp-server
show ip dhcp pool
subnet-mask

domain-name

This command adds a domain name to the DHCP address pool you are configuring. Use this command to specify the domain name that a client should use when resolving host names using the Domain Name System. This sets the domain name details using the pre-defined option 15. Note that if you add a user-defined option 15 using the option command on page 86.26, then you will override any settings created with this command.

The no variant of this command removes the domain name from the address pool.

Syntax

```
domain-name <domain-name>
no domain-name
```

Parameter	Description
<domain-name>	The domain name you wish to assign the DHCP pool. Valid characters are any printable character. If the name contains spaces then you must enclose it in “quotation marks”.

Mode DHCP Configuration

Examples To add the domain name `Nerv_Office` to DHCP pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# domain-name Nerv_Office
```

To remove the domain name `Nerv_Office` from DHCP pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no domain-name Nerv_Office
```

Related Commands

dns-server
option
service dhcp-server
show ip dhcp pool
subnet-mask

host

This command adds a static host address to the DHCP address pool you are configuring. The client with the matching MAC address is permanently assigned this IP address. No other clients can request it.

The no variant of this command removes the specified host address from the DHCP pool. Use the no host all command to remove all static host addresses from the DHCP pool.

Syntax

```
host <ip-address> <mac-address>
no host <ip-address>
no host all
```

Parameter	Description
<ip-address>	IPv4 address of the DHCP client, in dotted decimal notation in the format A.B.C.D
<mac-address>	MAC address of the DHCP client, in hexadecimal notation in the format HHHH.HHHH.HHHH

Mode DHCP Configuration

Usage Note that a network/mask must be configured using a network command before issuing a host command. Also note that a host address must match a network to add a static host address.

Examples To add the host at `192.168.1.5` with the MAC address `000a.451d.6e34` to DHCP pool `1`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool 1
awplus(dhcp-config)# network 192.168.1.0/24
awplus(dhcp-config)# host 192.168.1.5 000a.451d.6e34
```

To remove the host at `192.168.1.5` with the MAC address `000a.451d.6e34` from DHCP pool `1`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool 1
awplus(dhcp-config)# no host 192.168.1.5 000a.451d.6e34
```

Related Commands
lease
range
show ip dhcp pool

ip address dhcp

This command activates the DHCP client on the interface you are configuring. This allows the interface to use the DHCP client to obtain its IP configuration details from a DHCP server on its connected network.

The client-id and hostname parameters are identifiers that you may want to set in order to interoperate with your existing DHCP infrastructure. If neither option is needed, then the DHCP server uses the MAC address field of the request to identify the host.

The DHCP client supports the following IP configuration options:

- Option 1 - the subnet mask for your device.
- Option 3 - a list of default routers.
- Option 6 - a list of DNS servers. This list appends the DNS servers set on your device with the ip name-server command.
- Option 15 - a domain name used to resolve host names. This option replaces the domain name set with the ip domain-name command. Your device ignores this domain name if it has a domain list set using the ip domain-list command.
- Option 51 - lease expiration time.

The no variant of this command stops the interface from obtaining IP configuration details from a DHCP server.

Syntax

```
ip address dhcp [client-id <interface>] [hostname <hostname>]
no ip address dhcp
```

Parameter	Description
<interface>	The name of the interface you are activating the DHCP client on. If you specify this, then the MAC address associated with the specified interface is sent to the DHCP server in the optional identifier field. Default: no default
<hostname>	The hostname for the DHCP client on this interface. Typically this name is provided by the ISP. Default: no default

Mode Interface Configuration for a VLAN interface.

Examples To set the interface `vlan10` to use DHCP to obtain an IP address, use the command:

```
awplus# configure terminal
awplus(config)# interface vlan10
awplus(config-if)# ip address dhcp
```

To stop the interface `vlan10` from using DHCP to obtain its IP address, use the command:

```
awplus# configure terminal
awplus(config)# interface vlan10
awplus(config-if)# no ip address dhcp
```

Related Commands ip address

Validation Commands show running-config
show running-config access-list

ip dhcp bootp ignore

This command configures the DHCP server to ignore any BOOTP requests it receives. The DHCP server accepts BOOTP requests by default.

The no variant of this command configures the DHCP server to accept BOOTP requests. This is the default setting.

Syntax

```
ip dhcp bootp ignore
no ip dhcp bootp ignore
```

Mode Global Configuration

Examples To configure the DHCP server to ignore BOOTP requests, use the command:

```
awplus# configure terminal
awplus(config)# ip dhcp bootp ignore
```

To configure the DHCP server to respond to BOOTP requests, use the command:

```
awplus# configure terminal
awplus(config)# no ip dhcp bootp ignore
```

Related Commands show ip dhcp server summary

ip dhcp leasequery enable

Use this command to enable the DHCP server to respond to DHCPLEASEQUERY packets. Enabling the DHCP leasequery feature allows a DHCP relay agent to obtain IP address information directly from the DHCP server using DHCPLEASEQUERY messages.

Use the no variant of this command to disable the support of DHCPLEASEQUERY packets.

For more information, see "Enable DHCP Leasequery" on page 85.5.

Syntax

```
ip dhcp leasequery enable
no ip dhcp leasequery enable
```

Default DHCP leasequery support is disabled by default.

Mode Global Configuration

Examples To enable DHCP leasequery support, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp leasequery enable
```

To disable DHCP leasequery support, use the commands:

```
awplus# configure terminal
awplus(config)# no ip dhcp leasequery enable
```

Related Commands

show counter dhcp-server
show ip dhcp server statistics
show ip dhcp server summary

ip dhcp option

This command creates a user-defined DHCP option. You can then use this option when configuring a DHCP pool, by using the option command. Options with the same number as one of the pre-defined options override the standard option definition. The pre-defined options use the option numbers 1, 3, 6, 15, and 51.

The no variant of this command removes either the specified user-defined option, or removes all user-defined options. This also automatically removes the user-defined options from the associated DHCP address pools.

Syntax

```
ip dhcp option <1-254> [name <option-name>] [<option-type>]
no ip dhcp option [<1-254>|<option-name>]
```

Parameter	Description	
<1-254>	The option number of the option. Options with the same number as one of the standard options overrides the standard option definition.	
<option-name>	Option name used to identify the option. You cannot use a number as the option name. Valid characters are any printable character. If the name contains spaces then you must enclose it in “quotation marks”. Default: no default	
<option-type>	The option value. You must specify a value that is appropriate to the option type:	
	`asci`	An ASCII text string
	`hex`	A hexadecimal string. Valid characters are the numbers 0–9 and letters a–f. Embedded spaces are not valid. The string must be an even number of characters, from 2 and 256 characters long.
	`ip`	An IPv4 address or mask that has the dotted decimal A.B.C.D notation. To create a list of IP addresses, you must add each IP address individually by using the option command multiple times.
	`integer`	A number from 0 to 4294967295.
	`flag`	A value that either sets (to 1) or unsets (to 0) a flag: true, on, or enabled will set the flag false, off or disabled will unset the flag.

Mode Global Configuration

Examples To define a user-defined ASCII string option as option 66, without a name, use the command:

```
awplus# configure terminal
awplus(config)# ip dhcp option 66 ascii
```

To define a user-defined hexadecimal string option as option 46, with the name “tcpip-node-type”, use the command:

```
awplus# configure terminal
awplus(config)# ip dhcp option 46 name tcpip-node-type hex
```

To define a user-defined IP address option as option 175, with the name `special-address`, use the command:

```
awplus# configure terminal
awplus(config)# ip dhcp option 175 name special-address ip
```

To remove the specific user-defined option with the option number `12`, use the command:

```
awplus# configure terminal
awplus(config)# no ip dhcp option 12
```

To remove the specific user-defined option with the option name `perform-router-discovery`, use the command:

```
awplus# configure terminal
awplus(config)# no ip dhcp option perform-router-discovery
```

To remove all user-defined option definitions, use the command:

```
awplus# configure terminal
awplus(config)# no ip dhcp option
```

dns-server
domain-name
option
service dhcp-server
show ip dhcp server summary
subnet-mask

ip dhcp pool

This command will enter the configuration mode for the pool name specified. If the name specified is not associated with an existing pool, the switch will create a new pool with this name, then enter the configuration mode for the new pool.

Once you have entered the DHCP configuration mode, all commands executed before the next exit command will apply to this pool.

You can create multiple DHCP pools on devices with multiple interfaces. This allows the device to act as a DHCP server on multiple interfaces to distribute different information to clients on the different networks.

The no variant of this command deletes the specific DHCP pool.

Syntax

```
ip dhcp pool <pool-name>
no ip dhcp pool <pool-name>
```

Parameter	Description
<pool-name>	Description used to identify this DHCP pool. Valid characters are any printable character. If the name contains spaces then you must enclose it in “quotation marks”.

Mode Global Configuration

Example To create the DHCP pool called `P2`, use the command:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
```

Related Commands service dhcp-server

ip dhcp-relay agent-option

This command enables the DHCP relay agent to insert the relay agent information option (Option 82) into the client-request packets that it relays to its DHCP server. This allows the relay agent to pass on information to the server about the network location of the client device. The relay agent then strips the Option 82 field out of the server's response, so that the client never sees this field.

When the relay agent appends its Option 82 data into the packet, it first overwrites any pad options present; then if necessary, it increases the packet length to accommodate the option-82 data.

The no variant of this command stops the relay agent from appending the Option 82 field onto DHCP requests before forwarding it to the server.

Syntax

```
ip dhcp-relay agent-option

no ip dhcp-relay agent-option
```

Default The DHCP relay agent feature is disabled by default.

Mode Interface Configuration for a VLAN interface.

Usage Use this command to alter the relay agent's Option 82 setting when your device is the first hop for the DHCP client. To limit the maximum length of the packet, use the ip dhcp-relay max-message-length command.

This command cannot be enabled if DHCP snooping is enabled (service dhcp-snooping command on page 78.24), and vice versa.

Examples To make the relay agent listening on `vlan15` append the Option 82 field, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan15
awplus(config-if)# ip dhcp-relay agent-option
```

To stop the relay agent from appending the Option 82 field on `vlan15`, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan15
awplus(config-if)# no ip dhcp-relay agent-option
```

Related Commands

ip dhcp-relay agent-option remote-id
ip dhcp-relay information policy
ip dhcp-relay max-message-length
service dhcp-relay

ip dhcp-relay agent-option checking

This command controls the way that the DHCP-relay service deals with packets arriving from the client side that have:

- Option 82 information present in the packet
- a giaddr field (relay agent IP address field) of 0.0.0.0

By default such packets are accepted and passed through. This assumes that the Option 82 field has been inserted into the packet by a trusted device, such as a Layer 2 DHCP-snooping switch.

However, if you do not have such a trusted device between the relay switch and the clients, then packets arriving with no relay address but containing Option 82 information are treated with suspicion and dropped.

The command ip dhcp-relay agent-option checking will cause such packets to be dropped. Packets which contain Option 82 information, but have a non-zero address in the giaddr field will continue to be forwarded.

The no variant of this command returns this feature to the default state, whereby the DHCP-relay service does not check the state of the giaddr field in packets that contain Option 82 information.

Note The DHCP-relay service might also alter the content of the Option 82 field, if the commands ip dhcp-relay agent-option and ip dhcp-relay information policy have also been configured.

Syntax

```
ip dhcp-relay agent-option checking
no ip dhcp-relay agent-option checking
```

Mode Interface Configuration for a VLAN interface.

Examples To make the relay agent listening on `vlan10` check the Agent ID sub-option field, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan10
awplus(config-if)# ip dhcp-relay agent-option checking
```

To stop the relay agent on `vlan10` from checking the Agent ID sub-option field, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan10
awplus(config-if)# no ip dhcp-relay agent-option checking
```

Related Commands ip dhcp-relay agent-option remote-id
service dhcp-relay

ip dhcp-relay agent-option remote-id

Use this command to specify the Remote ID sub-option of the Option 82 field the DHCP relay agent inserts into clients' request packets. The Remote ID identifies the device that is inserting the Option 82 information. If a Remote ID is not specified, the Remote ID sub-option is set to the switch's MAC address.

Use the no variant of this command to return the Remote ID for an interface.

Syntax

```
ip dhcp-relay agent-option remote-id <remote-id>
no ip dhcp-relay agent-option remote-id
```

Parameter	Description
<remote-id>	An alphanumeric (ASCII) string, 1 to 63 characters in length. Additional characters allowed are hyphen (-), underscore (_) and hash (#). Spaces are not allowed.

Default The Remote ID is set to the switch's MAC address by default.

Mode Interface Configuration for a VLAN interface.

Usage The Remote ID sub-option is included in the DHCP Option 82 field of relayed client DHCP packets if:

- DHCP Option 82 is enabled (ip dhcp-relay agent-option), and
- DHCP relay agent is enabled on the switch (service dhcp-relay)

Examples To set the Remote ID to `myid` for client DHCP packets received on `vlan1`, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan1
awplus(config-if)# ip dhcp-relay agent-option remote-id myid
```

To remove the Remote ID specified for `vlan1`, use the commands:

```
awplus# configure terminal
awplus(config)# interface vlan1
awplus(config-if)# no ip dhcp-relay agent-option remote-id
```

Related Commands
ip dhcp-relay agent-option
ip dhcp-relay agent-option checking
show ip dhcp-relay

ip dhcp-relay information policy

This command sets the policy for how the DHCP relay deals with packets arriving from the client that contain Option 82 information.

If the command ip dhcp-relay agent-option has not been configured, then this command has no effect at all - no alteration is made to Option 82 information in packets arriving from the client side.

However, if the command ip dhcp-relay agent-option has been configured, this command modifies how the DHCP relay service deals with cases where the packet arriving from the client side already contains Option 82 information.

By default, the relay agent replaces any existing Option 82 field with its own relay agent field. This is equivalent to the functionality of the replace parameter.

The no variant of this command removes the policy, and returns it to the default behavior - i.e. replacing the existing Option 82 field.

Syntax

```
ip dhcp-relay information policy [append|drop|keep|replace]
no ip dhcp-relay information policy
```

Parameter	Description
`append`	The relay agent appends the Option 82 field of the packet with its own Option 82 details.
`drop`	The relay agent discards the packet.
`keep`	The relay agent forwards the packet without altering the Option 82 field.
`replace`	The relay agent replaces the existing relay agent details in the Option 82 field with its own details before forwarding the packet.

Mode Interface Configuration for a VLAN interface.

Examples To make the relay agent listening on `vlan15` drop any client requests that already contain Option 82 information, use the command:

```
awplus(config)# interface vlan15
awplus(config-if)# ip dhcp-relay information policy drop
```

To remove the DHCP relay information policy set with the ip dhcp information policy command, use the command:

```
awplus(config)# interface vlan15
awplus(config-if)# no ip dhcp-relay information policy
```

Related Commands ip dhcp-relay agent-option
service dhcp-server

ip dhcp-relay maxhops

This command sets the hop count threshold for discarding BOOTP messages. When the hops field in a BOOTP message exceeds the threshold, the relay agent discards the BOOTP message. The hop count threshold is set to 10 hops by default.

Use the no variant of this command negation command to reset the hop count to the default.

Syntax

```
ip dhcp-relay maxhops <1-255>
no ip dhcp-relay maxhops
```

Parameter	Description
<1-255>	The maximum hop count value.

Default The default hop count threshold is 10 hops.

Mode Interface Configuration for a VLAN interface.

Example To set the maximum number of hops to 5 for packets arriving in interface `vlan15`, use the command:

```
awplus(config)# interface vlan15
awplus(config-if)# ip dhcp-relay maxhops 5
```

Related Commands service dhcp-relay

ip dhcp-relay max-message-length

This command applies when the switch is acting as a DHCP relay and Option 82 insertion is enabled. It sets the maximum DHCP message length (in bytes) for the DHCP packet with its Option 82 data inserted. From this value it calculates the maximum packet size that it will accept at its input. Packets that arrive greater than this value will be dropped.

The no variant of this command sets the maximum message length to its default of 1400 bytes.

Syntax

```
ip dhcp-relay max-message-length <548-1472>
no ip dhcp-relay max-message-length
```

Parameter	Description
<548-1472>	The maximum DHCP message length (this is the message header plus the inserted DHCP option fields).

Default The default is 1400 bytes.

Mode Interface Configuration for a VLAN interface.

Usage Where a DHCP relay (that has Option 82 insertion enabled) receives a *request* packet from a DHCP client, it will append the Option 82 component data, and forward the packet to the DHCP server. The DHCP client will sometimes issue packets containing pad option fields that can be overwritten with Option 82 data. Where there are insufficient pad option fields to contain all the Option 82 data, the DHCP relay will increase the packet size to accommodate the Option 82 data. If the new (increased) packet size exceeds that defined by the maximum-message-length parameter, then the DHCP relay will drop the packet.

Note

Before setting this command, you must first run the ip dhcp-relay agent-option command on page 86.14. This will allow the Option 82 fields to be appended.

Example To set the maximum DHCP message length to 1200 for packets arriving in interface `vlan7`, use the command:

```
awplus# configure terminal
awplus(config)# interface vlan7
awplus(config-if)# ip dhcp-relay max-message-length 1200
```

To reset the maximum DHCP message length to the default of 1400 for packets arriving in interface `vlan7`, use the command:

```
awplus# configure terminal
awplus(config)# interface vlan7
awplus(config-if)# no ip dhcp-relay max-message-length
```

Related Commands service dhcp-relay

ip dhcp-relay server-address

This command adds a DHCP server for the DHCP relay agent to forward client DHCP packets to on a particular interface. You can add up to five DHCP servers on each device interface that the DHCP relay agent is listening on.

The no variant of this command deletes the specified DHCP server from the list of servers available to the DHCP relay agent.

For introduction and configuration information about DHCP relay agent see "DHCP Relay Agent Introduction" on page 85.8 and "Configuring the DHCP Relay Agent" on page 85.8.

Syntax

```
ip dhcp-relay server-address {<ipv4-address>|
    <ipv6-address> <server-interface>}

no ip dhcp-relay server-address {<ip-address>|
    <ipv6-address> <server-interface>}
```

Parameter	Description
<ipv4-address>	Specify the IPv4 address of the DHCP server for DHCP relay agent to forward client DHCP packets to, in dotted decimal notation. The IPv4 address uses the format A.B.C.D.
<ipv6-address>	Specify the IPv6 address of the DHCP server for DHCP relay agent to forward client DHCP packets to, in hexadecimal notation.
<server-interface>	Specify the interface name of the DHCP server itself, not the interface of the device as specified in Interface Configuration. The interface name of the DHCP server is only required for a DHCP server with an IPv6 address not with an IPv4 address.

Mode Interface Configuration for a VLAN interface.

Usage For a DHCP server with an IPv6 address you must specify the interface for the DHCP server. See examples below for configuration differences between IPv4 and IPv6 DHCP relay servers.

See also the service dhcp-relay command to enable the DHCP relay agent on your device. The ip dhcp-relay server-address command defines a relay destination on an interface on the device, needed before the DHCP relay agent relays DHCP client packets from a DHCP server.

Examples To enable the DHCP relay agent to relay DHCP packets on interface `vlan2` to the DHCP server with the IPv4 address `192.0.2.200`, use the following command sequence:

```
awplus# configure terminal
awplus(config)# service dhcp-relay
awplus(config)# interface vlan2
awplus(config-if)# ip dhcp-relay server-address 192.0.2.200
```

To remove the DHCP server with the IPv4 address `192.0.2.200` from the list of servers available to the DHCP relay agent on interface `vlan2`, use the following command sequence:

```
awplus# configure terminal
awplus(config)# interface vlan2
awplus(config-if)# no ip dhcp-relay server-address 192.0.2.200
```

To enable the DHCP relay agent on your device to relay DHCP packets on interface `vlan10` to the DHCP server with the IPv6 address `2001:0db8:010d::1` on interface `vlan20`, use the following command sequence:

```
awplus# configure terminal
awplus(config)# service dhcp-relay
awplus(config)# interface vlan10
awplus(config-if)# ip dhcp-relay server-address
2001:0db8:010d::1 vlan20
```

To remove the DHCP server with the IPv6 address `2001:0db8:010d::1` on interface `vlan20` from the list of servers available to the DHCP relay agent on interface `vlan10`, use the following command sequence:

```
awplus# configure terminal
awplus(config)# interface vlan10
awplus(config-if)# no ip dhcp-relay server-address
2001:0db8:010d::1 vlan20
```

Related Commands service dhcp-relay

lease

This command sets the expiration time for a leased address for the DHCP address pool you are configuring. The time set by the days, hours, minutes and seconds is cumulative. The minimum total lease time that can be configured is 20 seconds. The maximum total lease time that can be configured is 120 days.

Note that if you add a user-defined option 51 using the option command, then you will override any settings created with this command. Option 51 specifies a lease time of 1 day.

Use the infinite parameter to set the lease expiry time to infinite (leases never expire).

Use the no variant of this command to return the lease expiration time back to the default of one day.

Syntax

```
lease <days> <hours> <minutes> [<seconds>]
lease infinite
no lease
```

Parameter	Description
<days>	The number of days, from 0 to 120, that the lease expiry time is configured for. Default: 1
<hours>	The number of hours, from 0 to 24, that the lease expiry time is configured for. Default: 0
<minutes>	The number of minutes, from 0 to 60, the lease expiry time is configured for. Default: 0
<seconds>	The number of seconds, from 0 to 60, the lease expiry time is configured for.
`infinite`	The lease never expires.

Default The default lease time is 1 day.

Mode DHCP Configuration

Examples To set the lease expiration time for address pool `P2` to 35 minutes, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# lease 0 0 35
```

To set the lease expiration time for the address pool `Nerv_Office` to 1 day, 5 hours, and 30 minutes, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool Nerv_Office
awplus(dhcp-config)# lease 1 5 30
```

To set the lease expiration time for the address pool `P3` to 20 seconds, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P3
awplus(dhcp-config)# lease 0 0 0 20
```

To set the lease expiration time for the pool to never expire, use the command:

```
awplus(dhcp-config)# lease infinite
```

To return the lease expiration time to the default of one day, use the command:

```
awplus(dhcp-config)# no lease
```

Related Commands

option
service dhcp-server

network (DHCP)

This command sets the network (subnet) that the DHCP address pool applies to.

The no variant of this command removes the network (subnet) from the DHCP address pool.

Syntax

```
network {<ip-subnet-address/prefix-length>|<ip-subnet-address/mask>}
no network
```

Parameter	Description
<ip-subnet-address/prefix-length>	The IPv4 subnet address in dotted decimal notation followed by the prefix length in slash notation.
<ip-subnet-address/mask>	The IPv4 subnet address in dotted decimal notation followed by the subnet mask in dotted decimal notation.

Mode DHCP Configuration

Usage This command will fail if it would make existing ranges invalid. For example, if they do not lie within the new network you are configuring.

The no variant of this command will fail if ranges still exist in the pool. You must remove all ranges in the pool before issuing a no network command to remove a network from the pool.

Examples To configure a network for the address pool `P2`, where the subnet is `192.0.2.5` and the mask is `255.255.255.0`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# network 192.0.2.5/24
```

or you can use dotted decimal notation instead of slash notation for the subnet-mask:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# network 192.0.2.5 255.255.255.0
```

Related Commands service dhcp-server
subnet-mask

next-server

This command sets the next server address for a DHCP server pool. It is the address of the next server that the client should use in its bootstrap process.

The no variant of this command removes the next server address from the DHCP address pool.

Syntax

```
next-server <ip-address>
no next-server
```

Parameter	Description
<ip-address>	The server IP address, entered in dotted decimal notation.

Mode DHCP Configuration

Example To set the next-server address for the address pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# next-server 192.0.2.2
```

option

This command adds a user-defined option to the DHCP address pool you are configuring. For the hex, integer, and flag option types, if the option already exists, the new option overwrites the existing option's value. Options with an ip type can hold a list of IP addresses or masks (i.e. entries that have the A.B.C.D address format), so if the option already exists in the pool, then the new IP address is added to the list of existing IP addresses.

Options with the same number as one of the pre-defined options override the standard option definition. The pre-defined options use the option numbers 1, 3, 6, 15, and 51.

The no variant of this command removes the specified user-defined option from the DHCP pool, or all user-defined options from the DHCP pool.

Syntax

```
option [<1-254>|<option-name>] <option-value>
no option [<1-254>|<option-value>]
```

Parameter	Description	
<1-254>	The option number of the option. Options with the same number as one of the standard options overrides the standard option definition.	
<option-name>	Option name associated with the option.	
<option-value>	The option value. You must specify a value that is appropriate to the option type:	
	`hex`	A hexadecimal string. Valid characters are the numbers 0–9 and letters a–f. Embedded spaces are not valid. The string must be an even number of characters, from 2 and 256 characters long.
	`ip`	An IPv4 address or mask that has the dotted decimal A.B.C.D notation. To create a list of IP addresses, you must add each IP address individually using the option command multiple times.
	`integer`	A number from 0 to 4294967295.
	`flag`	A value of either true, on, or enabled to set the flag, or false, off or disabled to unset the flag.

Mode DHCP Configuration

Examples To add the ASCII-type option named `tftp-server-name` to the pool `P2` and give the option the value `server1`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# option tftp-server-name server1
```

To add the hex-type option named `tcpip-node-type` to the pool `P2` and give the option the value `08af`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# option tcpip-node-type 08af
```

To add multiple IP addresses for the ip-type option `175`, use the command:

```
awplus(dhcp-config)# option 175 192.0.2.6
awplus(dhcp-config)# option 175 192.0.2.12
awplus(dhcp-config)# option 175 192.0.2.33
```

To add the option `179` to a pool, and give the option the value `123456`, use the command:

```
awplus(dhcp-config)# option 179 123456
```

To add a user-defined flag option with the name `perform-router-discovery`, use the command:

```
awplus(dhcp-config)# option perform-router-discovery yes
```

To clear all user-defined options from a DHCP address pool, use the command:

```
awplus(dhcp-config)# no option
```

To clear a user-defined option, named `tftp-server-name`, use the command:

```
awplus(dhcp-config)# no option tftp-server-name
```

Related Commands

ip dhcp option
lease
service dhcp-server

probe enable

Use this command to enable lease probing for a DHCP pool. Probing is used by the DHCP server to check if an IP address it wants to lease to a client is already being used by another host.

The no variant of this command disables probing for a DHCP pool.

Syntax

```
probe enable
no probe enable
```

Default Probing is enabled by default.

Mode DHCP Pool Configuration

Examples To enable probing for pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(config-if)# probe enable
```

To disable probing for pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no probe enable
```

Related Commands

ip dhcp pool
probe packets
probe timeout
probe type
show ip dhcp pool

probe packets

Use this command to specify the number of packets sent for each lease probe. Lease probing is configured on a per-DHCP pool basis. When set to 0 probing is effectively disabled.

The no variant of this command sets the number of probe packets sent to the default of 5.

Syntax

```
probe packets <0-10>
no probe packets
```

Parameter	Description
<0-10>	The number of probe packets sent.

Default The default is 5.

Mode DHCP Pool Configuration

Examples To set the number of probe packets to 2 for pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# probe packets 2
```

To set the number of probe packets to the default 5 for pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no probe packets
```

Related Commands

probe enable
probe timeout
probe type
show ip dhcp pool

probe timeout

Use this command to set the timeout value in milliseconds that the server waits for a response after each probe packet is sent. Lease probing is configured on a per-DHCP pool basis.

The no variant of this command sets the probe timeout value to the default setting, 200 milliseconds.

Syntax

```
probe timeout <50-5000>
no probe timeout
```

Parameter	Description
<50-5000>	Timeout interval in milliseconds.

Default The default timeout interval is 200 milliseconds.

Mode DHCP Pool Configuration

Examples To set the probe timeout value to 500 milliseconds for pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# probe timeout 500
```

To set the probe timeout value for pool `P2` to the default, 200 milliseconds, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no probe timeout
```

Related Commands

probe enable
probe packets
probe type
show ip dhcp pool

probe type

Use this command to set the probe type for a DHCP pool. The probe type specifies how the DHCP server checks whether an IP address is being used by other hosts, referred to as lease probing. If arp is specified, the server sends an ARP request to determine if an address is in use. If ping is specified, the server will send an ICMP Echo Request (ping).

The no variant of this command sets the probe type to the default setting, ping.

Syntax

```
probe type {arp|ping}
no probe type
```

Parameter	Description
arp	Probe using ARP.
ping	Probe using ping.

Default The default probe type is ping.

Mode DHCP Pool Configuration

Examples To set the probe type to `arp` for the pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# probe type arp
```

To set the probe type for the pool `P2` to the default, `ping`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no probe type
```

Related Commands

ip dhcp pooll

range

This command adds an address range to the DHCP address pool you are configuring. The DHCP server responds to client requests received from the pool's network. It assigns an IP addresses within the specified range. The IP address range must lie within the network. You can add multiple address ranges and individual IP addresses for a DHCP pool by using this command multiple times.

The no variant of this command removes an address range from the DHCP pool. Use the no range all command to remove all address ranges from the DHCP pool.

Syntax

```
range <ip-address> [<ip-address>]
no range <ip-address> [<ip-address>]
no range all
```

Parameter	Description
<ip-address>	IPv4 address range for DHCP clients, in dotted decimal notation. The first IP address is the low end of the range, the second IP address is the high end. Specify only one IP address to add an individual IP address to the address pool.

Mode DHCP Configuration

Examples To add an address range of `192.0.2.5` to `192.0.2.16` to the pool `Nerv_Office`, use the command:

```
awplus# configure terminal
awplus(config)# ip dhcp pool Nerv_Office
awplus(dhcp-config)# range 192.0.2.5 192.0.2.16
```

To add the individual IP address `192.0.2.2` to a pool, use the command:

```
awplus(dhcp-config)# range 192.0.2.2
```

To remove all address ranges from a pool, use the command:

```
awplus(dhcp-config)# no range all
```

Related Commands
ip dhcp pool
service dhcp-server
show ip dhcp pool

service dhcp-relay

This command enables the DHCP relay agent on the device. However, on a given IP interface, no DHCP forwarding takes place until at least one DHCP server is specified to forward/relay all clients' DHCP packets to.

The no variant of this command disables the DHCP relay agent on the device for all interfaces.

Syntax

```
service dhcp-relay
no service dhcp-relay
```

Mode Global Configuration

Usage A maximum number of 400 DHCP relay agents (one per interface) can be configured on the device. Once this limit has been reached, any further attempts to configure DHCP relay agents will not be successful.

Default The DHCP-relay service is enabled by default.

Examples To enable the DHCP relay global function, use the command:

```
awplus# configure terminal
awplus(config)# service dhcp-relay
```

To disable the DHCP relay global function, use the command:

```
awplus# configure terminal
awplus(config)# no service dhcp-relay
```

Related Commands

ip dhcp-relay maxhops
ip dhcp-relay server-address

service dhcp-server

This command enables the DHCP server on your device. The server then listens for DHCP requests on all IP interfaces. It will not run if there are no IP interfaces configured.

The no variant of this command disables the DHCP server.

Syntax

```
service dhcp-server
no service dhcp-server
```

Mode Global Configuration

Example To enable the DHCP server, use the command:

```
awplus# configure terminal
awplus(config)# service dhcp-server
```

Table 86-2: Parameters in the output of the **show counter dhcp-relay** command

Parameter	Description
`Requests In`	The number of DHCP Request messages received from clients.
`Replies In`	The number of DHCP Reply messages received from servers.
`Relayed To Server`	The number of DHCP Request messages relayed to servers.
`Relayed To Client`	The number of DHCP Reply messages relayed to clients.
`Out To Server Failed`	The number of failures when attempting to send request messages to servers. This is an internal debugging counter.
`Out To Client Failed`	The number of failures when attempting to send reply messages to clients. This is an internal debugging counter.
`Invalid hlen`	The number of incoming messages dropped due to an invalid hlen field.
`Bogus giaddr`	The number of incoming DHCP Reply messages dropped due to bogus giaddr field.
`Corrupt Agent Option`	The number of incoming DHCP Reply messages dropped due to corrupt agent option.
`Missing Agent Option`	The number of incoming DHCP Reply messages dropped due to missing agent option.

Table 86-2: Parameters in the output of the **show counter dhcp-relay** command(cont.)

Parameter	Description
`Bad Circuit ID`	The number of incoming DHCP Reply messages dropped due to bad circuit ID.
`Missing Circuit ID`	The number of incoming DHCP Reply messages dropped due to missing circuit ID.
`Option Insert Failed`	The number of incoming DHCP Request messages dropped due to an error adding the relay agent information (option-82). This counter increments when: the relay agent is set to drop packets with the Option 82 field already filled by another relay agent. This policy is set with the ip dhcp-relay information policy command. there is a packet error that stops the relay agent from being able to append the packet with its relay agent option information.

Related Commands

service dhcp-relay
show ip dhcp-relay

show counter dhcp-server

This command shows counters for the DHCP server on your device.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show counter dhcp-server`

Mode User Exec and Privileged Exec

Example To display counters for the DHCP server on your device, use the command:

```
awplus# show counter dhcp-server
```

Output Figure 86-3: Example output from the **show counter dhcp-server** command

```
DHCP server counters
DHCPDISCOVER in       ......... 20
DHCPREQUEST in        ......... 12
DHCPDECLINE in        ......... 1
DHCPRELEASE in        ......... 0
DHCPINFORM in         ......... 0
DHCPOFFER out         ......... 8
DHCPACK out           ......... 4
DHCPNAK out           ......... 0
BOOTREQUEST in        ......... 0
BOOTREPLY out         ......... 0
DHCPLEASEQUERY in       ....... 0
DHCPLEASEUNKNOWN out    ....... 0
DHCPLEASEACTIVE out     ....... 0
DHCPLEASEUNASSIGNED out ....... 0
```

Table 86-3: Parameters in the output of the **show counter dhcp-server** command

Parameter	Description
DHCPDISCOVER in	The number of Discover messages received by the DHCP server.
DHCPREQUEST in	The number of Request messages received by the DHCP server.
DHCPDECLINE in	The number of Decline messages received by the DHCP server.
DHCPRELEASE in	The number of Release messages received by the DHCP server.
DHCPINFORM in	The number of Inform messages received by the DHCP server.
DHCPOFFER out	The number of Offer messages sent by the DHCP server.
DHCPACK out	The number of Acknowledgement messages sent by the DHCP server.
DHCPNAK out	The number of Negative Acknowledgement messages sent by the DHCP server. The server sends these after receiving a request that it cannot fulfil because either there are no available IP addresses in the related address pool, or the request has come from a client that doesn't fit the network setting for an address pool.

Table 86-3: Parameters in the output of the **show counter dhcp-server** command(cont.)

Parameter	Description
BOOTREQUEST in	The number of bootp messages received by the DHCP server from bootp clients.
BOOTREPLY out	The number of bootp messages sent by the DHCP server to bootp clients.
DHCPLEASEQUERY in	The number of Lease Query messages received by the DHCP server from DHCP relay agents.
DHCPLEASEUNKNOWN out	The number of Lease Unknown messages sent by the DHCP server to DHCP relay agents.
DHCPLEASEACTIVE out	The number of Lease Active messages sent by the DHCP server to DHCP relay agents.
DHCPLEASEUNASSIGNED out	The number of Lease Unassigned messages sent by the DHCP server to DHCP relay agents.

show ip dhcp pool

show dhcp lease

This command shows details about the leases that the DHCP client has acquired from a DHCP server for interfaces on the device.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show dhcp lease [<interface>]`

Parameter	Description
<interface>	Interface name to display DHCP lease details for.

Mode User Exec and Privileged Exec

Example To show the current lease expiry times for all interfaces, use the command:

```
awplus# show dhcp lease
```

To show the current lease for vlan1, use the command:

```
awplus# show dhcp lease vlan1
```

Output Figure 86-4: Example output from the **show dhcp lease** command

```
Interface vlan1
-----------------------------------------------------------------
IP Address:                     192.168.22.4
Expires:                        13 Mar 2007 20:10:19
Renew:                          13 Mar 2007 18:37:06

Related Commands ip address dhcp

show ip dhcp binding

This command shows the lease bindings that the DHCP server has allocated clients.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax

```
show ip dhcp binding [<ip-address>|<address-pool>]
```

Parameter	Description
<ip-address>	IPv4 address of a leased IP address, in dotted decimal notation. This displays the lease information for the specified IP address.
<address-pool>	Name of an address pool. This displays the lease information for all clients within the address pool.

Mode User Exec and Privileged Exec

Examples To display all leases for every client in all address pools, use the command:

```
awplus# show ip dhcp binding
```

To display the details for the leased IP address `172.16.2.16`, use the command:

```
awplus# show ip dhcp binding 172.16.2.16
```

To display the leases from the address pool `MyPool`, use the command:

```
awplus# show ip dhcp binding MyPool
```

Output Figure 86-5: Example output from the **show ip dhcp binding** command

```

show ip dhcp pool

This command displays the configuration details and system usage of the DHCP address pools configured on the device.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip dhcp pool [<address-pool>]`

Parameter	Description
<address-pool>	Name of a specific address pool. This displays the configuration of the specified address pool only.

Mode User Exec and Privileged Exec

Example

```
awplus# show ip dhcp pool
```

Output Figure 86-6: Example output from the **show ip dhcp pool** command

```
Pool p1 :
  network: 192.168.1.0/24
  address ranges:
    addr: 192.168.1.10 to 192.168.1.18
  static host addresses:
    addr: 192.168.1.12     MAC addr: 1111.2222.3333
  lease <days:hours:minutes:seconds> <1:0:0:0>
  subnet mask: 255.255.255.0 (pool's network mask)
  Probe:                          Default Values
    Status:       Enabled         [Enabled]
    Type:         ARP             [Ping]
    Packets:      2               [5]
    Timeout:      200 msecs       [200]
  Dynamic addresses:
    Total:        8
    Leased:       2
    Utilization:  25.0 %
  Static host addresses:
    Total:        1
    Leased:       1
```

Output Figure 86-7: Example output from the **show ip dhcp pool** command with IP address 192.168.1.12 assigned to a VLAN interface on the device:

```
Pool p1 :
  network: 192.168.1.0/24
  address ranges:
    addr: 192.168.1.10 to 192.168.1.18
             (interface addr 192.168.1.12 excluded)
             (static host addr 192.168.1.12 excluded)
  static host addresses:
    addr: 192.168.1.12     MAC addr: 1111.2222.3333
             (= interface addr, so excluded)
  lease <days:hours:minutes:seconds> <1:0:0:0>
  subnet mask: 255.255.255.0 (pool's network mask)
  Probe:                        Default Values
    Status:       Enabled       [Enabled]
    Type:         ARP           [Ping]
    Packets:      2             [5]
    Timeout:      200 msecs     [200]
  Dynamic addresses:
    Total:        8
    Leased:       2
    Utilization:  25.0 %
  Static host addresses:
    Total:        1
    Leased:       1
```

Table 86-4: Parameters in the output of the **show ip dhcp pool** command

Parameter	Description
`Pool`	Name of the pool.
`network`	Subnet and mask length of the pool.
`address ranges`	Individual IP addresses and address ranges configured for the pool. The DHCP server can offer clients an IP address from within the specified ranges only. Any of these addresses that match an interface address on the device, or a static host address configured in the pool, will be automatically excluded from the range, and a message to this effect will appear beneath the range entry.
`static host addresses`	The static host addresses configured on the pool. Each IP address is permanently assigned to the client with the matching MAC address. Any of these addresses that match an interface address on the device will be automatically excluded, and a message to this effect will appear beneath the static host entry.
`lease <days:hours:minutes>`	The lease duration for address allocated by this pool.
`domain`	The domain name sent by the pool to clients. This is the domain name that the client should use when resolving host names using DNS.
`subnet mask`	The subnet mask sent by the pool to clients.
`Probe - Status`	Whether lease probing is enabled or disabled.
`Probe - Type`	The lease probe type configured. Either ping or ARP.

Table 86-4: Parameters in the output of the **show ip dhcp pool** command(cont.)

Parameter	Description
`Probe - Packets`	The number of packets sent for each lease probe in the range 0 to 10.
`Probe - Timeout`	The timeout value in milliseconds to wait for a response after each probe packet is sent. In the range 50 to 5000.
`dns servers`	The DNS server addresses sent to by the pool to clients.
`default-router(s)`	The default router addresses sent by the pool to clients.
`user-defined options`	The list of user-defined options sent by the pool to clients.
`Dynamic addresses - Total`	The total number of IP addresses that have been configured in the pool for dynamic allocation to DHCP clients.
`Dynamic addresses - Leased`	The number of IP addresses in the pool that have been dynamically allocated (leased) to DHCP clients.
`Dynamic addresses - Utilization`	The percentage of IP addresses in the pool that are currently dynamically allocated to clients.
`Static host addresses - Total`	The number of static IP addresses configured in the pool for specific DHCP client hosts.
`Static host addresses - Leased`	The number of static IP addresses assigned to specific DHCP client hosts.

show ip dhcp-relay

This command shows the configuration of the DHCP relay agent on each interface.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip dhcp-relay [interface <interface-name>]`

Parameter	Description
<interface-name>	Name of a specific interface. This displays the DHCP configuration for the specified interface only.

Mode User Exec and Privileged Exec

Example To display the DHCP relay agent's configuration on the interface `vlan100`, use the command:

```
awplus# show ip dhcp-relay interface vlan100
```

Output Figure 86-8: Example output from the **show ip dhcp-relay** command

```
DHCP Relay Service is enabled

vlan100 is up, line protocol is up
Maximum hop count is 10
Insertion of Relay Agent Option is disabled
Checking of Relay Agent Option is disabled
The Remote Id string for Relay Agent Option is 0000.cd28.074c
Relay information policy is to append new relay agent
information
List of servers :   192.168.1.200
```

Related Commands
ip dhcp-relay agent-option
ip dhcp-relay agent-option checking
ip dhcp-relay information policy
ip dhcp-relay maxhops

show ip dhcp server statistics

This command shows statistics related to the DHCP server.

You can display the server counters using the show counter dhcp-server command as well as with this command.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip dhcp server statistics`

Mode User Exec and Privileged Exec

Example To display the server statistics, use the command:

```
awplus# show ip dhcp server statistics
```

Output Figure 86-9: Example output from the **show counter dhcp server statistics** command

```
DHCP server counters
DHCPDISCOVER in       ......... 20
DHCPREQUEST in        ......... 12
DHCPDECLINE in        ......... 1
DHCPRELEASE in        ......... 0
DHCPINFORM in         ......... 0
DHCPOFFER out         ......... 8
DHCPACK out           ......... 4
DHCPNAK out           ......... 0
BOOTREQUEST in        ......... 0
BOOTREPLY out         ......... 0
DHCPLEASEQUERY in       ....... 0
DHCPLEASEUNKNOWN out    ....... 0
DHCPLEASEACTIVE out     ....... 0
DHCPLEASEUNASSIGNED out ....... 0
```

Figure 86-10: Parameters in the output of the **show counter dhcp server statistics** command

Parameter	Description
DHCPDISCOVER in	The number of Discover messages received by the DHCP server.
DHCPREQUEST in	The number of Request messages received by the DHCP server.
DHCPDECLINE in	The number of Decline messages received by the DHCP server.
DHCPRELEASE in	The number of Release messages received by the DHCP server.
DHCPINFORM in	The number of Inform messages received by the DHCP server.
DHCPOFFER out	The number of Offer messages sent by the DHCP server.
DHCPACK out	The number of Acknowledgement messages sent by the DHCP server.

Figure 86-10: Parameters in the output of the **show counter dhcp server statistics** command(cont.)

`DHCPNAK out`	The number of Negative Acknowledgement messages sent by the DHCP server. The server sends these after receiving a request that it cannot fulfil because either there are no available IP addresses in the related address pool, or the request has come from a client that doesn't fit the network setting for an address pool.
`BOOTREQUEST in`	The number of bootp messages received by the DHCP server from bootp clients.
`BOOTREPLY out`	The number of bootp messages sent by the DHCP server to bootp clients.
`DHCPLEASEQUERY in`	The number of Lease Query messages received by the DHCP server from DHCP relay agents.
`DHCPLEASEUNKNOWN out`	The number of Lease Unknown messages sent by the DHCP server to DHCP relay agents.
`DHCPLEASEACTIVE out`	The number of Lease Active messages sent by the DHCP server to DHCP relay agents.
`DHCPLEASEUNASSIGNED out`	The number of Lease Unassigned messages sent by the DHCP server to DHCP relay agents.

Related Commands

show counter dhcp-server
service dhcp-server
show ip dhcp binding
show ip dhcp pool

show ip dhcp server summary

This command shows the current configuration of the DHCP server. This includes:

- whether the DHCP server is enabled
- whether the DHCP server is configured to ignore BOOTP requests
- whether the DHCP server is configured to support DHCP lease queries
- the details of any user-defined options
- a list of the names of all DHCP address pools currently configured

This show command does not include any configuration details of the address pools. You can display these using the show ip dhcp pool command.

For information on output options, see "Controlling "show" Command Output" on page 1.41.

Syntax `show ip dhcp server summary`

Mode User Exec and Privileged Exec

Example To display the current configuration of the DHCP server, use the command:

```
awplus# show ip dhcp server summary
```

Output Figure 86-11: Example output from the **show ip dhcp server summary** command

```
DHCP Server service is disabled
BOOTP ignore is disabled
DHCP leasequery support is disabled
Pool list: p2
```

Related Commands
ip dhcp leasequery enable
ip dhcp pool
service dhcp-server

subnet-mask

This command sets the subnet mask option for a DHCP address pool you are configuring. Use this command to specify the client's subnet mask as defined in RFC 950. This sets the subnet details using the pre-defined option 1. Note that if you create a user-defined option 1 using the option command, then you will override any settings created with this command. If you do not specify a subnet mask using this command, then the pool's network mask (specified using the next-server command) is applied.

The no variant of this command removes a subnet mask option from a DHCP pool. The pool reverts to using the pool's network mask.

Syntax

```
subnet-mask <mask>
no subnet-mask
```

Parameter	Description
<mask>	Valid IPv4 subnet mask, in dotted decimal notation.

Mode DHCP Configuration

Examples To set the subnet mask option to `255.255.255.0` for DHCP pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# subnet-mask 255.255.255.0
```

To remove the subnet mask option from DHCP pool `P2`, use the commands:

```
awplus# configure terminal
awplus(config)# ip dhcp pool P2
awplus(dhcp-config)# no subnet-mask
```

Introduction

The Simple Network Management Protocol (SNMP) is the network management protocol of choice for the Internet and IP-based internetworks.

This chapter describes the main features of SNMP Version 1 (SNMPv1), SNMP Version 2c (SNMPv2c) and Version 3 (SNMPv3). It also describes support for SNMP on the switch, and how to configure the switch's SNMP agent.

Unless a particular version of SNMP is named, "SNMP" in this chapter refers to versions SNMPv1, SNMPv2c and SNMPv3.

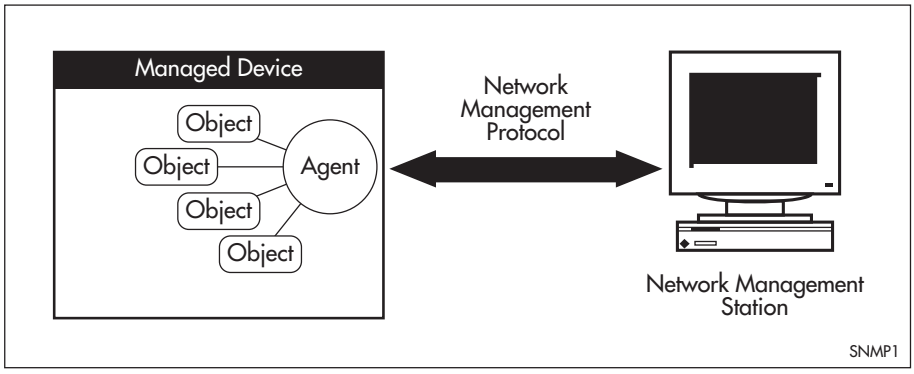
See also Chapter 88, SNMP Commands and Chapter 89, SNMP MIBs.

Network Management Framework

A network management system has the following components:

- One or more managed devices, each containing an agent that provides the management functions. A managed device may be any computing device with a network capability, for example, a host system, workstation, terminal server, printer, router, switch, bridge, hub or repeater.
- One or more Network Management Stations (NMS). An NMS is a host system running a network management protocol and network management applications, enabling the user to manage the network.
- A network management protocol used by the NMS and agents to exchange information.

Figure 87-1: Components of a network management system



The Internet-standard Network Management Framework is the framework used for network management in the Internet. The framework was originally defined by the following documents:

- RFC 1155, *Structure and identification of management information for TCP/IP based internets* (referred to as the SMI), details the mechanisms used to describe and name the objects to be managed.
- RFC 1213, *Management Information Base for network management of TCP/ IP-based internets: MIB-II* (referred to as MIB-II), defines the core set of managed objects for the Internet suite of protocols. The set of managed objects can be extended by adding other MIBs specific to particular protocols, interfaces or network devices.
- RFC 1157, *A Simple Network Management Protocol (SNMP)*, is the protocol used for communication between management stations and managed devices.

Subsequent documents that have defined SNMPv2c are:

- RFC 1901, *Introduction to Community-based SNMPv2*
- RFC 1902, *Structure of Management Information for Version 2 of the Simple Network Management Protocol (SNMPv2)*
- RFC 1903, *Textual Conventions for Version 2 of the Simple Network Management Protocol (SNMPv2)*
- RFC 1904, *Conformance Statements for Version 2 of the Simple Network Management Protocol*
- RFC 1905, *Protocol Operations for Version 2 of the Simple Network Management Protocol (SNMPv2)*
- RFC 1906, *Transport Mappings for Version 2 of the Simple Network Management Protocol (SNMPv2)*
- RFC 1907, *Management Information Base for Version 2 of the Simple Network Management Protocol (SNMPv2)*
- RFC 2576, *Coexistence between Version 1, Version 2, and Version 3 of the Internet-standard Network Management Framework*
- RFC 2578, *Structure of Management Information Version 2 (SMIv2)*
- RFC 2579, *Textual Conventions for SMIv2*
- RFC 2580, *Conformance Statements for SMIv2*

Subsequent documents that have defined SNMPv3 are:

- RFC 3410, *Introduction and Applicability Statements for Internet Standard Management Framework*
- RFC 3411, *An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks*
- RFC 3412, *Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)*
- RFC 3413, *Simple Network Management Protocol (SNMP) Applications*
- RFC 3414, *User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)*
- RFC 3415, *View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)*
- RFC 3416, *Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)*
- RFC 3417, *Transport Mappings for the Simple Network Management Protocol (SNMP)*
- RFC 3418, *Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)*

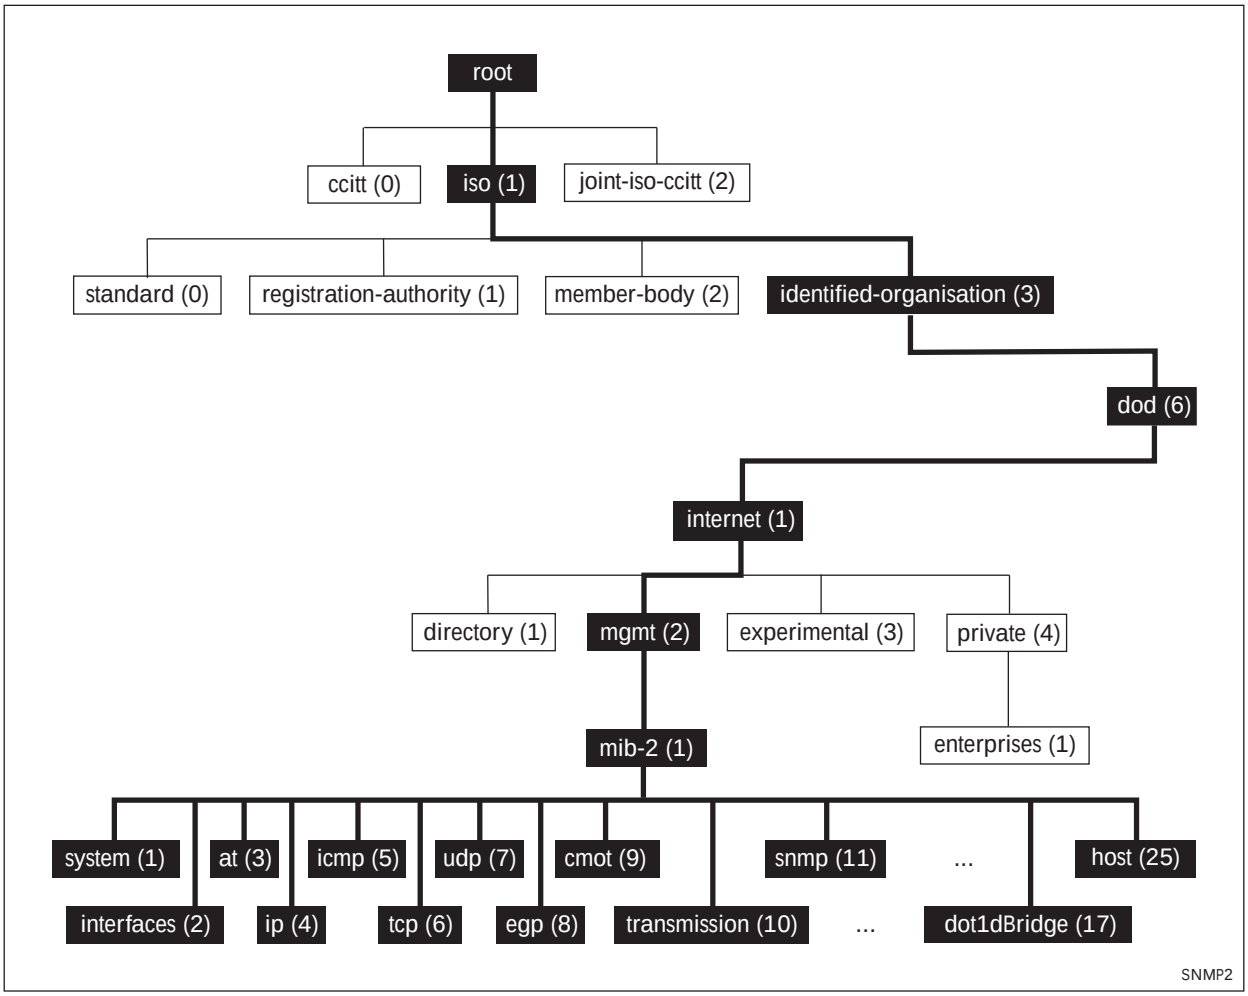
Structure of Management Information

The structure of management information (SMI) defines the schema for a collection of managed objects residing in a virtual store called the management information base (MIB). The information in a MIB includes administrative and operational configuration information, as well as counters of system events and activities.

The MIB is organized into a tree-like hierarchy in which nodes are each assigned an identifier consisting of a non-negative integer and an optional brief textual description.

Each managed object is represented by a leaf node and is defined by its name, syntax, access mode, status and description. It can also be specifically identified by its unique position within the tree. This position is expressed as a series of dot-delimited sub-identifiers that start at the root node and end in the sub-identifier at the particular object's leaf node. For example, in Figure 87-2 the object named interfaces would be uniquely identified by the string of individual sub-identifiers, 1.3.6.1.2.1.2.

Figure 87-2: Top levels of the Internet-standard Management Information Base (MIB)



Objects defined in the Internet-standard MIB (MIB-II) reside in the mib(1) sub-tree.

Names

Names are used to identify managed objects, and are hierarchical in nature. An object identifier is a globally unique, authoritatively assigned sequence of non-negative integers which traverse the MIB tree from the root to the node containing the object.

Object identifiers may be represented in one of the following forms:

- Dotted notation lists the integer values found by traversing the tree from the root to the node in question, separated by dots. For example, the following identifies the MIB-II sub-tree:

  ```
  1.3.6.1.2.1
  ```

  The following identifies the sysDescr object in the system group of MIB-II:

  ```
  1.3.6.1.2.1.1.1
  ```

- Textual notation lists the textual descriptions found by traversing the tree from the root to the node in question, separated by spaces and enclosed in braces. For following example identifies the internet sub-tree:

  ```
  { iso org dod 1}
  ```

  The name may be abbreviated to a relative form. The following example identifies the first (directory) node of the internet sub-tree:

  ```
  { internet 1}
  ```

- Combined notation lists both the integer values and textual descriptions found by traversing the tree from the root to the node in question. The integer value is placed in parentheses after the textual description. The labels are separated by spaces and enclosed in braces. For example, the following identifies the first (directory) node in the internet sub-tree:

  ```
  {iso(1) org(3) dod(6) internet(1) 1}
  ```

  The name may be abbreviated to the following:

  ```
  directory(1)
  ```

Since there is no effective limit to the magnitude of non-negative integers, and no effective limit to the depth of the tree, the MIB provides an unlimited name space.

An object is also usually assigned an object descriptor. The object descriptor is a unique, mnemonic, printable string intended for humans to use when discussing the MIB.

Instances

Objects are just templates for data types. An actual value that can be manipulated by an NMS is an instance of an object. An instance is named by appending an instance identifier to the end of the object's object identifier. The instance identifier depends on the object's data type:

- If the object is not a column in a table, the instance identifier is 0 (zero). For example, the instance of the sysDescr object is:

  ```
  sysDescr.0
  or 1.3.6.1.2.1.1.1.0
  ```

- If the object is a column in a table, the method used to assign an instance identifier varies. Typically, the value of the index column or columns is used.

The object ifTable in MIB-II contains information about interfaces and is indexed by the interface number, ifIndex. The instance of the ifDescr object for the first interface is:

```
ifDescr.1
or 1.3.6.1.2.1.2.2.1.2.1
```

If the index column is an IP address, the entire IP address is used as the instance identifier. The object ipRouteTable in MIB-II contains information about IP routes and is indexed by the destination address, ipRouteDest. The instance of the ipRouteNextHop object for the route 131.203.9.0 is:

```
ipRouteNextHop.131.203.9.0
or 1.3.6.1.2.1.4.21.1.7.131.203.9.0
```

If the table has more than one index, the values of all the index columns are combined to form the instance identifier. The object tcpConnTable in MIB-II contains information about existing TCP connections and is indexed by the local IP address (tcpConnLocalAddress), the local port number (tcpConnLocalPort), the remote IP address (tcpConnRemAddress) and the remote port number (tcpConnRemPort) of the TCP connection. The instance of the tcpConnState object for the connection between 131.203.8.36,23 and 131.203.9.197,1066 is:

tcpConnState.131.203.8.36.23.131.203.9.197.1066
or 1.3.6.1.2.1.6.13.1.1.131.203.8.36.23.131.203.9.197.1066

Syntax

The syntax of an object describes the abstract data structure corresponding to that object type. For example, INTEGER or OCTET STRING.

Access

The access mode of an object describes the level of access for the object.

Access modes for MIB objects:

Access	Description
Read-only	The object's value can be read but not set.
Read-write	The object's value can be read and set.
Write-only	The object's value can be set but not read.
Not-accessible	The object's value cannot be read or set.

Status

The status of an object describes the implementation requirements for the object.

Status values for MIB objects:

Status	Description
Mandatory	Managed devices must implement the object.
Optional	Managed devices may implement the object.
Obsolete	Managed devices need no longer implement the object.
Deprecated	Managed devices should implement the object. However, the object may be deleted from the next version of the MIB. A new object with equal or superior functionality is defined.

Description

The definition of an object may include an optional textual description of the meaning and use of the object. This description is often essential for successful understanding of the object.

The SNMP Protocol

The SNMP protocol provides a mechanism for management entities, or stations, to extract information from the Management Information Base (MIB) of a managed device.

The normal method of accessing information in a MIB is to use a Network Management Station (NMS), typically a PC or workstation, to send commands to the managed device (in this case the switch) using the SNMP protocol.

SNMP can use a number of different protocols as its underlying transport mechanism, but the most common transport protocol, and the only one supported by the switch, is UDP. Therefore the IP module must be enabled and properly configured in order to use SNMP. SNMP trap messages are sent to UDP port 162; all other SNMP messages are sent to UDP port 161. The switch's SNMP agent accepts SNMP messages up to the maximum UDP length the switch can receive.

Other transport mappings have been defined (e.g. OSI [RFC 1418], AppleTalk [RFC 1419] and IPX [RFC 1420]), but the standard transport mapping for the Internet (and the one the switch uses) is UDP. The IP module must be enabled and configured correctly. See Chapter 25, IP Addressing and Protocol Commands for detailed descriptions of the commands required to enable and configure IP.

SNMP Versions

The switch supports SNMP version 1 (SNMPv1), SNMP version 2c (SNMPv2c) and SNMP Version 3 (SNMPv3). The three versions operate similarly.

SNMPv2c updated the original protocol, and offered the following main enhancements:

- a new format for trap messages.
- the get-bulk-request PDU allows for the retrieval of large amounts of data, including tables, with one message.
- more error codes mean that error responses to set messages have more detail than is possible with SNMPv1.
- three new exceptions to errors can be returned for get, get-next and get-bulk-request messages. These are: noSuchObject, noSuchInstance, and endOfMibView.

SNMPv3 provides significant enhancements to address the security weaknesses existing in the earlier versions. This is achieved by implementing two new major features:

- Authentication - by using password hashing and time stamping.
- Privacy - by using message encryption.

Support for multiple versions of SNMP is achieved by responding to each SNMP request with a response of the same version. For example, if an SNMPv1 request is sent to the switch, an SNMPv1 response is returned. If an SNMPv2c request is sent, an SNMPv2c response is returned. Therefore, authentication and encryption functions are not invoked when messages are detected as having either an SNMPv1 or SNMPv2c protocol format.

SNMP Messages

The SNMP protocol is termed simple because it has only six operations, or messages—get, get-next, get-response, set, and trap, and SNMPv2c also has the get-bulk-request message. The replies from the managed device are processed by the NMS and generally used to provide a graphical representation of the state of the network. The two major SNMP operations available to a management station for interacting with a client are the get and set operations. The SNMP set operator can lead to security breaches, since SNMP is not inherently very secure. When forced to operate in either SNMPv1 or v2 mode, when operating with older management stations for example, care must be taken in the choice and safe-guarding of community names, which are effectively passwords for SNMP.

Polling versus Event Notification

SNMP employs a polling paradigm. A Network Management Station (NMS) polls the managed device for information as and when it is required, by sending get-request, get-next-request, and/or get-bulk-request PDUs to the managed device. The managed device responds by returning the requested information in a get-response PDU. The NMS may manipulate objects in the managed device by sending a set-request PDU to the managed device.

The only time that a managed device initiates an exchange of information is in the special case of a trap PDU. A managed device may generate a limited set of traps to notify the NMS of critical events that may affect the ability of the NMS to communicate with the managed device or other managed devices on the network, and therefore to “manage” the network. Such events include the restarting or re-initialization of a device, a change in the status of a network link (up or down), or an authentication failure.

Message Format for SNMPv1 and SNMPv2c

Table 87-1: Fields in an SNMP message

Field	Function
Version	The version of the SNMP protocol. The value is version-1 (0) for the SNMP protocol as defined in RFC 1157, or version-2c (1) for the SNMP protocol as defined in RFC 1902.
Community	The name of an SNMP community, for authentication purposes
SNMP PDU	An SNMP Protocol Data Unit (PDU).

Table 87-2: SNMP PDUs

PDU	Function
get-request	Sent by an NMS to an agent, to retrieve the value of an object.
get-next-request	Sent by an NMS to an agent, to retrieve the value of the next object in the sub-tree. A sub-tree is traversed by issuing a get-request PDU followed by successive get-next-request PDUs.
get-bulk-request	Sent by an NMS to an agent to request a large amount of data with a single message. This is for SNMPv2c messages.
set-request	Sent by an NMS to an agent, to manipulate the value of an object. SNMP PDU Version Community
get-response	Sent by an agent to an NMS in response to a get-request, get-next-request, get-bulk-response, or set-request PDU.
trap	Sent by an agent to an NMS to notify the NMS of a extraordinary event.
report	Although not explicitly defined in the RFCs, reports are used for specific purposes such as EngineID discovery and time synchronization.

Table 87-3: Generic SNMP traps

Value	Meaning
coldStart	The agent is re-initializing itself. Objects may be altered.
warmStart	The agent is re-initializing itself. Objects are not altered.
linkDown	An interface has changed state from up to down.
linkUp	An interface has changed state from down to up.
authenticationFailure	An SNMP message has been received with an invalid community name.
egpNeighborLoss	An EGP peer has transitioned to down state.

SNMP Communities (Version v1 and v2c)

A community is a relationship between an NMS and an agent. The community name is used like a password for a trivial authentication scheme. Both SNMPv1 and SNMPv2c provide security based on the community name only. The concept of communities does not exist for SNMPv3, which instead provides for a far more secure communications method using entities, users, and groups.

Caution

We strongly recommend removing community membership from all SNMPv3 configured devices to prevent access to them via SNMPv1 and SNMv2c, which could bypass the additional SNMPv3 security features.

SNMPv3 Entities

Entities comprise one of the basic components of the SNMPv3 enhanced architecture. They define the functionality and internal structure of the SNMP managers and agents. An in-depth description of entities can be found in RFC 3411, on which the following text is based. SNMPv3 defines two entity types, a manager and an agent. Both entity types contain two basic components: an SNMP engine and a set of applications.

SNMP Engine

The engine provides the basic services to support the agents component applications, in this respect it performs much of the functionality expected of the ISO Session and Presentation layers. These functions include message transmission and reception, authentication and encryption, and access control to its managed objects database (MIB). The SNMP engine comprises the following components:

- Dispatcher
- Message processing Subsystem
- Security Subsystem
- Access Control Subsystem

The only security subsystem presently supported is the user based security model (USM).

Each SNMP engine is identified by an snmpEngineID that must be unique within the management system. A one to one association exists between an engine and the entity that contains it.

Entity Applications

The following applications are defined within the agent applications:

- Command Generator
- Notification Receiver
- Proxy Forwarder
- Command Responder
- Notification Originator
- Other

SNMPv3 Message Protocol Format

Table 87-4: SNMPv3 PDUs

Value	Meaning
msgVersion	Identifies the message format to be SNMPv3.
msgID	An identifier used between SNMP entities to coordinate message requests and responses. Note that a message response takes the msgID value of the initiating message.
msgMaxSize	Conveys the maximum message size (in octets) an integer between 484 and 2^{31}-1, supported by the sender of the message. Specified as msgFlags. A single octet whose last three bits indicate the operational mode for privacy, authentication, and report.
msgSecurityModel	An identifier used to indicate the security mode (i.e. SNMPv1, SNMPv2c or SNMPv3 to be used when processing the message. Note that although only the SNMPv3 identifier is accepted by the switch, these earlier version message formats are detected by the msgVersion field and processed appropriately.
msgAuthoritativeEngineID	The ID of the authoritative engine that relates to a particular message, i.e. the source engine ID for Traps, Responses and Reports, and the destination engine for Gets, GetNexts, Sets, and Informs.
msgAuthoritativeEngineBoots	A value that represents the number of times the authoritative engine has rebooted since its installation. Its value has the range 1 to 2^{31}-1.
msgAuthoritativeEngineTime	The number of seconds since the authoritative engine snmpEngineBoots counter was last incremented.
msgUserName	The name of the user (principal) on whose behalf the message is being exchanged.
msgAuthenticationParameters	If the message has been authenticated, this field contains a serialized OCTET STRING representing the first 12 octets of the HMAC-MD5-96 output done over the whole message.
msgPrivacyParameters	For encrypted data, this field contains the "salt" used to create the DES encryption Initialization Vector (IV).
ContextEngineID	Within a particular administrative domain, this field uniquely identifies an SNMP entity that may realize an instance of a context with a particular contextName
ContextName	A unique name given to a context within a particular SNMP entity.

SNMPv1 and SNMPv2c

Although software levels 2.6.3 and higher support the specific facilities of SNMP v1 and v2, their documentation is available to provide backward compatibility with older network management systems. The far superior security features offered by implementing SNMPv3 should be used wherever possible.

The switch's implementation of SNMPv1 is based on RFC 1157, *A Simple Network Management Protocol (SNMP)*, and RFC 1812, *Requirements for IP Version 4 Routers*.

When the SNMP agent is disabled, the agent does not respond to SNMP request messages. The agent is disabled by default. The current state and configuration of the SNMP agent can be displayed.

SNMP MIB Views for SNMPv1 and SNMPv2c

An SNMP MIB view is a arbitrary subset of objects in the MIB. Objects in the view may be from any part of the object name space, and not necessarily the same sub-tree. An SNMP community profile is the pairing of an SNMP access mode (read-only or read-write) with the access mode defined by the MIB for each object in the view. For each object in the view, the community profile defines the operations that can be performed on the object.

Pairing an SNMP community with an SNMP community profile determines the level of access that the agent affords to an NMS that is a member of the specified community. When an agent receives an SNMP message, it checks the community name encoded in the message. If the agent knows the community name, the message is deemed to be authentic and the sending SNMP entity is accepted as a member of the community. The community profile associated with the community name then determines the sender's view of the MIB and the operations that can be performed on objects in the view.

SNMP Communities

SNMP communities were introduced into SNMPv1 and retained in version 2c. Although the switch's software still supports communities, this is to provide backward compatibility with legacy management systems. Communities should not be used where a secure network is required. Instead, use the secure network features offered by SNMPv3.

An SNMP community is a pairing of an SNMP agent with a set of SNMP application entities. Communities are the main configuration item in the switch's implementation of SNMPv1 and v2, and are defined in terms of a list of IP addresses which define the SNMP application entities (trap hosts and management stations) in the community.

Important community names act as passwords and provide minimal authentication. Any SNMP application entity that knows a community name can read the value of any instance of any object in the MIB implemented in the switch. Any SNMP application entity that knows the name of a community with write access can change the value of any instance of any object in the MIB implemented in the switch, possibly affecting the operation of the switch. For this reason, take care with the security of community names.

When a trap is generated by the SNMP agent it is forwarded to all trap hosts in all communities. The community name and manager addresses are used to provide trivial authentication. An incoming SNMP message is deemed authentic if it contains a valid community name and originated from an IP address defined as a management station for that community.

When a community is disabled, the SNMP agent behaves as if the community does not exist and generates authentication failure traps for messages directed to the disabled community.

The SNMP agent does not support a default community called “public” with read-only access, traps disabled and open access as mandated in RFC 1812, as this is a security hole open for users who wish to use the switch with minimal modification to the default configuration. The default configuration of the switch has no defined communities. Communities must be explicitly created.

SNMP authentication (for SNMPv1 and v2) is a mechanism whereby an SNMP message is declared to be authentic, that is from an SNMP application entity actually in the community to which the message purports to belong. The mechanism may be trivial or secure. The only form of SNMP authentication implemented by the switch’s SNMP agent is trivial authentication. The authentication failure trap may be generated as a result of the failure to authentication an SNMP message.

Switch interfaces can be enabled or disabled via SNMP by setting the ifAdminStatus object in the ifTable of MIB-II MIB to ‘Up(1)’ or ‘Down(2)’ for the corresponding ifIndex. If it is not possible to change the status of a particular interface the switch returns an SNMP error message.

The switch’s implementation of the ifOperStatus object in the ifTable of MIB-II MIB supports two additional values—”Unknown(4)” and “Dormant(5)” (e.g. an inactive dial-on-demand interface).

Caution

An unauthorized person with knowledge of the appropriate SNMP community name could bring an interface up or down. Community names act as passwords for the SNMP protocol. When creating an SNMP community with write access, take care to select a secure community name and to ensure that only authorized personnel know it.

An SNMP MIB view is a subset of objects in the MIB that pertain to a particular network element. For example, the MIB view of a hub would be the objects relevant to management of the hub, and would not include IP routing table objects, for example. The switch’s SNMP agent does not allow the construction of MIB views. The switch supports all relevant objects from all MIBs that it implements.

Note that the switch’s standard set and show commands can also be used to access objects in the MIBs supported by the switch.

Defining Management Stations within Communities

You can add management stations to a community either individually, by entering just its IP address, or you can enter a range of management stations by entering an IP address that ends with a ‘/’ character followed by a number between 1 and 32. The number that follows the ‘/’ character operates as an address mask to define a range of addresses for the management stations. The following example shows how to allocate a band of three binary addresses to a portion of the subnet 146.15.1.X

Example

In this example we make provision for up to 8 possible management stations within a community called “admin”.

Step 1:

Decide on the number of management stations that you want to assign to a particular subnet, then decide how many binary digits are required to define this number of addresses. In this case we need up to 8 management stations, so we will assign 3 binary digits (3 binary digits can provide 8 different values). To assign the last 3 binary digits for management stations, we assign a prefix that is a count of all binary digits in the address minus those to be assigned as management stations. In this case the prefix is 29; this being the number of binary digits in an IP address (32) minus the number of digits assigned to the management stations (3).

Step 2:

The method used in this step depends on whether or not the community already exists.

- If the community called “admin” does not exist, create a new community called “admin” and allocate a three binary digit block of addresses to the address subnet 146.15.1.X.
- If the community called “admin” already exists, allocate a three binary digit block of addresses to an existing community called “admin” with the address subnet 146.15.1.X.

For security reasons, the common management prefix should be larger than the IP subnet. This prevents stations on one subnet from being considered valid management stations on a different subnet.

Configuration Example (SNMPv1 and v2)

This example shows how to configure the switch’s SNMP agent. Two network management stations have been set up on a large network. The central NMS (IP address 192.168.11.5) monitors devices on the network and uses SNMP set messages to manage devices on the network. Trap messages are sent to this management station. The regional network management station (IP addresses 192.168.16.1) is used just to monitor devices on the network by using SNMP get messages. Link traps are enabled for all interfaces on this particular switch.

IP and VLANs must be correctly configured in order to access the SNMP agent in the switch. This is because the IP module handles both the TCP transport functions, and the UDP functions that enable datagrams to transport SNMP messages. See Chapter 25, IP Addressing and Protocol Commands for commands that enable and configure IP.

To configure SNMP

Step 1: Enable the SNMP agent.

Enable the SNMP agent and enable the generation of authenticate failure traps to monitor unauthorized SNMP access. SNMP is enabled by default in AlliedWare Plus.

```
awplus(config)# snmp-server enable trap auth
```

Step 2: Create a community with write access for the central NMS.

Create a write access community called “example1rw” for use by the central network management station at 192.168.11.5 Use an ACL to give the central NMS SNMP access to the switch using that community name.

```
awplus(config)# access-list 66 permit 192.168.11.5
awplus(config)# snmp-server community example1rw rw 66
```

Care must be taken with the security of community names. Do not use the names “private” or “public” in your network because they are too obvious. Community names act as passwords and provide only trivial authentication. Any SNMP application entity that knows a community name can read the value of any instance of any object in the MIB implemented in the switch. Any SNMP application entity that knows the name of a community with write access can change the value of any instance of any object in the MIB implemented in the switch, possibly affecting the operation of the switch.

SNMP V1 or V2c provide very minimal security. If security is a concern, you should use SNMPv3.

Step 3: Create a community with read-only access for the regional NMS.

Create a read-only access community called “example2ro” for use by the regional network management station at 192.168.16.1. Use an ACL to give the regional NMS SNMP access to the switch using that community name.

```
awplus(config)# access-list 67 permit 192.168.16.1
awplus(config)# snmp-server community example2ro ro 67
```

Step 4: Enable link traps.

Enable link traps for the desired interfaces. In this example, the NSMs are in VLAN 2 and VLAN 3 and other ports are in VLAN 1 for simplicity.

```
awplus(config)# interface vlan1-3
awplus(config-if)# snmp trap link-status
```

Note that link traps on VLANs are sent when the last port in the VLAN goes down. You will only see a trap for a VLAN if the trap host is in a different VLAN.

You can also enable link traps on channel groups and switch ports. For example, to enable traps on a range of switch ports:

```
awplus(config)# int port1.0.5-1.0.7
awplus(config-if)# snmp trap link-status
```

You can also enable link traps on channel groups and switch ports. For example, to enable traps on a range of switch ports:

Step 5: Configure trap hosts.

Specify the IP address or addresses that the traps will get sent to. In this example, traps will be sent to both NMSes.

```
awplus(config)# snmp-server host 192.168.11.5 version 2c
                example1rw
awplus(config)# snmp-server host 192.168.16.1 version 2c
                example2ro
```

Step 6: Check the configuration.

Check that the current configuration of the SNMP communities matches the desired configuration:

```
awplus# show snmp-server
awplus# show snmp-server community
awplus# show run snmp
```

This is the output of the show snmp-server community command for this example:

```
SNMP community information:
  Community Name ........... example1rw
    Access ................. Read-write
    View ................... none
  Community Name ........... example2ro
    Access ................. Read-only
    View ................... none
```

This is the output of the show run snmp command for this example:

```
no snmp-server ipv6
snmp-server enable trap auth
snmp-server community example1rw rw 66
snmp-server community example2ro 67
snmp-server host 192.168.1.2 version 2c example1rw
snmp-server host 192.168.2.2 version 2c example2ro
!
```

Check that the interface link up/down traps have been correctly configured:

```
awplus# show interface vlan1-3
```

This is the output of the show interface command for this example:

```
Interface vlan1
  Scope: both
  Link is UP, administrative state is UP
  Hardware is VLAN, address is 0009.41fd.c029
  index 201 metric 1 mtu 1500
  arp ageing timeout 300
  <UP,BROADCAST,RUNNING,MULTICAST>
  VRF Binding: Not bound
  SNMP link-status traps: Sending (suppressed after 20 traps in 60 sec)
  Bandwidth 1g
    input packets 4061, bytes 277043, dropped 0, multicast   packets 3690
    output packets 190, bytes 18123, multicast packets 0 broadcast packets 0
Interface vlan2
  Scope: both
  Link is DOWN, administrative state is UP
  Hardware is VLAN, address is 0009.41fd.c029
  IPv4 address 192.168.11.50/24 broadcast 192.168.11.255
  index 202 metric 1 mtu 1500
  arp ageing timeout 300
  <UP,BROADCAST,MULTICAST>
  VRF Binding: Not bound
  SNMP link-status traps: Sending (suppressed after 20 traps in 60 sec)
  Bandwidth 1g
    input packets 568, bytes 42309, dropped 0, multicast packets 0
    output packets 183, bytes 18078, multicast packets 0 broadcast packets 0
Interface vlan3
  Scope: both
  Link is DOWN, administrative state is UP
  Hardware is VLAN, address is 0009.41fd.c029
  IPv4 address 192.168.16.50/24 broadcast 192.168.16.255
  index 203 metric 1 mtu 1500
  arp ageing timeout 300
  <UP,BROADCAST,MULTICAST>
  VRF Binding: Not bound
  SNMP link-status traps: Sending (suppressed after 20 traps in 60 sec)
    input packets 0, bytes 0, dropped 0, multicast packets 0
    output packets 0, bytes 0, multicast packets 0 broadcast packets 0
```

SNMPv3

SNMPv3 is the third version of the Simple Network Management Protocol. The architecture comprises the following:

- entities that may be either managers, agents, or both
- a management information base (MIB)
- a transport protocol

At least one manager node runs the SNMP management software in every configuration. Managed devices such as routers, servers, and workstations are equipped with an agent software module. The agent provides access to local objects in the MIB that reflect activity and resources at the node. The agent also responds to manager commands to retrieve values from, and set values in the MIB.

SNMP MIB Views for SNMPv3

An SNMP MIB view is a arbitrary subset of objects in the MIB. Objects in the view may be from any part of the object name space, and not necessarily the same sub-tree.

SNMP Groups

Groups were introduced as part of SNMPv3. They are the means by which users are assigned their views and access control policy. Once a group has been created, users can be added to them. In practice a number of groups would be created, each with varying views and access security requirements. Users would then be added to their most appropriate groups. Each Group name and Security Level pair must be unique within a switch.

SNMP Users

Users were introduced as part of SNMPv3. From a system perspective a user is represented as an entity stored in a table that defines the access and authentication criteria to be applied to access or modify the SNMP MIB data.

SNMP Target Addresses

Target addresses were introduced as part of SNMPv3. They specify the destination and user that receives outgoing notifications such as trap messages. SNMP target address names must be unique within the managed device.

SNMP Target Params

Target params were introduced as part of SNMPv3. They specify an entry in the snmpTargetParamsTable. SNMP target params names must be unique within the managed device.

Configuration Example (SNMPv3)

This example shows how to configure the switch's SNMP agent. Two network management stations have been set up on a large network. The central NMS (IP address 192.168.11.5) monitors devices on the network and uses SNMP set messages to manage devices on the network. Trap messages are sent to this management station.

The IP module must be enabled and correctly configured in order to access the SNMP agent in the switch, since the IP module handles the UDP datagrams used to transport SNMP messages.

To configure SNMP

Step 1: Enable the SNMP agent.

Enable the SNMP agent and enable the generation of authenticate failure traps to monitor unauthorized SNMP access. SNMP is enabled by default in AlliedWare Plus.

Step 2: Add SNMP views.

You can specify views using their OID or the predefined MIB name.

```
awplus(config)# snmp-server view atmib 1.3.6.1.2.14
                included

awplus(config)# snmp-server view atmib alliedtelesis
                included
```

Step 3: Add SNMP group.

```
awplus(config)# snmp-server group ord-user noauth read
                atmib

awplus(config)# snmp-server group admin-user auth read
                atmib write atmib notify atmi
```

Step 4: Add SNMP users.

Add users to the groups by using commands such as:

```
awplus(config)# snmp-server user ken admin-user auth md5
                mercury
```

Step 5: Add SNMP target parameters.

Step 6: Add SNMP target address.

Using SNMP to Manage Files and Software

The Allied Telesis Enterprise MIB (Chapter 89, SNMP MIBs) includes objects for managing files and software on the switch. This section includes procedures for using MIB objects on the switch to perform some common tasks, via an SNMP management application:

- "Copy a File to or from a TFTP Server" on page 87.21
- "Upgrade Software and Configuration Files" on page 87.23

For more details about the Allied Telesis Enterprise MIB and public MIBs on the switch, see Chapter 89, SNMP MIBs.

Copy a File to or from a TFTP Server

Use this procedure to copy a file (for example, a software version file) to the switch from a TFTP server, or to copy a file (for example, a configuration file) from the switch to a TFTP server. The MIB objects in this procedure reside in the module atFilev2 { modules 600 }, with object ID 1.3.6.1.4.1.207.8.4.4.4.600. For detailed descriptions of the MIB objects used in this procedure, and other file management MIB objects, see "AT-FILEv2-MIB" on page 89.56. Other MIB objects can be used in a similar way for moving and deleting files on the switch.

Table 87-5: Procedure for copying a file to or from a device using a TFTP server

	Do this ...	By setting or reading this MIB object ...	Whose object ID is ...	To this value...
1.	If the source device is part of a stack, set the stack ID. For a standalone switch, keep the default value, 1.	atFilev2SourceStackId	{ atFilev2Operation 1 }	<*stack-id*>
2.	If the destination device is part of a stack, set the stack ID.	atFilev2DestinationStackId	{ atFilev2Operation 4 }	<*stack-id*>
3.	Set the source device.	atFilev2SourceDevice	{ atFilev2Operation 2 }	1 (TFTP) or 2 (Flash)
4.	Set the destination device.	atFilev2DestinationDevice	{ atFilev2Operation 5 }	1 (TFTP) or 2 (Flash)
5.	Set the source filename. Include the path (if any) but not the device.	atFilev2SourceFileName	{ atFilev2Operation 3 }	<*source-filename*> e.g. /awp/config/admin.cfg
6.	Set the destination filename. Include the path (if any) but not the device.	atFilev2DestinationFileName	{ atFilev2Operation 6 }	<*dest-filename*> e.g. /config/admin.cfg

Table 87-5: Procedure for copying a file to or from a device using a TFTP server

	Do this ...	By setting or reading this MIB object ...	Whose object ID is ...	To this value...
7.	Set the IP address of the TFTP server.	atFilev2TftpIPAddr	{ atFilev2Tftp_4 1 }	*<ip-addr>*
8.	Check that no other transfer is in progress, and that the required parameters have been set.	atFilev2CopyBegin	{ atFilev2Operation 7 }	Read: idle
9.	Start the file transfer.	atFilev2CopyBegin	{ atFilev2Operation 7 }	Set: 1
10.	Monitor file transfer progress.	atFilev2CopyBegin	{ atFilev2Operation 7 }	Read: In progress: copying *<src>* --> *<dst>* *or* Success: copy *<src>* --> *<dst>* success *or* Failure: copy *<src>* --> *<dst>* failure: *<err-msg>*

Upgrade Software and Configuration Files

Use this procedure to upgrade to a new software version and boot configuration file. For detailed descriptions of the MIB objects used in this procedure, and other MIB objects for managing software installation and configuration files, see "AT-SETUP-MIB" on page 89.37.

Table 87-6: Procedure for upgrading to a new software version and boot configuration

	Do this ...	By reading or setting this MIB object ...	Whose object ID is ...	To this value...
1.	Check that you have enough flash memory for the currently running software file, the new software version file, and any configuration scripts required.			
2.	Check the version and name of the software currently running.	currSoftVersion currSoftName	1.3.6.1.4.1.207.8.4.4.4.500.2.1.1 1.3.6.1.4.1.207.8.4.4.4.500.2.1.2	Read: <*software-name*> <*software-version*>
3.	If you do not already have the currently running software as a software version file in flash, save the currently running software with a file name to the flash root.	currSoftSaveAs	1.3.6.1.4.1.207.8.4.4.4.500.2.1.1	Set: <*backup-filename.rel*>
4.	Check that the file saved successfully. (The most common failures result from lack of flash memory space.)	currSoftSaveAs	1.3.6.1.4.1.207.8.4.4.4.500.2.1.3	Read: saving <*filename*> *or* <*filename*> success *or* <*filename*> failure: <*error-message*>
5.	Copy the new software version file to flash memory on the device	See Table 87-5.		
6.	Set the new release file to be the current release that the device will install and run the next time it restarts. Include the path.	nextBootPath	1.3.6.1.4.1.207.8.4.4.4.500.2.2.2	Set: <*next-filename*> e.g.: `flash:/release.rel`
7.	Check the version of release file set to install next.	nextBootVersion	1.3.6.1.4.1.207.8.4.4.4.500.2.2.1	Read: <*software-version*>
8.	Set the previous release file to be the backup release that the device will install and run if the device fails to boot successfully with the new release file. Include the path.	bckpPath	1.3.6.1.4.1.207.8.4.4.4.500.2.3.2	Set: <*backup-filename*> e.g.: `flash:/release.rel`

Table 87-6: Procedure for upgrading to a new software version and boot configuration(cont.)

	Do this ...	By reading or setting this MIB object ...	Whose object ID is ...	To this value...
9.	Check the version of backup release file.	bckpVersion	1.3.6.1.4.1.207.8.4.4.4.500.2.3.1	Read: *<software-version>*
10.	If necessary, copy a configuration file to the device (Table 87-5), or save the current running configuration to a file in the root directory of flash. To save the running configuration, specify the filename, but not a device or path.	See Table 87-5. or runCnfgSaveAs	1.3.6.1.4.1.207.8.4.4.4.500.3.1.1	Set: *<filename.cfg>* e.g.: myconfig.cfg
11.	Check and if necessary set the file the device will use for configuration when it restarts. Include the full path.	bootCnfgPath	1.3.6.1.4.1.207.8.4.4.4.500.3.2.1	Read/set: *<filename.cfg>* e.g.: flash:/myconfig.cfg
12.	Check that a boot configuration file matching the boot configuration path exists.	bootCnfgExists	1.3.6.1.4.1.207.8.4.4.4.500.3.2.2	Read: TRUE (1) or FALSE (2)
13.	Check that the default configuration file flash:/default.cfg exists.	dfltCnfgExists	1.3.6.1.4.1.207.8.4.4.4.500.3.3.2	Read: TRUE (1) or FALSE (2)
14.	Restart the device.	restartDevice	1.3.6.1.4.1.207.8.4.4.4.500.1	1

Command List

This chapter provides an alphabetical reference for commands used to configure SNMP. For more information, see Chapter 87, SNMP Introduction, and Chapter 89, SNMP MIBs.

For information about modifying or redirecting the output from show commands to a file, see "Controlling "show" Command Output" on page 1.41.

debug snmp

This command enables SNMP debugging.

The no variant of this command disables SNMP debugging.

Syntax

```
debug snmp [all|detail|error-string|process|receive|send|xdump]
no debug snmp [all|detail|error-string|process|receive|send|xdump]
```

Parameter	Description
`all`	Enable or disable the display of all SNMP debugging information.
`detail`	Enable or disable the display of detailed SNMP debugging information.
`error-string`	Enable or disable the display of debugging information for SNMP error strings.
`process`	Enable or disable the display of debugging information for processed SNMP packets.
`receive`	Enable or disable the display of debugging information for received SNMP packets.
`send`	Enable or disable the display of debugging information for sent SNMP packets.
`xdump`	Enable or disable the display of hexadecimal dump debugging information for SNMP packets.

Mode Privileged Exec and Global Configuration

Example To start SNMP debugging, use the command:

```
awplus# debug snmp
```

To start SNMP debugging, showing detailed SNMP debugging information, use the command:

```
awplus# debug snmp detail
```

To start SNMP debugging, showing all SNMP debugging information, use the command:

```
awplus# debug snmp all
```

Related Commands

show debugging snmp
terminal monitor
undebug snmp

show counter snmp-server

This command displays counters for SNMP messages received by the SNMP agent.

Syntax `show counter snmp-server`

Mode User Exec and Privileged Exec

Example To display the counters for the SNMP agent, use the command:

```
awplus# show counter snmp-server
```

Output Figure 88-1: Example output from the **show counter snmp-server** command

```
SNMP-SERVER counters

```

Table 88-1: Parameters in the output of the **show counter snmp-server** command

Parameter	Meaning
`inPkts`	The total number of SNMP messages received by the SNMP agent.
`inBadVersions`	The number of messages received by the SNMP agent for an unsupported SNMP version. It drops these messages.The SNMP agent on your device supports versions 1, 2C, and 3.

Table 88-1: Parameters in the output of the **show counter snmp-server** command (cont.)

Parameter	Meaning
inBadCommunityNames	The number of messages received by the SNMP agent with an unrecognized SNMP community name. It drops these messages.
inBadCommunityUses	The number of messages received by the SNMP agent where the requested SNMP operation is not permitted from SNMP managers using the SNMP community named in the message.
inASNParseErrs	The number of ASN.1 or BER errors that the SNMP agent has encountered when decoding received SNMP Messages.
inTooBigs	The number of SNMP PDUs received by the SNMP agent where the value of the error-status field is 'tooBig'. This is sent by an SNMP manager to indicate that an exception occurred when processing a request from the agent.
inNoSuchNames	The number of SNMP PDUs received by the SNMP agent where the value of the error-status field is 'noSuchName'. This is sent by an SNMP manager to indicate that an exception occurred when processing a request from the agent.
inBadValues	The number of SNMP PDUs received by the SNMP agent where the value of the error-status field is 'badValue'. This is sent by an SNMP manager to indicate that an exception occurred when processing a request from the agent.
inReadOnlys	The number of valid SNMP PDUs received by the SNMP agent where the value of the error-status field is 'readOnly'. The SNMP manager should not generate a PDU which contains the value 'readOnly' in the error-status field. This indicates that there is an incorrect implementations of the SNMP.
inGenErrs	The number of SNMP PDUs received by the SNMP agent where the value of the error-status field is 'genErr'.
inTotalReqVars	The number of MIB objects that the SNMP agent has successfully retrieved after receiving valid SNMP Get-Request and Get-Next PDUs.
inTotalSetVars	The number of MIB objects that the SNMP agent has successfully altered after receiving valid SNMP Set-Request PDUs.
inGetRequests	The number of SNMP Get-Request PDUs that the SNMP agent has accepted and processed.
inGetNexts	The number of SNMP Get-Next PDUs that the SNMP agent has accepted and processed.
inSetRequests	The number of SNMP Set-Request PDUs that the SNMP agent has accepted and processed.
inGetResponses	The number of SNMP Get-Response PDUs that the SNMP agent has accepted and processed.
inTraps	The number of SNMP Trap PDUs that the SNMP agent has accepted and processed.
outPkts	The number of SNMP Messages that the SNMP agent has sent.

Table 88-1: Parameters in the output of the **show counter snmp-server** command (cont.)

Parameter	Meaning
outTooBigs	The number of SNMP PDUs that the SNMP agent has generated with the value ‘tooBig’ in the error-status field. This is sent to the SNMP manager to indicate that an exception occurred when processing a request from the manager.
outNoSuchNames	The number of SNMP PDUs that the SNMP agent has generated with the value `noSuchName' in the error-status field. This is sent to the SNMP manager to indicate that an exception occurred when processing a request from the manager.
outBadValues	The number of SNMP PDUs that the SNMP agent has generated with the value ‘badValue’ in the error-status field. This is sent to the SNMP manager to indicate that an exception occurred when processing a request from the manager.
outGenErrs	The number of SNMP PDUs that the SNMP agent has generated with the value ‘genErr' in the error-status field. This is sent to the SNMP manager to indicate that an exception occurred when processing a request from the manager.
outGetRequests	The number of SNMP Get-Request PDUs that the SNMP agent has generated.
outGetNexts	The number of SNMP Get-Next PDUs that the SNMP agent has generated.
outSetRequests	The number of SNMP Set-Request PDUs that the SNMP agent has generated.
outGetResponses	The number of SNMP Get-Response PDUs that the SNMP agent has generated.
outTraps	The number of SNMP Trap PDUs that the SNMP agent has generated.
UnSupportedSecLevels	The number of received packets that the SNMP agent has dropped because they requested a securityLevel unknown or not available to the SNMP agent.
NotInTimeWindows	The number of received packets that the SNMP agent has dropped because they appeared outside of the authoritative SNMP agent's window.
UnknownUserNames	The number of received packets that the SNMP agent has dropped because they referenced an unknown user.
UnknownEngineIDs	The number of received packets that the SNMP agent has dropped because they referenced an unknown snmpEngineID.
WrongDigest	The number of received packets that the SNMP agent has dropped because they didn't contain the expected digest value.
DecryptionErrors	The number of received packets that the SNMP agent has dropped because they could not be decrypted.
UnknownSecModels	The number of messages received that contain a security model that is not supported by the server. Valid for SNMPv3 messages only.

Table 88-1: Parameters in the output of the **show counter snmp-server** command (cont.)

Parameter	Meaning
InvalidMsgs	The number of messages received where the security model is supported but the authentication fails. Valid for SNMPv3 messages only.
UnknownPDUHandlers	The number of times the SNMP handler has failed to process a PDU. This is a system debugging counter.

Related Commands show snmp-server

show debugging snmp

This command displays whether SNMP debugging is enabled or disabled.

Syntax

```
show debugging snmp
```

Mode User Exec and Privileged Exec

Example To display the status of SNMP debugging, use the command:

```
awplus# show debugging snmp
```

Output Figure 88-2: Example output from the **show debugging snmp** command

```
Snmp (SMUX) debugging status:
  Snmp debugging is on
```

Related Commands debug snmp

show running-config snmp

This command displays the current configuration of SNMP on your device.

Syntax `show running-config snmp`

Mode Privileged Exec

Example To display the current configuration of SNMP on your device, use the command:

```
awplus# show running-config snmp
```

Output Figure 88-3: Example output from the **show running-config snmp** command

```
snmp-server contact AlliedTelesis
snmp-server location Philippines
snmp-server group grou1 auth read view1 write view1 notify view1
snmp-server view view1 1 included
snmp-server community public
snmp-server user user1 group1 auth md5 password priv des
password
```

Related Commands show snmp-server

show snmp-server

This command displays the status and current configuration of the SNMP server.

Syntax `show snmp-server`

Mode Privileged Exec

Example To display the status of the SNMP server, use the command:

```
awplus# show snmp-server
```

Output Figure 88-4: Example output from the **show snmp-server** command

```
SNMP Server ......................... Enabled
IP Protocol ......................... IPv4
SNMPv3 Engine ID (configured name) ... Not set
SNMPv3 Engine ID (actual) ............ 0x80001f888021338e4747b8e607
```

Related Commands
debug snmp
show counter snmp-server
snmp-server
snmp-server engineID local
snmp-server engineID local reset

show snmp-server community

This command displays the SNMP server communities configured on the device. SNMP communities are specific to v1 and v2c.

Syntax `show snmp-server community`

Mode Privileged Exec

Example To display the SNMP server communities, use the command:

```
awplus# show snmp-server community
```

Output Figure 88-5: Example output from the **show snmp-server community** command

```
SNMP community information:
  Community Name ........... public
    Access ................. Read-only
    View ................... none
```

Related Commands show snmp-server
snmp-server community

show snmp-server group

This command displays information about SNMP server groups. This command is used with SNMP version 3 only.

Syntax `show snmp-server group`

Mode Privileged Exec

Example To display the SNMP groups configured on the device, use the command:

```
awplus# show snmp-server group
```

Output Figure 88-6: Example output from the **show snmp-server group** command

```
SNMP group information:
  Group name ..... guireadgroup
    Security Level ..... priv
    Read View ..... guiview
    Write View ..... none
    Notify View ..... none

  Group name ..... guiwritegroup
    Security Level ..... priv
    Read View ..... none
    Write View ..... guiview
    Notify View ..... none
```

Related Commands show snmp-server
snmp-server group

show snmp-server user

This command displays the SNMP server users and is used with SNMP version 3 only.

Syntax `show snmp-server user`

Mode Privileged Exec

Example To display the SNMP server users configured on the device, use the command:

```
awplus# show snmp-server user
```

Output Figure 88-7: Example output from the **show snmp-server user** command

```
Name            Group name          Auth        Privacy
-------         -------------       -------     ----------
freddy          guireadgroup        none        none
```

Related Commands show snmp-server
snmp-server user

show snmp-server view

This command displays the SNMP server views and is used with SNMP version 3 only.

Syntax `show snmp-server view`

Mode Privileged Exec

Example To display the SNMP server views configured on the device, use the command:

```
awplus# show snmp-server view
```

Output Figure 88-8: Example output from the **show snmp-server view** command

```
SNMP view information:
  View Name ............... view1
    OID ..................... 1
    Type .................... included
```

Related Commands show snmp-server
snmp-server view

snmp trap link-status

Use this command to enable SNMP to send link status notifications (traps) for the interfaces when an interface goes up (linkUp) or down (linkDown).

Use the no variant of this command to disable the sending of link status notifications.

Syntax

```
snmp trap link-status
no snmp trap link-status
```

Default By default, link status notifications are disabled.

Mode Interface Configuration

Usage The link status notifications can be enabled for the following interface types:

- switch port (e.g. port 1.0.1)
- VLAN (e.g. vlan2)
- Ethernet (e.g. eth0)
- static and dynamic link aggregation (e.g. sa2, po3)

To specify where notifications are sent, use the snmp-server host command on page 88.23. To configure the switch globally to send other notifications, use the snmp-server enable trap command on page 88.17.

Examples To enable SNMP to send link status notifications for ports 1.0.2 to 1.0.12, use following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2-1.0.12
awplus(config-if)# snmp trap link-status
```

To disable the sending of link status notifications for port 1.0.2, use following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no snmp trap link-status
```

Related Commands

show interface
snmp trap link-status suppress
snmp-server enable trap
snmp-server host

snmp trap link-status suppress

Use this command to enable the suppression of link status notifications (traps) for the interfaces beyond the specified threshold, in the specified interval.

Use the no variant of this command to disable the suppression of link status notifications for the ports.

Syntax

```
snmp trap link-status suppress
   {time {<1-60>|default}|threshold {<1-20>|default}}

no snmp trap link-status suppress
```

Parameter	Description
`time`	Set the suppression timer for link status notifications.
<1-60>	The suppress time in seconds.
`default`	The default suppress time in seconds (60).
`threshold`	Set the suppression threshold for link status notifications. This is the number of link status notifications after which to suppress further notifications within the suppression timer interval.
<1-20>	The number of link status notifications.
`default`	The default number of link status notifications (20).

Default By default, if link status notifications are enabled (they are enabled by default), the suppression of link status notifications is enabled: notifications that exceed the notification threshold (default 20) within the notification timer interval (default 60 seconds) are not sent.

Mode Interface Configuration

Usage An unstable network can generate many link status notifications. When notification suppression is enabled, a suppression timer is started when the first link status notification of a particular type (linkUp or linkDown) is sent for an interface. If the threshold number of notifications of this type is sent before the timer reaches the suppress time, any further notifications of this type generated for the interface during the interval are not sent. At the end of the interval, the sending of link status notifications resumes, until the threshold is reached in the next interval.

Examples To enable the suppression of link status notifications for ports 1.0.2 to 1.0.12 after 10 notifications have been sent in 40 seconds, use following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2-1.0.12
awplus(config-if)# snmp trap link-status suppress time 40
                   threshold 10
```

To disable the suppression link status notifications for port 1.0.2, use following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no snmp trap link-status suppress
```

Related Commands
show interface
snmp trap link-status

snmp-server

Use this command to enable the SNMP agent (server) on the switch. The SNMP agent receives and processes SNMP packets sent to the switch, and generates notifications (traps) that have been enabled by the snmp-server enable trap command on page 88.17.

Use the no variant of this command to disable the SNMP agent on the switch. When SNMP is disabled, SNMP packets received by the switch are discarded, and no notifications are generated. This does not remove any existing SNMP configuration.

Syntax

```
snmp-server [ip|ipv6]
no snmp-server [ip|ipv6]
```

Parameter	Description
ip	Enable or disable the SNMP agent for IPv4.
ipv6	Enable or disable the SNMP agent for IPv6.

Default By default, the SNMP agent is enabled for both IPv4 and IPv6. If neither the ip parameter nor the ipv6 parameter is specified for this command, then SNMP is enabled or disabled for both IPv4 and IPv6.

Mode Global Configuration

Examples To enable SNMP on the switch for both IPv4 and IPv6, use the commands:

```
awplus# configure terminal
awplus(config)# snmp-server
```

To enable the SNMP agent for IPv4 on the device, use the commands:

```
awplus# configure terminal
awplus(config)# snmp-server ip
```

To disable the SNMP agent for both IPv4 and IPv6 on the switch, use the commands:

```
awplus# configure terminal
awplus(config)# no snmp-server
```

To disable the SNMP agent for IPv4, use the commands:

```
awplus(config)# no snmp-server ipv4
```

Related Commands
show snmp-server
show snmp-server community
show snmp-server user
snmp-server community

snmp-server contact
snmp-server enable trap
snmp-server engineID local
snmp-server group
snmp-server host
snmp-server location
snmp-server view

snmp-server community

This command creates an SNMP community, optionally setting the access mode for the community. The default access mode is read only. If view is not specified, the community allows access to all the MIB objects. The SNMP communities are only valid for SNMPv1 and v2c and provide very limited security. Communities should not be used when operating SNMPv3.

The no variant of this command removes an SNMP community. The specified community must already exist on the device.

Syntax

```
snmp-server community <community-name>
    {view <view-name>|ro|rw|<access-list>}

no snmp-server community <community-name> [{view <view-name>|<access-
    list>}]
```

Parameter	Description
`<community-name>`	Community name. The community name is a string up to 20 characters long and is case sensitive.
`view`	Configure SNMP view. If view is not specified, the community allows access to all the MIB objects.
`<view-name>`	View name. The view name is a string up to 20 characters long and is case sensitive.
`ro`	Read-only community.
`rw`	Read-write community.
`<access-list>`	*<1-99>* Access list number.

Mode Global Configuration

Example The following command creates an SNMP community called "public" with read only access to all MIB variables from any management station.

```
awplus# configure terminal
awplus(config)# snmp-server community public ro
```

The following command removes an SNMP community called "public"

```
awplus# configure terminal
awplus(config)# no snmp-server community public
```

Related Commands

show snmp-server
show snmp-server community
snmp-server view

snmp-server contact

This command sets the contact information for the system. The contact name is:

- displayed in the output of the show system command
- stored in the MIB object sysContact

The no variant of this command removes the contact information from the system.

Syntax

```
snmp-server contact <contact-info>
no snmp-server contact
```

Parameter	Description
<contact-info>	The contact information for the system, from 0 to 255 characters long. Valid characters are any printable character and spaces.

Mode Global Configuration

Example To set the system contact information to “support@alliedtelesis.co.nz”, use the command:

```
awplus# configure terminal
awplus(config)# snmp-server contact support@alliedtelesis.co.nz
```

Related Commands

show system
snmp-server location
snmp-server group

snmp-server enable trap

Use this command to enable the switch to send the specified notifications (traps).

Note that the Environmental Monitoring traps are enabled by default. So you do not need to issue this command for the Environmental Monitoring traps since these are enabled by default. SNMP environmental monitoring traps defined in AT-ENVMONv2-MIB are enabled by default.

Use the no variant of this command to disable the sending of the specified notifications.

Syntax

```
snmp-server enable trap {[auth] [bgp] [dhcpsnooping] [epsr] [lldp]
    [loopprot] [mstp] [nsm] [ospf] [pim] [rmon] [vcs] [vrrp]}

no snmp-server enable trap {[auth] [bgp] [dhcpsnooping] [epsr] [lldp]
    [loopprot] [mstp] [nsm] [ospf] [pim] [rmon] [vcs] [vrrp]}
```

Parameter	Description
`auth`	Authentication failure.
`bgp`	BGP traps.
`dhcpsnooping`	DHCP snooping and ARP security traps. These notifications must also be set using the ip dhcp snooping violation command on page 78.22, and/or the arp security violation command on page 78.3.
`epsr`	EPSR traps.
`lldp`	Link Layer Discovery Protocol (LLDP) traps. These notifications must also be enabled using the lldp notifications command on page 91.13, and/or the lldp med-notifications command on page 91.8.
`loopprot`	Loop Protection traps.
`mstp`	MSTP traps.
`nsm`	NSM traps.
`ospf`	OSPF traps.
`pim`	PIM traps.
`rmon`	RMON traps.
`vcs`	VCS traps.
`vrrp`	Virtual Router Redundancy (VRRP) traps.

Default By default, no notifications are generated.

Mode Global Configuration

Usage This command cannot be used to enable link status notifications globally. To enable link status notifications for particular interfaces, use the snmp trap link-status command.

To specify where notifications are sent, use the snmp-server host command.

Examples To enable the device to send OSPF and VRRP-related traps, use the following commands:

```
awplus# configure terminal
awplus(config)# snmp-server enable trap ospf vrrp
```

To disable OSPF traps being sent out by the switch, use the following commands:

```
awplus# configure terminal
awplus(config)# no snmp-server enable trap ospf
```

Related Commands
show snmp-server
show ip dhcp snooping
snmp trap link-status
snmp-server host

snmp-server engineID local

Use this command to configure the SNMPv3 engine ID. The SNMPv3 engine ID is used to uniquely identify the SNMPv3 agent on a switch when communicating with SNMP management clients. Once an SNMPv3 engine ID is assigned, this engine ID is permanently associated with the switch until you change it.

Use the no variant of this command to set the user defined SNMPv3 engine ID to a system generated pseudo-random value by resetting the SNMPv3 engine. The no snmp-server engineID local command has the same effect as the snmp-server engineID local default command. Note that the snmp-server engineID local reset command is used to force the system to generate a new engine ID when the current engine ID is also system generated.

Syntax

```
snmp-server engineID local {<engine-id>|default}
no snmp-server engineID local
```

Parameter	Description
<engine-id>	Specify SNMPv3 Engine ID value, a string of up to 27 characters.
`default`	Set SNMPv3 engine ID to a system generated value by resetting the SNMPv3 engine, provided the current engine ID is user defined. If the current engine ID is system generated, use the snmp-server engineID local reset command to force the system to generate a new engine ID.

Mode Global Configuration

Usage All switches must have a unique engine ID which is permanently set unless it is configured by the user.

In a stacked environment, if the same engine ID was automatically generated for all members of the stack, conflicts would occur if the stack was dismantled. Therefore, each member of the stack will generate its own engine ID and the stack master's ID is used when transmitting SNMPv3 packets. Should a master failover occur, a different engine ID is transmitted. You can modify this behavior by manually assigning all stack members the same engine ID using the snmp-server engineID local command. However, should you decide to separate the stack and use the switches individually, you must remember to change or remove this configuration to prevent conflicts.

Example To set the SNMPv3 engine ID to 800000cf030000cd123456, use the following commands:

```
awplus# configure terminal
awplus(config)# snmp-server engineID local
800000cf030000cd123456
```

To set a user defined SNMPv3 engine ID back to a system generated value, use the following commands:

```
awplus# configure terminal
awplus(config)# no snmp-server engineID local
```

Output The following example shows the engine ID values after configuration:

```
awplus(config)#snmp-server engineid local asdgdfh231234d
awplus(config)#exit
awplus#show snmp-server

SNMP Server ........................... Enabled
IP Protocol ........................... IPv4
SNMPv3 Engine ID (configured name) ... asdgdfh231234d
SNMPv3 Engine ID (actual) ............. 0x80001f888029af52e149198483

awplus(config)#no snmp-server engineid local
awplus(config)#exit
awplus#show snmp-server

SNMP Server ........................... Enabled
IP Protocol ........................... IPv4
SNMPv3 Engine ID (configured name) ... Not set
SNMPv3 Engine ID (actual) ............. 0x80001f888029af52e149198483
```

Validation Commands show snmp-server

Related Commands snmp-server engineID local reset
snmp-server group

snmp-server engineID local reset

Use this command to force the switch to generate a new pseudo-random SNMPv3 engine ID by resetting the SNMPv3 engine. If the current engine ID is user defined, use the snmp-server engineID local command to set SNMPv3 engine ID to a system generated value.

Syntax `snmp-server engineID local reset`

Mode Global Configuration

Example To force the SNMPv3 engine ID to be reset to a system generated value, use the commands:

```
awplus# configure terminal
awplus(config)# snmp-server engineID local reset
```

Validation Commands show snmp-server

Related Commands snmp-server engineID local

snmp-server group

This command is used with SNMP version 3 only, and adds an SNMP group, optionally setting the security level and view access modes for the group. The security and access views defined for the group represent the minimum required of its users in order to gain access.

The no variant of this command deletes an SNMP group, and is used with SNMPv3 only. The group with the specified authentication/encryption parameters must already exist.

Syntax

```
snmp-server group <groupname> {auth|noauth|priv}
   [read <readname>|write <writename>|notify <notifyname>]

no snmp-server group <groupname> {auth|noauth|priv}
```

Parameter	Description
<groupname>	Group name. The group name is a string up to 20 characters long and is case sensitive.
`auth`	Authentication.
`noauth`	No authentication and no encryption.
`priv`	Authentication and encryption.
`read`	Configure read view.
<readname>	Read view name.
`write`	Configure write view.
<writename>	Write view name. The view name is a string up to 20 characters long and is case sensitive.
`notify`	Configure notify view.
<notifyname>	Notify view name. The view name is a string up to 20 characters long and is case sensitive.

Mode Global Configuration

Examples To add SNMP group, for ordinary users, user the following commands:

```
awplus# configure terminal
awplus(config)# snmp-server group usergroup noauth read
                useraccess write useraccess
```

To delete SNMP group `usergroup`, use the following commands

```
awplus# configure terminal
awplus(config)# no snmp-server group usergroup noauth
```

Related Commands

snmp-server
show snmp-server
show snmp-server group
show snmp-server user

snmp-server host

This command specifies an SNMP trap host destination to which Trap or Inform messages generated by the device are sent.

For SNMP version 1 and 2c you must specify the community name parameter. For SNMP version 3, specify the authentication/encryption parameters and the user name. If the version is not specified, the default is SNMP version 1. Inform messages can be sent instead of traps for SNMP version 2c and 3.

Use the no variant of this command to remove an SNMP trap host. The trap host must already exist.

The trap host is uniquely identified by:

- host IP address (IPv4 or IPv6),
- inform or trap messages,
- community name (SNMPv1 or SNMP v2c) or the authentication/encryption parameters and user name (SNMP v3).

Syntax

```
snmp-server host {<ipv4-address>|<ipv6-address>} [traps] [version 1]
   <community-name>]

snmp-server host {<ipv4-address>|<ipv6-address>} [informs|traps]
   version 2c <community-name>

snmp-server host {<ipv4-address>|<ipv6-address>} [informs|traps]
   version 3 {auth|noauth|priv} <user-name>

no snmp-server host {<ipv4-address>|<ipv6-address>} [traps]
   [version 1] <community-name>

no snmp-server host {<ipv4-address>|<ipv6-address>} [informs|traps]
   version 2c <community-name>

no snmp-server host {<ipv4-address>|<ipv6-address>} [informs|traps]
   version 3 {auth|noauth|priv} <user-name>
```

Parameter	Description
<ipv4-address>	IPv4 trap host address in the format A.B.C.D, for example, 192.0.2.2.
<ipv6-address>	IPv6 trap host address in the format x:x::x:x for example, 2001:db8::8a2e:7334.
informs	Send Inform messages to this host.
traps	Send Trap messages to this host (default).
version	SNMP version to use for notification messages. Default: version 1.
1	Use SNMPv1(default).
2c	Use SNMPv2c.
3	Use SNMPv3.
auth	Authentication.
noauth	No authentication.

Parameter(cont.)	Description(cont.)
`priv`	Encryption.
`<community-name>`	The SNMPv1 or SNMPv2c community name.
`<user-name>`	SNMPv3 user name.

Mode Global Configuration

Examples To configure the device to send generated traps to the IPv4 host destination `192.0.2.5` with the SNMPv2c community name *public*, use the following command:

```
awplus# configure terminal
awplus(config)# snmp-server host 192.0.2.5 version 2c public
```

To configure the device to send generated traps to the IPv6 host destination `2001:db8::8a2e:7334` with the SNMPv2c community name *private*, use the following command:

```
awplus# configure terminal
awplus(config)# snmp-server host 2001:db8::8a2e:7334 version 2c
private
```

To remove a configured trap host of 192.0.2.5 with the SNMPv2c community name *public*, use the following command:

```
awplus# configure terminal
awplus(config)# no snmp-server host 192.0.2.5 version 2c public
```

Related Commands
snmp trap link-status
snmp-server enable trap
snmp-server view

snmp-server location

This command sets the location of the system. The location is:

- displayed in the output of the show system command
- stored in the MIB object sysLocation

The no variant of this command removes the configured location from the system.

Syntax

```
snmp-server location <location-name>
no snmp-server location
```

Parameter	Description
<location-name>	The location of the system, from 0 to 255 characters long. Valid characters are any printable character and spaces.

Mode Global Configuration

Example To set the location to “server room 523”, use the following commands:

```
awplus# configure terminal
awplus(config)# system location server room 523
```

Related Commands

show snmp-server
show system
snmp-server contact

snmp-server source-interface

Use this command to specify the interface that SNMP traps or informs originate from. You cannot specify an interface that does not already have an IP address assigned to the interface.

Use the no variant of this command to reset to the default source interface that SNMP traps or informs originate from (the Egress interface as sent from by default).

Syntax

```
snmp-server source-interface {traps|informs} <interface-name>
no snmp-server source-interface {traps|informs}
```

Parameter	Description
`traps`	SNMP traps.
`informs`	SNMP informs.
`<interface-name>`	Interface name (with an IP address already assigned).

Default By default the source interface is the Egress interface where traps or informs were sent from.

Mode Global Configuration

Usage An SNMP trap or inform sent from an SNMP server has the notification IP address of the interface where it was sent from. Use this command to monitor notifications from an interface.

Example To set the interface that SNMP informs originate from to port 1.0.2 for inform packets, use the following commands:

```
awplus# configure terminal
awplus(config)# snmp-server source-interface informs port1.0.2
```

To reset the interface to the default source interface (the Egress interface) that SNMP traps originate from for trap packets, use the following commands:

```
awplus# configure terminal
awplus(config)# no snmp-server source-interface traps
```

Validation Commands show running-config

snmp-server user

Use this command to create or move users as members of specified groups. This command is used with SNMPv3 only.

The no variant of this command removes an SNMPv3 user. The specified user must already exist.

Syntax

```
snmp-server user <username> <groupname> [encrypted]
   [auth {md5|sha} <auth-password>]
   [priv {des|aes} <privacy-password>]

no snmp-server user <username>
```

Parameter	Description
<username>	User name. The user name is a string up to 20 characters long and is case sensitive.
<groupname>	Group name. The group name is a string up to 20 characters long and is case sensitive.
encrypted	Use the encrypted parameter when you want to enter encrypted passwords.
auth	Authentication protocol.
md5	MD5 Message Digest Algorithms.
sha	SHA Secure Hash Algorithm.
<auth-password>	Authentication password. The password is a string of 8 to 20 characters long and is case sensitive.
priv	Privacy protocol.
des	DES Data Encryption Standard.
aes	AES Advanced Encryption Standards.
<privacy-password>	Privacy password. The password is a string of 8 to 20 characters long and is case sensitive.

Mode Global Configuration

Usage Additionally this command provides the option of selecting an authentication protocol and (where appropriate) an associated password. Similarly, options are offered for selecting a privacy protocol and password.

- Note that each SNMP user must be configured on both the manager and agent entities. Where passwords are used, these passwords must be the same for both entities.
- Use the encrypted parameter when you want to enter already encrypted passwords in encrypted form as displayed in the running and startup configs stored on the switch. For example, you may need to move a user from one group to another group and keep the same passwords for the user instead of removing the user to apply new passwords.
- User passwords are entered using plaintext without the encrypted parameter and are encrypted according to the authentication and privacy protocols selected.
- User passwords are viewed as encrypted passwords in running and startup configs shown

from show running-config and show startup-config commands respectively. Copy and paste encrypted passwords from running-configs or startup-configs to avoid entry errors.

Examples To add SNMP user `authuser` as a member of group `usergroup`, with authentication protocol `md5`, authentication password `Authpass`, privacy protocol `des` and privacy password `Privpass`, use the following commands

```
awplus# configure terminal
awplus(config)# snmp-server user authuser usergroup auth md5
Authpass priv des Privpass
```

Validate the user is assigned to the group using the following command:

```
awplus#show snmp-server user
Name                Group name          Auth         Privacy
-------             -------------       -------      ----------
authuser            usergroup           md5          des
```

To enter existing SNMP user `authuser` with existing passwords as a member of group `newusergroup` with authentication protocol `md5` plus the encrypted authentication password `0x1c74b9c22118291b0ce0cd883f8dab6b74`, privacy protocol `des` plus the encrypted privacy password `0x0e0133db5453ebd03822b004eeacb6608f`, use the following commands

```
awplus# configure terminal
awplus(config)# snmp-server user authuser newusergroup
encrypted auth md5
0x1c74b9c22118291b0ce0cd883f8dab6b74 priv des
0x0e0133db5453ebd03822b004eeacb6608f
```

Note Copy and paste the encrypted passwords from the running-config or the startup-config displayed, using the show running-config and show startup-config commands respectively, into the command line to avoid key stroke errors issuing this command.

Validate the user has been moved from the first group using the following command:

```
awplus#show snmp-server user
Name                Group name          Auth         Privacy
-------             -------------       -------      ----------
authuser            newusergroup        md5          des
```

To delete SNMP user `authuser`, use the following commands:

```
awplus# configure terminal
awplus(config)# no snmp-server user authuser
```

Related Commands show snmp-server user
snmp-server view

snmp-server view

Use this command to create an SNMP view that specifies a sub-tree of the MIB. Further sub-trees can then be added by specifying a new OID to an existing view. Views can be used in SNMP communities or groups to control the remote manager's access.

Note The object identifier must be specified in a sequence of integers separated by decimal points.

The no variant of this command removes the specified view on the device. The view must already exist.

Syntax

```
snmp-server view <view-name> <mib-name> {included|excluded}
no snmp-server view <view-name>
```

Parameter	Description
<view-name>	SNMP server view name. The view name is a string up to 20 characters long and is case sensitive.
<mib-name>	Object identifier of the MIB.
included	Include this OID in the view.
excluded	Exclude this OID in the view.

Mode Global Configuration

Examples The following command creates a view called "loc" that includes system location mib sub-tree.

```
awplus(config)# snmp-server view loc 1.3.6.1.2.1.1.6.0 included
```

To remove the view "loc" use the following command

```
awplus(config)# no snmp-server view loc
```

Related Commands show snmp-server view
snmp-server community

undebug snmp

This command applies the functionality of the no debug snmp command.

Introduction

This chapter describes the Management Information Bases (MIBs) and managed objects supported by the AlliedWare Plus™ Operating System. The following topics are covered:

- "Allied Telesis Enterprise MIB" on page 89.5 describes the objects implemented in the Allied Telesis Enterprise MIB
- "Public MIBs" on page 89.66 describes the public MIBs supported by the AlliedWare Plus™ Operating System, and any variations from the standard implementation.

About MIBs

A MIB is a collection of managed objects organized into a tree-like hierarchy of nodes in which the managed objects form the leaves. Within the tree, each node is identified by a non-negative integer identifier that is unique among the node's siblings. The address, or object identifier, of any node within the tree is expressed as a series of dot-delimited node identifiers that trace the path from the root of the tree to the node. For example, the object identifier for the sysDescr object is 1.3.6.1.2.1.1.1.

For more information about MIBs and the structure of management information, see Chapter 87, SNMP Introduction.

About SNMP

A network management station (NMS) uses a protocol known as Simple Network Management Protocol (SNMP) to query or change the values of objects in the MIB of managed devices.

A managed device uses SNMP to respond to queries from an NMS, and to send unsolicited alerts (traps) to an NMS in response to events.

For more information about the Simple Network Management Protocol (SNMP), see Chapter 87, SNMP Introduction.

For information about configuring SNMP, see Chapter 88, SNMP Commands.

Obtaining MIBs

You can download MIBs from the following locations:

Download this MIB...	From this location...
Allied Telesis Enterprise MIB	The MIB files are available with the software files from the Support area at http://www.alliedtelesis.com.
Public MIBs defined in RFCs	http://www.rfc-editor.org/rfc.html
IANAifType-MIB	http://www.iana.org/assignments/ianaiftype-mib

Loading MIBs

Individual MIBs define a portion of the total MIB for a device. For example, the MAU-MIB defines objects for managing IEEE 802.3 medium attachment units (MAUs), and forms a sub-tree under mib-2 with the object identifier snmpDot3MauMgt (1.3.6.1.2.1.26).

All the objects within a MIB are assigned object identifiers relative to a parent object. Most MIBs import the object identifier of the parent object, along with other object identifiers, textual conventions, macros and syntax types from the MIBs where they are defined. This creates dependencies between MIBs.

Some network management stations and MIB compilers will generate errors if you load a MIB that depends on another MIB that has not already been loaded. To avoid these errors, we recommend that you load MIBs in the following order:

1. RFC 1212
   RFC 1239
   RFC 2257
   RFC 3410

2. RFC1155-SMI (RFC 1155)
   SNMPv2-SMI (RFC 2578)
   SNMPv2-PDU (RFC 3416)

3. RFC1213-MIB (RFC 1213)
   RFC 1215
   SNMPv2-TC (RFC 2579)
   SNMPv2-CONF (RFC 2580)

4. IP-MIB (RFC 2011)
   TCP-MIB (RFC 2012)
   UDP-MIB (RFC 2013)
   IP-FORWARD-MIB (RFC 2096)
   SNMP-MPD-MIB (RFC 2572)
   RMON-MIB (RFC 2819)
   HCNUM-TC (RFC 2856)
   SNMP-FRAMEWORK-MIB (RFC 3411)
   SNMP-MPD-MIB (RFC 3412)
   SNMPv2-TM (RFC 3417)
   SNMPv2-MIB (RFC 3418)
   INET-ADDRESS-MIB (RFC 4001)
   IANAifType-MIB

5. IF-MIB (RFC 2863)
   SNMP-TARGET-MIB (RFC 3413)

6. SNMP-COMMUNITY-MIB (RFC 2576)
   EtherLike-MIB (RFC 3635)
   MAU-MIB (RFC 3636)
   BRIDGE-MIB (RFC 4188)
   DISMAN-PING-MIB (RFC 4560)
   SNMP-NOTIFICATION-MIB (RFC 3413)
   SNMP-PROXY-MIB (RFC 3413)

7. P-BRIDGE-MIB (RFC 2674)
   Q-BRIDGE-MIB (RFC 2674)
   RSTP-MIB (RFC 4318)

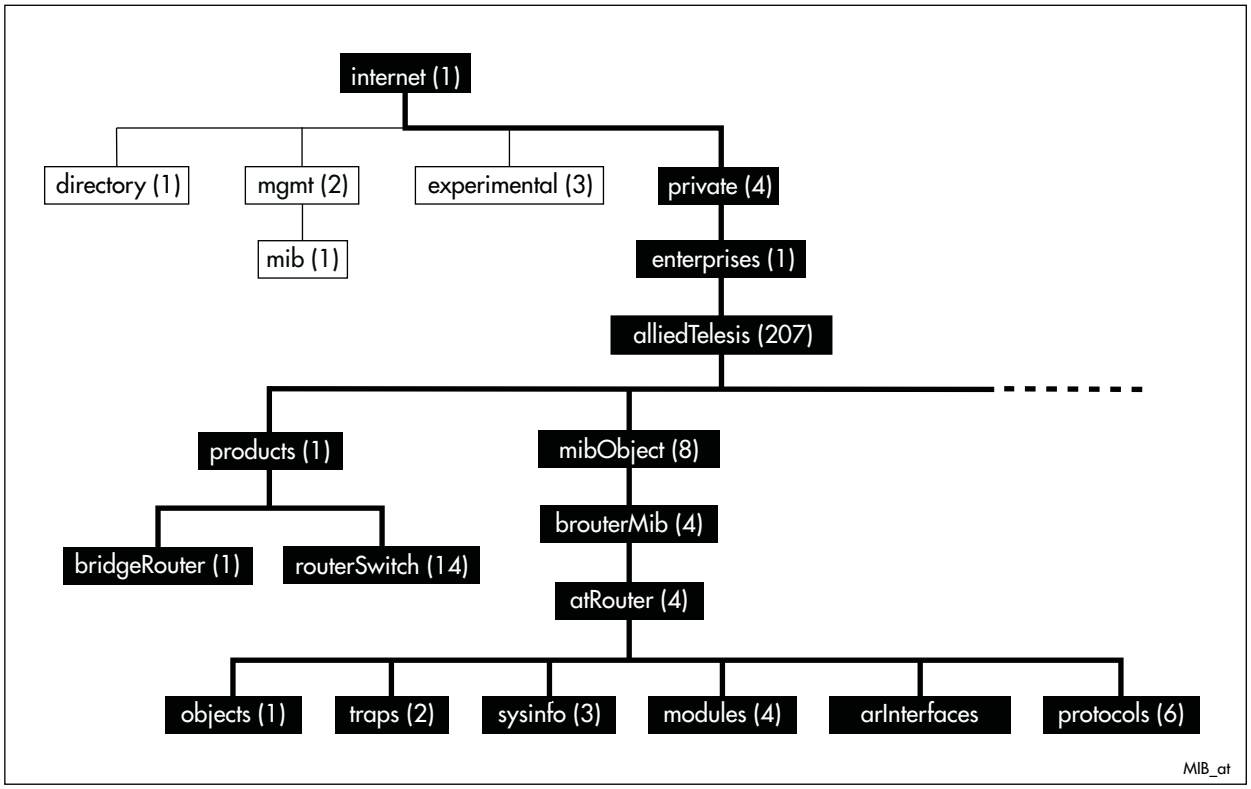
Allied Telesis Enterprise MIB

The *Allied Telesis Enterprise MIB* defines a portion of the Management Information Base (MIB) for managing Allied Telesis products and features that are not supported by public MIBs. Objects defined in this MIB reside in the private(4) subtree and have the object identifier alliedTelesis ({ enterprises 207 }).

This document describes only those portions of the Allied Telesis Enterprise MIB supported by the AlliedWare Plus™ Operating System. Figure 89-1 shows the structure of the Allied Telesis Enterprise MIB. Each component MIB is detailed in the following sections of this chapter.

Figure 89-1: The Allied Telesis Enterprise MIB sub-tree of the Internet-standard Management Information Base (MIB)



AT-SMI-MIB

AT-SMI-MIB defines the high-level structure and root objects of the Allied Telesis Enterprise MIB (Table 89-1). These objects are imported by other component MIBs of the Allied Telesis Enterprise MIB.

Table 89-1: AT Enterprise MIB - High Level Structure

Object	Object Identifier	Description
alliedTelesis	{ enterprises 207 } 1.3.6.1.4.1.207	Root of the Allied Telesis Enterprise MIB under the private(4) node defined in RFC1155-SMI.
products	{ alliedTelesis 1 } 1.3.6.1.4.1.207.1	Sub-tree of all product OIDs. Described in AT-PRODUCT-MIB.
bridgeRouter	{ products 1 } 1.3.6.1.4.1.207.1.1	Sub-tree of bridge product MIB objects (not applicable for AlliedWare Plus).
routerSwitch	{ products 14 } 1.3.6.1.4.1.207.1.2	Sub-tree for all router and switch product MIB objects.
mibObject	{ alliedTelesis 8 } 1.3.6.1.4.1.207.8	Sub-tree for all managed objects.
brouterMib	{ mibObject 4 } 1.3.6.1.4.1.207.8.4	Sub-tree of objects for managing bridges, routers, and switches.
atRouter	{ brouterMib 4 } 1.3.6.1.4.1.207.8.4.4	Sub-tree of objects for managing multiprotocol routers and switches.
objects	{ atRouter 1 } 1.3.6.1.4.1.207.8.4.4.1	Sub-tree of OIDs for boards, releases, interface types, and chips.
traps	{ atRouter 2 } 1.3.6.1.4.1.207.8.4.4.2	Sub-tree for generic traps (not applicable for AlliedWare Plus).
sysinfo	{ atRouter 3 } 1.3.6.1.4.1.207.8.4.4.3	Sub-tree of objects describing general system information.
modules	{ atRouter 4 } 1.3.6.1.4.1.207.8.4.4.4	Sub-tree of objects for monitoring and managing software features.
arInterfaces	{ atRouter 5 } 1.3.6.1.4.1.207.8.4.4.5	Sub-tree of objects describing boards, slots and physical interfaces.
protocols	{ atRouter 6 } 1.3.6.1.4.1.207.8.4.4.6	Sub-tree of OIDs for protocols.
atAgents	{ atRouter 7 } 1.3.6.1.4.1.207.8.4.4.7	Sub-tree of objects describing variations from standards.

Table 89-2 lists the major modules of the AT-SMI-MIB grouped by their object identifiers. Note that this is also the order in which they are described in this chapter.

Table 89-2: AT-SMI-MIBs Listed by Object Group

MIB Section	OID	Description
AT-SMI-MIB		This section describes the structure of management information for the Allied Telesis Enterprise object, alliedTelesis { 1.3.6.1.4.1.207 }.
AT-PRODUCT-MIB	1.3.6.1.4.1.207.1	Object identifiers for Allied Telesis products. See "AT-PRODUCT-MIB" on page 89.9.
AT-BOARDS-MIB	1.3.6.1.4.1.207.8.4.4.1.1	Object identifiers for boards, interface types, and chip sets. See "AT-BOARDS-MIB" on page 89.11.
AT-SYSINFO-MIB	1.3.6.1.4.1.207.8.4.4.3	Objects that describe generic system information and environmental monitoring. See "AT-SYSINFO-MIB" on page 89.14.
AT-XEM-MIB	1.3.6.1.4.1.207.8.4.4.3.11	Objects for managing XEMs (Expansion Modules). See "AT-XEM-MIB" on page 89.16.
AT-ENVMONv2-MIB	1.3.6.1.4.1.207.8.4.4.3.12	Objects and traps for monitoring fans, voltage rails, temperature sensors, and power supply bays. See "AT-ENVMONv2-MIB" on page 89.17.
AT-VCSTACK-MIB	1.3.6.1.4.1.207.8.4.4.3.13	Objects for managing Virtual Chassis Stacking (VCS). See "AT-VCSTACK-MIB" on page 89.22.
AT-MIBVERSION-MIB	1.3.6.1.4.1.207.8.4.4.3.15	Object to display the last software release that contained changes to the support AT Enterprise MIB definition files. See "AT-MIBVERSION-MIB" on page 89.26.
AT-USER-MIB	1.3.6.1.4.1.207.8.4.4.3.20	Objects for displaying information of users currently logged into a device, or configured in the Local User Data base of the device. See "AT-USER-MIB" on page 89.27.
AT-RESOURCE-MIB	1.3.6.1.4.1.207.8.4.4.3.21	Objects for displaying system hardware resource information. See "AT-RESOURCE-MIB" on page 89.29.
AT-LICENSE-MIB	1.3.6.1.4.1.207.8.4.4.3.22	Objects for managing software licenses on devices using AlliedWare Plus™ Operating System. See "AT-LICENSE-MIB" on page 89.30.
AT-TRIGGER-MIB	1.3.6.1.4.1.207.8.4.4.4.53	Objects for managing triggers. See "AT-TRIGGER-MIB" on page 89.33.
AT-LOOPPROTECT-MIB	1.3.6.1.4.1.207.8.4.4.4.54	Objects for managing Allied Telesis Loop Protection. See "AT-LOOPPROTECT-MIB" on page 89.35.
AT-SETUP-MIB	1.3.6.1.4.1.207.8.4.4.4.500	Objects for managing software installation and configuration files. See "AT-SETUP-MIB" on page 89.37.
AT-DNS-CLIENT-MIB	1.3.6.1.4.1.207.8.4.4.4.501	Objects for managing Allied Telesis DNS Client Configuration. See "AT-DNS-CLIENT-MIB" on page 89.47.
AT-NTP-MIB	1.3.6.1.4.1.207.8.4.4.4.502	Objects for managing Allied Telesis Network Time Protocol (NTP) configuration. See "AT-NTP-MIB" on page 89.48.
AT-EPSRv2-MIB	1.3.6.1.4.1.207.8.4.4.4.536	Objects for managing Allied Telesis EPSR. See "AT-EPSRv2-MIB" on page 89.51.
AT-DHCPSN-MIB	1.3.6.1.4.1.207.8.4.4.4.537	Objects for managing Allied Telesis DHCP Snooping. See "AT-DHCPSN-MIB" on page 89.53.
AT-FILEv2-MIB	1.3.6.1.4.1.207.8.4.4.4.600	Objects for displaying and managing file content on local, stacked and remote sources. See "AT-FILEv2-MIB" on page 89.56.

Table 89-2: AT-SMI-MIBs Listed by Object Group(cont.)

MIB Section	OID	Description
AT-LOG-MIB	1.3.6.1.4.1.207.8.4.4.4.601	Objects for listing log entries from the buffered and permanent logs. See "AT-LOG-MIB" on page 89.62.
AT-IP-MIB	1.3.6.1.4.1.207.8.4.4.4.602	Objects for Allied Telesis specific IP address management. See "AT-IP-MIB" on page 89.64.

AT-PRODUCT-MIB

AT-PRODUCT-MIB defines object identifiers for Allied Telesis products. Objects in this MIB have the object identifier products ({ alliedTelesis 1 }). Table 89-3 lists object identifiers for products supported by the AlliedWare Plus™ Operating System.

Table 89-3: Object identifiers for Allied Telesis products supported by the AlliedWare Plus™ Operating System

Object	Object Identifier	Description
at_SwitchBladex908	{ routerSwitch 69 }	Switchblade x908 8 Slot Layer 3 Switch Chassis
at_x900_12XTS	{ routerSwitch 70 }	AT-x900-12XT/S Advanced Gigabit Layer 3+ Expandable Switch, 12 x combo ports (10/100/1000BASE-T copper or SFP), 1 x 30Gbps expansion bay
at_x900_24XT	{ routerSwitch 75 }	x900-24XT Enhanced Gigabit Layer 3+ Expandable Switch, 24 x 10/100/1000BASE-T copper ports (RJ-45 connectors), 2 x 20 Gigabit expansion bays
at_x900_24XS	{ routerSwitch 76 }	x900-24XS Enhanced Gigabit Layer 3+ Expandable Switch, 24 x 10/100/1000BASE-T copper ports (RJ-45 connectors), 2 x 20 Gigabit expansion bays
at_x900_24XT_N	{ routerSwitch 77 }	x900-24XT-N Enhanced Gigabit Layer 3+ Expandable Switch, 24 x 10/100/1000BASE-T copper ports (RJ-45 connectors), 2 x 20 Gigabit expansion bays, NEBS compliant
at_x600_24Ts	{ routerSwitch 80 }	x600-24Ts Stackable Managed L2+/L3 Ethernet Switch, 24 x 1000BASE-T copper ports, 4 x SFP (combo) ports
at_x600_24TsXP	{ routerSwitch 81 }	x600-24Ts/XP Stackable Managed L2+/L3 Ethernet Switch, 24 x 1000BASE-T copper ports, 4 x SFP (combo) ports, 2 x XFP ports
at_x600_48Ts	{ routerSwitch 82 }	x600-48Ts Stackable Managed L2+/L3 Ethernet Switch, 48 x 1000BASE-T copper ports, 4 x SFP ports
at_x600_48TsXP	{ routerSwitch 83 }	x600-48Ts/XP Stackable Managed L2+/L3 Ethernet Switch, 48 x 1000BASE-T copper ports, 4 x SFP ports, 2 x XFP ports
at_x600-24TsPoE	{ routerSwitch 91}	x600-24Ts-POE Stackable Managed L2+/L3 Ethernet PoE Switch, 24 x 1000BASE-T PoE ports, 4 x SFP (combo) ports
at_x600_24TPoEPlus	{routerSwitch 92}	x600-24Ts-POE+ Stackable Managed L2+/L3 Ethernet PoE+ Switch, 24 x 1000BASE-T PoE+ ports, 4 x SFP (combo) ports
x610_48Ts_X_POEPlus	{routerSwitch 93}	x610-48Ts/X-POE+ Stackable Managed L2+/L3 Ethernet PoE+ Switch, 48 x 1000BASE-T PoE+ ports, 2 x SFP (combo) ports, 2 x SFP+ ports
x610_48Ts_POEPlus	{routerSwitch 94}	x610-48Ts-POE+ Stackable Managed L2+/L3 Ethernet PoE+ Switch, 48 x 1000BASE-T PoE+ ports, 4 x SFP (combo) ports
x610_24Ts_X_POEPlus	{routerSwitch 95}	x610-24Ts/X-POE+ Stackable Managed L2+/L3 Ethernet PoE+ Switch, 24 x 1000BASE-T PoE+ ports, 4 x SFP (combo) ports, 2 x SFP+ ports
x610_24Ts_POEPlus	{routerSwitch 96}	x610-24Ts-POE+ Stackable Managed L2+/L3 Ethernet PoE+ Switch, 24 x 1000BASE-T PoE+ ports, 4 x SFP (combo) ports

Table 89-3: Object identifiers for Allied Telesis products supported by the AlliedWare Plus™ Operating

Object	Object Identifier	Description
x610_48Ts_X	{routerSwitch 97}	x610-48Ts/X Stackable Managed L2+/L3 Ethernet Switch, 48 x 1000BASE-T copper ports, 2 x SFP (combo) ports, 2 x SFP+ ports
x610_48Ts	{routerSwitch 98}	x610-48Ts Stackable Managed L2+/L3 Ethernet Switch, 24 x 1000BASE-T copper ports, 4 x SFP (combo) ports
x610_24Ts_X	{routerSwitch 99}	x610-24Ts/X Stackable Managed L2+/L3 Ethernet Switch, 24 x 1000BASE-T copper ports, 4 x SFP (combo) ports, 2 x SFP+ ports
x610_24Ts	{routerSwitch 100}	x610-24Ts Stackable Managed L2+/L3 Ethernet Switch, 24 x 1000BASE-T copper ports, 4 x SFP (combo) ports
x610_24SP_X	{routerSwitch 101}	x610-24SP/X Stackable Managed L2+/L3 Ethernet Switch, 24 x SFP (combo) ports, 2 x SFP+ ports

AT-BOARDS-MIB

AT-BOARDS-MIB defines object identifiers for components of Allied Telesis products—base CPU and expansion boards, interface types, and chip sets. Objects in this MIB have the object identifier objects ({ atRouter 1 }), and are organized into the following groups:

- Base CPU and expansion boards (Table 89-4). These object identifiers are for use with the hrDeviceID object in the Host Resources MIB (see "Public MIBs" on page 89.66).
- Interface types (Table 89-5).
- Chip sets (Table 89-6).

Table 89-4: Object identifiers for base CPU and expansion boards

Object	Object Identifier	Description
boards	{ objects 1 }	
pprx90024XT	{ boards 271 }	x900-24XT Enhanced Gigabit Layer 3+ Expandable Switch, 24 x 10/100/1000BASE-T copper ports (RJ-45 connectors), 2 x 20 Gigabit expansion bays
pprx90024XS	{ boards 272 }	x900-24XS Enhanced Gigabit Layer 3+ Expandable Switch, 24 x 10/100/1000BASE-T copper ports (RJ-45 connectors), 2 x 20 Gigabit expansion bays
pprAtXum10Gi	{ boards 273 }	XEM-1XP Expansion Module, 1 x 10Gbe XFP port
pprAtXum12SFPi	{ boards 274 }	XEM-12S Expansion Module, 12 x SFP Gigabit ports
pprAtXum12Ti	{ boards 275 }	XEM-12T Expansion Module, 12 x 10/100/100BASE-T copper ports (RJ-45 connectors)
pprAtXum12TiN	{ boards 280 }	XEM-12T-N Expansion Module, 12 x 10/100/100BASE-T copper ports (RJ-45 connectors), NEBS compliant
pprx90024XTN	{ boards 281 }	x900-24XT Enhanced Gigabit Layer 3+ Expandable Switch, 24 x 10/100/1000BASE-T copper ports (RJ-45 connectors), 2 x 20 Gigabit expansion bays, NEBS compliant
pprSwitchBladex908	{ boards 282 }	Switchblade x908 8 Slot Layer 3 Switch Chassis
pprx90012XTS	{ boards 288 }	AT-x900-12XT/S Advanced Gigabit Layer 3+ Expandable Switch, 12 x combo ports (10/100/1000BASE-T copper or SFP), 1 x 30Gbps expansion bay
pprAt9524TS	{ boards 290 }	x600-24Ts/XP, 24 x 1000BASE-T ports (RJ45 connectors), 4 x SFP (combo) ports
pprAt9524TSXP	{ boards 291 }	x600-24Ts/XP, 24 x 1000BASE-T ports (RJ45 connectors), 4 x SFP (combo) ports, 2 x XFP ports
pprAt9548TS	{ boards 294 }	x600-44Ts, 44 x 1000BASE-T ports, 4 x SFP ports
pprAt9548TSXP	{ boards 295 }	x600-44Ts/XP, 44 x 1000BASE-T ports, 4 x SFP ports, 2 x XFP ports
pprXem2XP	{ boards 306 }	XEM-2XP Expansion Module, 2 x 10Gbe XFP port
pprATStackXG	{ boards 307 }	x600 Expansion Module, Stacking
pprATEMXP	{ boards 308 }	x600 Expansion Module, 2 x 10G XFP ports
pprATLBM	{ boards 309 }	x600 Expansion Module, loopback
pprAtPWR05DC	{ boards 323 }	AT-PWR05, DC power supply unit for SwitchBlade x908
pprXem2XT	{ boards 325 }	XEM-2XT Expansion Module, 2 x 10Gbe copper XEM port
pprx60024TSPOE	{ boards 326 }	x600-24Ts-POE, 24 x 1000BASE-T PoE ports (RJ45 connectors), 4 x SFP (combo) ports

Table 89-4: Object identifiers for base CPU and expansion boards**(cont.)**

Object	Object Identifier	Description
pprx60024TSPOEPLUS	{ boards 327 }	x600-24Ts-POE+, 24 x 1000BASE-T PoE+ ports (RJ45 connectors), 4 x SFP (combo) ports
pprx61048TsXPOEPlus	{ boards 331 }	x610-48Ts/X-POE+, 48 x 1000BASE-T PoE+ ports (RJ45 connectors), 2 x SFP (combo) ports, 2 x SFP+ ports
pprx61048TsPOEPlus	{ boards 332 }	x610-48Ts-POE+, 48 x 1000BASE-T PoE+ ports (RJ45 connectors), 4 x SFP (combo) ports
pprx61024TsXPOEPlus	{ boards 333 }	x610-24Ts/X-POE+, 24 x 1000BASE-T PoE+ ports (RJ45 connectors), 4 x SFP (combo) ports, 2 x SFP+ ports
pprx61024TsPOEPlus	{ boards 334 }	x610-24Ts-POE+, 24 x 1000BASE-T PoE+ ports (RJ45 connectors), 4 x SFP (combo) ports
pprPWR800	{ boards 336 }	AT-PWR800, 800W power supply unit
pprPWR1200	{ boards 337 }	AT-PWR1200, 1200W power supply unit
pprPWR250	{ boards 338 }	AT-PWR250, 250W power supply unit
pprx61048TsX	{ boards 339 }	x610-48Ts/X, 48 x 1000BASE-T ports (RJ45 connectors), 2 x SFP (combo) ports, 2 x SFP+ ports
pprx61048Ts	{ boards 340 }	x610-48Ts, 48 x 1000BASE-T ports (RJ45 connectors), 4 x SFP (combo) ports
pprx61024TsX	{ boards 341 }	x610-24Ts/X, 24 x 1000BASE-T ports (RJ45 connectors), 4 x SFP (combo) ports, 2 x SFP+ ports
pprx61024Ts	{ boards 342 }	x610-24Ts, 24 x 1000BASE-T ports (RJ45 connectors), 4 x SFP (combo) ports
pprPWR250DC	{ boards 351 }	AT-PWR250DC, 250W DC power supply unit

Table 89-5: Object identifiers for interface types

Object	Object Identifier	Description
iftypes	{ objects 3 }	
ifaceEth	{ iftypes 1 }	Ethernet
ifaceSyn	{ iftypes 2 }	Synchronous
ifaceAsyn	{ iftypes 3 }	Asynchronous
ifaceBri	{ iftypes 4 }	BRI ISDN
ifacePri	{ iftypes 5 }	PRI ISDN
ifacePots	{ iftypes 6 }	POTS (voice)
ifaceGBIC	{ iftypes 7 }	GBIC (Gigabit Interface Converter)

Table 89-6: Object identifiers for chip sets

Object	Object Identifier	Description
chips	{ objects 4 }	
chip68020Cpu	{ chips 1 }	MC68020 CPU
chip68340Cpu	{ chips 2 }	MC68340 CPU
chip68302Cpu	{ chips 3 }	MC68302 CPU
chip68360Cpu	{ chips 4 }	MC68360 CPU
chip860TCpu	{ chips 5 }	MPC860T CPU
chipRtc1	{ chips 21 }	Real Time Clock v1

Table 89-6: Object identifiers for chip sets**(cont.)**

Object	Object Identifier	Description
chipRtc2	{ chips 22 }	Real Time Clock v2
chipRtc3	{ chips 23 }	Real Time Clock v3
chipRtc4	{ chips 24 }	Real Time Clock v4
chipRam1mb	{ chips 31 }	1 MB RAM
chipRam2mb	{ chips 32 }	2 MB RAM
chipRam3mb	{ chips 33 }	3 MB RAM
chipRam4mb	{ chips 34 }	4 MB RAM
chipRam6mb	{ chips 36 }	6 MB RAM
chipRam8mb	{ chips 38 }	8 MB RAM
chipRam12mb	{ chips 42 }	12 MB RAM
chipRam16mb	{ chips 46 }	16 MB RAM
chipRam20mb	{ chips 50 }	20 MB RAM
chipRam32mb	{ chips 62 }	32 MB RAM
chipFlash1mb	{ chips 71 }	1 MB FLASH memory
chipFlash2mb	{ chips 72 }	2 MB FLASH memory
chipFlash3mb	{ chips 73 }	3 MB FLASH memory
chipFlash4mb	{ chips 74 }	4 MB FLASH memory
chipFlash6mb	{ chips 76 }	6 MB FLASH memory
chipFlash8mb	{ chips 78 }	8 MB FLASH memory
chipPem	{ chips 120 }	Processor Enhancement Module

AT-SYSINFO-MIB

AT-SYSINFO-MIB defines objects that describe generic system information and environmental monitoring. Objects in this group have the object identifier sysinfo ({ atRouter 3 }). Table 89-7 lists the objects supported by the AlliedWare Plus™ Operating System.

Table 89-7: Objects defined in AT-SYSINFO-MIB

Object	Object Identifier	Description
sysinfo	{ atRouter 3 }	Subtree containing generic system information.
cpu	{ sysinfo 3 }	A collection of objects containing information about the CPU utilization over different periods of time. All values are expressed as a percentage - integer in range 0 to 100.
cpuUtilisationMax	{ cpu 1 }	Maximum CPU utilization since the device was last restarted.
cpuUtilisationAvg	{ cpu 2 }	Average CPU utilization since the device was last restarted.
cpuUtilisationAvgLastMinute	{ cpu 3 }	Average CPU utilization over the past minute.
cpuUtilisationAvgLast10Seconds	{ cpu 4 }	Average CPU utilization over the past ten seconds.
cpuUtilisationAvgLastSecond	{ cpu 5 }	Average CPU utilization over the past second.
cpuUtilisationAvgMaxLast5Minutes	{ cpu 6 }	Maximum CPU utilization over the last 5 minutes.
cpuUtilisationAvgLast5Minutes	{ cpu 7 }	Average CPU utilization over the past 5 minutes.
atContactDetails	{ sysinfo 5 }	Contact details for Allied Telesis.
memory	{ sysinfo 7 }	A collection of objects and traps for monitoring memory usage and status.
freeMemory	{ memory 1 }	Percentage of free memory still available on device.
totalBuffers	{ memory 2 }	Total number of buffers available on device.
lowMemoryTrap	{ memory 11 }	Notification of low memory, generated when a device's memory is below a certain level. Will display the values in 'freeMemory' and 'totalBuffers'
xem	{ sysinfo 11 }	A collection of objects for monitoring XEMs installed in the device. See "AT-XEM-MIB" on page 89.16.
atEnvMonv2	{ sysinfo 12 }	AT Environment Monitoring v2 MIB for managing and reporting data relating to voltage rails, fan speeds, temperature sensors and power supply units. See "AT-ENVMONv2-MIB" on page 89.17.
vcstack	{ sysinfo 13 }	A collection of objects for managing Virtual Chassis Stacking in AlliedWare Plus™. See "AT-VCSTACK-MIB" on page 89.22.
atPortInfo	{ sysinfo 14 }	Objects containing information about the transceiver of an interface.

Table 89-7: Objects defined in AT-SYSINFO-MIB(cont.)

Object	Object Identifier	Description
atPortInfoTransceiverTable	{ atPortInfo 1 }	A table containing information about the transceiver of an interface. Indexed by: ■ atPortInfoTransceiverifIndex
atPortInfoTransceiverEntry	{ atPortInfoTransceiverTable 1 }	Description of a single transceiver.
atPortInfoTransceiverifIndex	{ atPortInfoTransceiverEntry 1 }	The interface index for the interface represented by this entry.
atPortInfoTransceiverType	{ atPortInfoTransceiverEntry 2 }	The type of transceiver on an interface. Can be one of the following: ■ rj45 (1) ■ sfp-px (2) ■ sfp-bx10 (3) ■ sfp-fx (4) ■ sfp-100base-lx (5) ■ sfp-t (6) ■ sfp-cx (7) ■ sfp-zx-cwdm (8) ■ sfp-lx (9) ■ sfp-sx (10) ■ sfp-oc3-lr (11) ■ sfp-oc3-ir (12) ■ sfp-oc3-mm (13) ■ xfp-srsw (14) ■ xfp-lrlw (15) ■ xfp-erew (16) ■ xfp-sr (17) ■ xfp-lr (18) ■ xfp-er (19) ■ xfp-lrm (20) ■ xfp-sw (21) ■ xfp-lw (22) ■ xfp-ew (23) ■ unknown (24) ■ empty (25)
atPortRenumberEvents	{ atPortInfo 2 }	The number of times that port number values (represented by the dot1dBasePort object in BRIDGE-MIB), have been re-assigned due to stack member leave/join events or XEM hot-swap events, since the system was initialized.

AT-XEM-MIB

AT-XEM-MIB defines objects for managing XEMs (Expansion Modules) installed in the device (Table 89-8). Objects in this group have the object identifier xem ({ sysinfo 11 }) and reside in the sysinfo Group of the Allied Telesis Enterprise MIB.

Table 89-8: Objects defined in AT-XEM-MIB

Object	Object Identifier	Description
xemTraps	{ xem 0 }	Collection of traps generated when a XEM is inserted or removed.
xemInserted	{ xemTraps 1 }	Trap generated when a XEM card is inserted to the device. It returns the objects xemInfoStackId and xemInfoBayId.
xemRemoved	{ xemTraps 2 }	Trap generated when a XEM card is removed from the device. It returns the objects xemInfoStackId and xemInfoBayId.
xemInsertedFail	{ xemTraps 3 }	Trap generated when the insertion of a XEM card into the device fails. It returns the objects xemInfoStackId and xemInfoBayId.
xemNumOfXem	{ xem 1 }	Total number of XEMs installed in the device.
xemInfoTable	{ xem 2 }	Table of information about the XEMs installed in the device, indexed by xemInfoMemberId and xemInfoBayId.
xemInfoEntry	{ xemInfoTable 1 }	Information about a single XEM.
xemInfoMemberId	{ xemInfoEntry 1 }	Stack Member ID in which the XEM is installed.
xemInfoBayId	{ xemInfoEntry 2 }	Number of the XEM bay in which the XEM is installed.
xemInfoXemId	{ xemInfoEntry 3 }	Numeric board identity of the XEM. This information is displayed in the ID column of the SHOW SYSTEM command.
xemInfoBoardType	{ xemInfoEntry 4 }	Board type. For XEMs this is always “Expansion”. This information is displayed in the Board column of the SHOW SYSTEM command.
xemInfoBoardName	{ xemInfoEntry 5 }	Name of the XEM. This information is displayed in the Board Name column of the SHOW SYSTEM command.
xemInfoRevision	{ xemInfoEntry 6 }	Board revision of the XEM. This information is displayed in the Rev column of the SHOW SYSTEM command.
xemInfoSerialNumber	{ xemInfoEntry 7 }	Serial number of the XEM. This information is displayed in the Serial Number column of the SHOW SYSTEM command.

AT-ENVMONv2-MIB

The AT Environment Monitoring v2 MIB (atEnvMonv2-MIB) contains objects for managing and reporting data relating to fans, voltage rails, temperature sensors and power supply units installed in the device (Table 89-9). Objects in this group have the object identifier EnvMonv2 ({ sysinfo 12 }).

Table 89-9: Objects defined in AT-ENVMONV2-MIB

Object / Object Identifier	Description
atEnvMonv2Notifications { atEnvMonv2 0 }	Collection of traps (notification) objects for monitoring fans, voltage rails, temperature sensors, and power supply bays.
atEnvMonv2FanAlarmSetNotify { atEnvMonv2Notifications 1 }	Notification generated when the monitored speed of a fan drops below its lower threshold. It returns the value of: ■ atEnvMonv2FanStackMemberId ■ atEnvMonv2FanBoardIndex ■ atEnvMonv2FanIndex ■ atEnvMonv2FanDescription ■ atEnvMonv2FanLowerThreshold ■ atEnvMonv2FanCurrentSpeed
atEnvMonv2FanAlarmClearedNotify { atEnvMonv2Notifications 2 }	Notification generated when the monitored speed of a fan returns to an acceptable value, the fan having previously been in an alarm condition. It returns the value of: ■ atEnvMonv2FanStackMemberId ■ atEnvMonv2FanBoardIndex ■ atEnvMonv2FanIndex ■ atEnvMonv2FanDescription ■ atEnvMonv2FanLowerThreshold ■ atEnvMonv2FanCurrentSpeed
atEnvMonv2VoltAlarmSetNotify { atEnvMonv2Notifications 3 }	Notification generated when the voltage of a monitored voltage rail, goes out of tolerance by either dropping below its lower threshold, or exceeding its upper threshold. It returns the value of: ■ atEnvMonv2VoltageStackMemberId ■ atEnvMonv2VoltageBoardIndex ■ atEnvMonv2VoltageIndex ■ atEnvMonv2VoltageDescription ■ atEnvMonv2VoltageUpperThreshold ■ atEnvMonv2VoltageLowerThreshold ■ atEnvMonv2VoltageCurrent
atEnvMonv2VoltAlarmClearedNotify { atEnvMonv2Notifications 4 }	Notification generated when the voltage of a monitored voltage rail returns to an acceptable value, having previously been in an alarm condition. It returns the value of: ■ atEnvMonv2VoltageStackMemberId ■ atEnvMonv2VoltageBoardIndex ■ atEnvMonv2VoltageIndex ■ atEnvMonv2VoltageDescription ■ atEnvMonv2VoltageUpperThreshold ■ atEnvMonv2VoltageLowerThreshold ■ atEnvMonv2VoltageCurrent

Table 89-9: Objects defined in AT-ENVMONV2-MIB(cont.)

Object / Object Identifier	Description
atEnvMonv2TempAlarmSetNotify { atEnvMonv2Notifications 5 }	Notification generated when a monitored temperature exceeds its upper threshold. It returns the value of: ■ atEnvMonv2TemperatureStackMemberId ■ atEnvMonv2TemperatureBoardIndex ■ atEnvMonv2TemperatureIndex ■ atEnvMonv2TemperatureDescription ■ atEnvMonv2TemperatureUpperThreshold ■ atEnvMonv2TemperatureCurrent
atEnvMonv2TempAlarmClearedNotify { atEnvMonv2Notifications 6 }	Notification generated when a monitored temperature returns to an acceptable value, having previously been in an alarm condition. It returns the value of: ■ atEnvMonv2TemperatureStackMemberId ■ atEnvMonv2TemperatureBoardIndex ■ atEnvMonv2TemperatureIndex ■ atEnvMonv2TemperatureDescription ■ atEnvMonv2TemperatureUpperThreshold
atEnvMonv2PsbAlarmSetNotify { atEnvMonv2Notifications 7 }	Notification generated when a monitored parameter of a power supply bay device goes out of tolerance. It returns the value of: ■ atEnvMonv2PsbSensorStackMemberId ■ atEnvMonv2PsbSensorBoardIndex ■ atEnvMonv2PsbSensorIndex ■ atEnvMonv2PsbSensorType ■ atEnvMonv2PsbSensorDescription
atEnvMonv2PsbAlarmClearedNotify { atEnvMonv2Notifications 8 }	Notification generated when a monitored parameter of a power supply bay device returns to an acceptable value, having previously been in an alarm condition. It returns the value of: ■ atEnvMonv2PsbSensorStackMemberId ■ atEnvMonv2PsbSensorBoardIndex ■ atEnvMonv2PsbSensorIndex ■ atEnvMonv2PsbSensorType ■ atEnvMonv2PsbSensorDescription
atEnvMonv2FanTable { EnvMonv2 1 }	Table of information about fans installed in the device that have their fan speeds monitored by environment monitoring hardware, indexed by: ■ atEnvMonv2FanStackMemberId ■ atEnvMonv2FanBoardIndex ■ atEnvMonv2FanIndex
atEnvMonv2FanEntry { atEnvMonv2FanTable 1 }	Description, current speed, lower threshold speed and current status of a single fan.
atEnvMonv2FanStackMemberId { atEnvMonv2FanEntry 1 }	Index of the stack member hosting this fan.
atEnvMonv2FanBoardIndex { atEnvMonv2FanEntry 2 }	Index of the board hosting this fan in the board table.
atEnvMonv2FanIndex { atEnvMonv2FanEntry 3 }	Numeric identifier of this fan on its host board.
atEnvMonv2FanDescription { atEnvMonv2FanEntry 4 }	Description of this fan.
atEnvMonv2FanCurrentSpeed { atEnvMonv2FanEntry 5 }	Current speed of this fan in revolutions per minute.

Table 89-9: Objects defined in AT-ENVMONV2-MIB(cont.)

Object / Object Identifier	Description
atEnvMonv2FanLowerThreshold { atEnvMonv2FanEntry 6 }	Minimum acceptable speed of the fan in revolutions per minute.
atEnvMonv2FanStatus { atEnvMonv2FanEntry 7 }	Whether this fan is currently in an alarm condition. The values can be: ■ Failed (1) means that the current speed is too low. ■ Good (2) means that the current speed is acceptable.
atEnvMonv2VoltageTable { atEnvMonv2 2 }	Table of information about voltage rails in the device that are monitored by environment monitoring hardware, indexed by: ■ atEnvMonv2VoltageStackMemberId ■ atEnvMonv2VoltageBoardIndex ■ atEnvMonv2VoltageIndex
atEnvMonv2VoltageEntry { atEnvMonv2VoltageTable 1 }	Description, current value, upper & lower threshold settings and current status of a single voltage rail.
atEnvMonv2VoltageStackMemberId { atEnvMonv2VoltageEntry 1 }	Index of the stack member hosting this voltage sensor.
atEnvMonv2VoltageBoardIndex { atEnvMonv2VoltageEntry 2 }	Index of the board hosting this voltage sensor in the board table.
atEnvMonv2VoltageIndex { atEnvMonv2VoltageEntry 3 }	Numeric identifier of this voltage rail on its host board.
atEnvMonv2VoltageDescription { atEnvMonv2VoltageEntry 4 }	Description of this voltage rail.
atEnvMonv2VoltageCurrent { atEnvMonv2VoltageEntry 5 }	Current reading of this voltage rail in millivolts.
atEnvMonv2VoltageUpperThreshold { atEnvMonv2VoltageEntry 6 }	Maximum acceptable reading of this voltage rail in millivolts.
atEnvMonv2VoltageLowerThreshold { atEnvMonv2VoltageEntry 7 }	Minimum acceptable reading of this voltage rail in millivolts.
atEnvMonv2VoltageStatus { atEnvMonv2VoltageEntry 8 }	Whether this voltage rail is currently in an alarm condition. Possible values are: ■ outOfRange (1) - means that the current reading is outside the threshold range. ■ inRange (2) - means that the current reading is acceptable.
atEnvMonv2TemperatureTable { atEnvMonv2 3 }	Table of information about temperature sensors in the device that are monitored by environment monitoring hardware, indexed by: ■ atEnvMonv2TemperatureStackMemberId ■ atEnvMonv2TemperatureBoardIndex ■ atEnvMonv2TemperatureIndex
atEnvMonv2TemperatureEntry { atEnvMonv2TemperatureTable 1 }	Description, current value, upper threshold setting and current status of a single temperature sensor.
atEnvMonv2TemperatureStackMemberId { atEnvMonv2TemperatureEntry 1 }	Index of the stack member hosting this temperature sensor.
atEnvMonv2TemperatureBoardIndex { atEnvMonv2TemperatureEntry 2 }	Index of the board hosting this temperature sensor in the board table.
atEnvMonv2TemperatureIndex { atEnvMonv2TemperatureEntry 3 }	Numeric identifier of this temperature sensor on its host board.
atEnvMonv2TemperatureDescription { atEnvMonv2TemperatureEntry 4 }	Description of this temperature sensor.
atEnvMonv2TemperatureCurrent { atEnvMonv2TemperatureEntry 5 }	Current reading of this temperature sensor in degrees Celsius.

Table 89-9: Objects defined in AT-ENVMONV2-MIB(cont.)

Object / Object Identifier	Description
atEnvMonv2TemperatureUpperThreshold { atEnvMonv2TemperatureEntry 6 }	Maximum acceptable reading for this temperature sensor in degrees Celsius.
atEnvMonv2TemperatureStatus { atEnvMonv2TemperatureEntry 7 }	Whether this temperature sensor is currently in an alarm condition. Can be: ■ outOfRange (1) - means that the current reading is outside the threshold range. ■ inRange (2) - means that the current reading is acceptable.
atEnvMonv2PsbObjects { atEnvMonv2 4 }	Collection of objects for monitoring power supply bays in the system and any devices that are installed. It contains the following objects: ■ atEnvMonv2PsbTable ■ atEnvMonv2PsbSensorTable
atEnvMonv2PsbTable { atEnvMonv2PsbObjects 1 }	Table of information about power supply bays in the system, indexed by: ■ atEnvMonv2PsbHostStackMemberId ■ atEnvMonv2PsbHostBoardIndex ■ atEnvMonv2PsbHostSlotIndex
atEnvMonv2PsbEntry { atEnvMonv2PsbTable 1 }	Description and current status of a single power supply bay device.
atEnvMonv2PsbHostStackMemberId { atEnvMonv2PsbEntry 1 }	Index of the stack member hosting this power supply bay.
atEnvMonv2PsbHostBoardIndex { atEnvMonv2PsbEntry 2 }	Index of the board hosting this power supply bay in the board table.
atEnvMonv2PsbHostSlotIndex { atEnvMonv2PsbEntry 3 }	Index of this power supply bay slot on its host board. This index is fixed for each slot, on each type of board.
atEnvMonv2PsbHeldBoardIndex { atEnvMonv2PsbEntry 4 }	Index of a board installed in this power supply bay. This value corresponds to atEnvMonv2PsbSensorBoardIndex for each sensor on this board. A value of 0 indicates that a board is either not present or not supported.
atEnvMonv2PsbHeldBoardId { atEnvMonv2PsbEntry 5 }	Type of board installed in this power supply bay. The values of this object are taken from the pprXxx object IDs under the boards sub-tree in the parent MIB. A value of 0 indicates that a board is either not present or not supported.
atEnvMonv2PsbDescription { atEnvMonv2PsbEntry 6 }	Description of this power supply bay.
atEnvMonv2PsbSensorTable { atEnvMonv2PsbObjects 2 }	Table of information about environment monitoring sensors on devices installed in power supply bays, indexed by: ■ atEnvMonv2PsbSensorStackMemberId ■ atEnvMonv2PsbSensorBoardIndex ■ atEnvMonv2PsbSensorIndex
atEnvMonv2PsbSensorEntry { atEnvMonv2PsbSensorTable 1 }	Description and current status of the sensor on a device installed in a power supply bay.
atEnvMonv2PsbSensorStackMemberId { atEnvMonv2PsbSensorEntry 1 }	Index of the stack member hosting this sensor.
atEnvMonv2PsbSensorBoardIndex { atEnvMonv2PsbSensorEntry 2 }	Index of the board hosting this sensor in the board table.
atEnvMonv2PsbSensorIndex { atEnvMonv2PsbSensorEntry 3 }	Index of this power supply bay environmental sensor on its host board.

Table 89-9: Objects defined in AT-ENVMONV2-MIB(cont.)

Object / Object Identifier	Description
atEnvMonv2PsbSensorType { atEnvMonv2PsbSensorEntry 4 }	Type of environmental variable this sensor detects. One of: ■ psbSensorTypeInvalid(0) ■ fanSpeedDiscrete(1) ■ temperatureDiscrete(2) ■ voltageDiscrete(3)
atEnvMonv2PsbSensorDescription { atEnvMonv2PsbSensorEntry 5 }	Description of this power supply bay environmental sensor.
atEnvMonv2PsbSensorStatus { atEnvMonv2PsbSensorEntry 6 }	Whether this environmental sensor is currently in an alarm condition. One of: ■ failed (1) - means that the device is in a failure condition ■ good(2) - means that the device is functioning normally. ■ notPowered (3) - a PSU is installed, but not powered up
atEnvMonv2FaultLedTable { atEnvMonv2 6 }	Table detailing any LED fault indications on the device, indexed by: ■ atEnvMonv2FaultLedStackMemberId
atEnvMonv2FaultLedEntry { atEnvMonv2FaultLedTable 1 }	Information pertaining to a given fault LED.
atEnvMonv2FaultLedStackMemberId { atEnvMonv2FaultLedEntry 1 }	Index of the stack member hosting this fault LED.
atEnvMonv2FaultLed1Flash { atEnvMonv2FaultLedEntry 2 }	Indicates whether a fault LED is currently showing a system failure by flashing once. Values can be: ■ heatsinkFanFailure (1) - indicates that one or more heatsink fans have failed, or are operating below the recommended speed ■ noFault (2)
atEnvMonv2FaultLed2Flashes { atEnvMonv2FaultLedEntry 3 }	Indicates whether a fault LED is currently showing a system failure by flashing twice. Values can be: ■ chassisFanFailure (1) - indicates that one or both of the chassis fans are not installed, or the fans are operating below the recommended speed ■ noFault (2)
atEnvMonv2FaultLed3Flashes { atEnvMonv2FaultLedEntry 4 }	Indicates whether a fault LED is currently showing a system failure by flashing three times. Values can be: ■ sensorFailure (1) - indicates that the ability to monitor temperature or fans has failed ■ noFault (2)
atEnvMonv2FaultLed4Flashes { atEnvMonv2FaultLedEntry 5 }	Indicates whether a fault LED is currently showing a system failure by flashing four times. Values can be: ■ xemInitialisationFailure (1) - indicates that a XEM failed to initialise or is incompatible ■ noFault (2)
atEnvMonv2FaultLed5Flashes { atEnvMonv2FaultLedEntry 6 }	Indicates whether a fault LED is currently showing a system failure by flashing five times. This flashing sequence is not currently in use. Value is: ■ noFault (2)
atEnvMonv2FaultLed6Flashes { atEnvMonv2FaultLedEntry 7 }	Indicates whether a fault LED is currently showing a system failure by flashing six times. Values can be: ■ temperatureFailure (1) - indicates that the device's temperature has exceeded the recommended threshold ■ noFault (2)

AT-VCSTACK-MIB

AT-VCSTACK-MIB defines objects for managing Virtual Chassis Stacking (Table 89-10). Objects in this group have the object identifier vcstack ({ sysinfo 13 }).

Figure 89-2 on page 89.22 shows the tree structure of the AT-VCSTACK objects.

Figure 89-2: The AT-VCSTACK MIB sub-tree

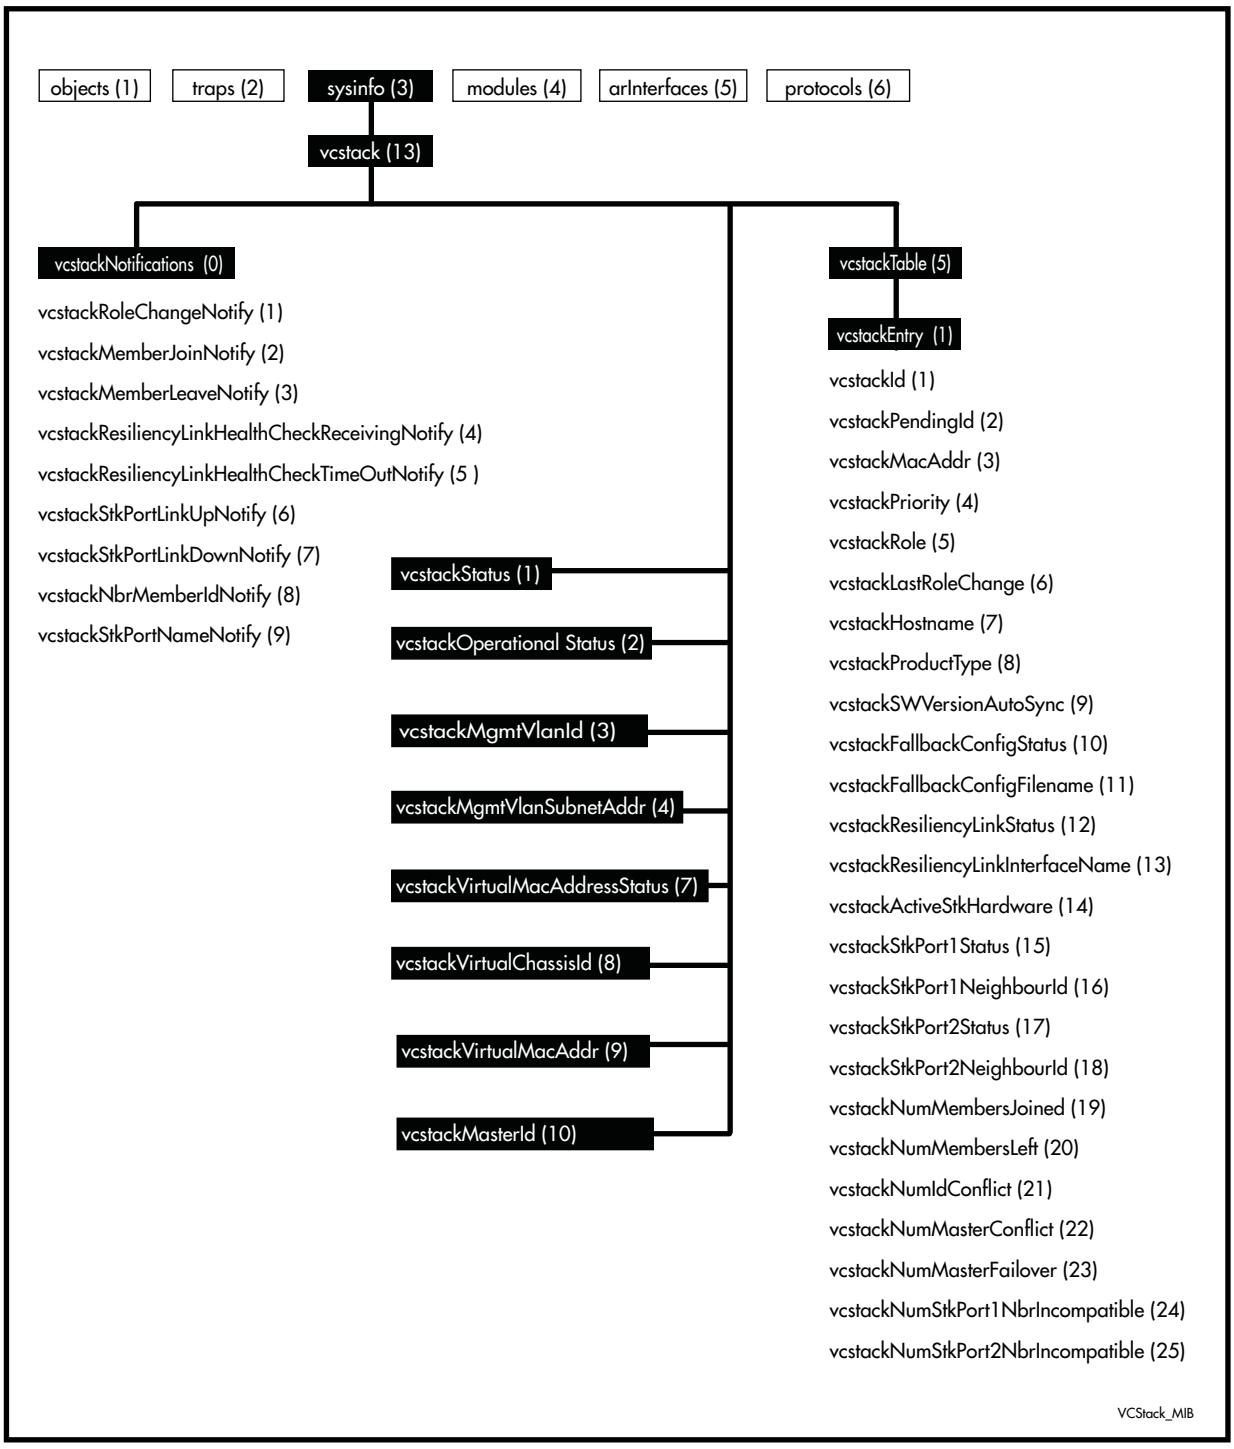


Table 89-10: Objects defined in AT-VCSTACK-MIB

Object	Object Identifier	Description
vcstack	{ sysinfo (13) }	Overall stack status.
vcstackNotifications	{ vcstack 0 }	List of traps (notifications) generated for the stack:
vcstackRoleChangeNotify	{ vcstackNotifications 1 }	The stack status can take one of the following states: ■ normalOperation (1) ■ operatingInFailoverState (2) ■ standaloneUnit (3) ■ ringTopologyBroken (4)
vcstackMemberJoinNotify	{ vcstackNotifications 2 }	Notification generated when a member joins the stack. Displays the objects: ■ vcstackId ■ vcstackNbrMemberId
vcstackMemberLeaveNotify	{ vcstackNotifications 3 }	Notification generated when a member leaves the stack. Displays the objects: ■ vcstackId ■ vcstackNbrMemberId
vcstackResiliencyLinkHealthCheckReceivingNotify	{ vcstackNotifications 4 }	Notification generated when the resiliency link is activated. Displays the objects: ■ vcstackId ■ vcstackResiliencyLinkInterface Name
vcstackResiliencyLinkHealthCheckTimeOutNotify	{ vcstackNotifications 5 }	Notification generated when the slave's receive timer has timed-out, indicating that the Slave has lost contact with the Master via the resiliency link. Displays the objects: ■ vcstackId ■ vcstackResiliencyLinkInterface Name
vcstackStkPortLinkUpNotify	{ vcstackNotifications 6 }	Notification generated when the stack port link is up. Displays the objects: ■ vcstackId ■ vcstackStkPortName
vcstackStkPortLinkDownNotify	{ vcstackNotifications 7 }	Notification generated when the stack port link is down. Displays the objects: ■ vcstackId ■ vcstackStkPortName
vvcstackNbrMemberIdNotify	{ vcstackNotifications 8 }	The stack member id related to this trap
vcstackStkPortNameNotify	{ vcstackNotifications 9 }	The stack port name related to this trap

Table 89-10: Objects defined in AT-VCSTACK-MIB(cont.)

Object	Object Identifier	Description
vcstackOperationalStatus	{ vcstack 2 }	The operational status of the stack can be either: ■ enabled (1) ■ disabled (2)
vcstackMgmtVlanId	{ vcstack 3 }	The current stacking management VLAN ID
vcstackMgmtVlanSubnetAddr	{ vcstack 4 }	The current stacking management VLAN subnet address
vcstackTable	{ vcstack 5 }	Table of information about stack members, indexed by vcstackId.
vcstackEntry	{ vcstackTable 1 }	Information about a single stack member, indexed by vcstackId.
vcstackId	{ vcstackEntry 1 }	Stack member ID.
vcstackPendingId	{ vcstackEntry 2 }	Pending stack member ID.
vcstackMacAddr	{ vcstackEntry 3 }	Stack member's hardware MAC address.
vcstackPriority	{ vcstackEntry 4 }	Priority for election of the stack master. The lowest number has the highest priority.
vcstackRole	{ vcstackEntry 5 }	Stack member's role in the stack. Can be one of the following: ■ leaving (1) ■ discovering (2) ■ synchronizing (3) ■ backupMember (4) ■ pendingMaster (5) ■ disabledMaster (6) ■ fallbackMaster (7) ■ activeMaster (8)
vcstackLastRoleChange	{ vcstackEntry 6 }	Time and date when the stack member last changed its role in the stack.
vcstackHostname	{ vcstackEntry 7 }	Stack member's hostname.
vcstackProductType	{ vcstackEntry 8 }	Stack members product type.
vcstackSWVersionAutoSync	{ vcstackEntry 9 }	Whether or not the stack member's software is automatically upgraded.
vcstackFallbackConfigStatus	{ vcstackEntry 10 }	Status of the fallback configuration file. Can be one of: ■ fileExists (1) ■ fileNotFound (2) ■ notConfigured (3)

Table 89-10: Objects defined in AT-VCSTACK-MIB(cont.)

Object	Object Identifier	Description
vcstackFallbackConfigFilename	{ vcstackEntry 11 }	Filename of the fallback configuration file.
vcstackResiliencyLinkStatus	{ vcstackEntry 12 }	Status of the stack members resiliency link. Can be one of: ■ configured (1) ■ successful (2) ■ failed (3) ■ notConfigured (4)
vcstackResiliencyLinkInterfaceName	{ vcstackEntry 13 }	Name of the interface the resiliency link is configured on.
vcstackActiveStkHardware	{ vcstackEntry 14 }	Stack ports hardware type. Can be one of: ■ value (0) is now obsolete ■ xemStk (1) ■ builtinStackingPorts (2) ■ none (3) is now obsolete ■ stackXG (4)
vcstackStkPort1Status	{ vcstackEntry 15 }	Status of stack-port 1. Can be one of the following: ■ down (1) ■ neighbourIncompatible (2) ■ discoveringNeighbour (3) ■ learntNeighbour (4)
vcstackStkPort1NeighbourId	{ vcstackEntry 16 }	ID of the neighbor on stack-port 1. Zero indicates no learned neighbor.
vcstackStkPort2Status	{ vcstackEntry 17 }	Status of stack-port 2. Can be one of: ■ down (1) ■ neighbourIncompatible (2) ■ discoveringNeighbour (3) ■ learntNeighbour (4)
vcstackStkPort2NeighbourId	{ vcstackEntry 18 }	ID of the neighbor on stack-port 2. Zero indicates no learned neighbor.
vcstackNumMembersJoined	{ vcstackEntry 19 }	Number of times the stack has acquired a member.
vcstackNumMembersLeft	{ vcstackEntry 20 }	Number of times the stack has lost a member.
vcstackNumIdConflict	{ vcstackEntry 21 }	Number of times that a stack member ID conflict has occurred.
vcstackNumMasterConflict	{ vcstackEntry 22 }	Number of times that a stack master conflict has occurred.
vcstackNumMasterFailover	{ vcstackEntry 23 }	Number of times that the stack master has failed.

Table 89-10: Objects defined in AT-VCSTACK-MIB(cont.)

Object	Object Identifier	Description
vcstackNumStkPort1NbrIncompatible	{ vcstackEntry 24 }	Number of times that the neighbor on stack port 1 was incompatible.
vcstackNumStkPort2NbrIncompatible	{ vcstackEntry 25 }	Number of times that the neighbor on stack port 2 was incompatible.
vcstackVirtualMacAddressStatus	{vcstack 7}	Indicates whether the virtual MAC address is enabled or disabled. Read-only object.
vcstackVirtualChassisId	{vcstack 8}	Displays the current virtual chassis ID. Read-only object.
vcstackVirtualMacAddr	{vcstack 9}	Displays the virtual MAC address used by the stack. Read-only object.
vcstackMasterId	{vcstack 10}	Displays the stack ID of the master unit, or the stack ID of the standalone unit. Read-only object

AT-MIBVERSION-MIB

The AT-MIBVERSION-MIB contains an object to display the last software release that contained changes to the supported AT Enterprise MIB definition files (Table 89-11). Objects in this group have the object identifier atMibsetVersion ({ sysinfo 15 }).

Table 89-11: Object defined in AT-MIBVERSION-MIB

Object	Object Identifier	Description
atMibsetVersion	{ sysinfo 15 }	This object returns a five digit integer which indicates the last software release that contained changes to the supported AT Enterprise MIB definition files. For example, If the currently loaded software release on the device is 5.3.1-0.3 but the Enterprise MIBs have not changed since 5.3.1-0.1, then the value returned will be 53101.

AT-USER-MIB

The AT-USER-MIB contains objects for displaying information about users currently logged into a device, or configured in the Local User Database of the device (Table 89-12). Objects in this group have the object identifier user ({ sysinfo 20 }).

Table 89-12: Objects defined in AT-USER-MIB

Object	Object Identifier	Description
userInfoTable	{ user 1 }	Table containing information about users. Each entry in the table represents a user currently logged into the device. Indexed by: rscBoardType and rscBoardIndex.
userInfoEntry	{ userInfoTable 1 }	Information about a single user logged into the device.
userInfoType	{ userInfoEntry 1 }	The type of connection through which the user logged into the device. Can be: ■ console (1) ■ aux (2) ■ telnet (3) ■ script (4) ■ stack (5)
userInfoIndex	{ userInfoEntry 2 }	Index of the line upon which the user logged into the device. Can be a value in range 1 to 16.
userInfoName	{ userInfoEntry 3 }	User name of the user logged into the device.
userInfoPrivilegeLevel	{ userInfoEntry 4 }	The user's privilege level. Can be a value in range 1 to 15.
userInfoIdleTime	{ userInfoEntry 5 }	The amount of time since the user was last active, in the form hh:mm:ss.
userInfoLocation	{ userInfoEntry 6 }	The user location or login method. It can be an IP Address used by the user to telnet into the device, or an asyn port, etc.
userInfoPasswordLifetime	{ userInfoEntry 7 }	The number of days remaining until the user's password expires. Depending on the current user setting it will display one of the following: ■ No Expiry - the password will never expire (default setting) ■ x days - where x is the remaining lifetime of the current password (maximum lifetime value is 1000 days) ■ -x days (expired) - indicating that the current password expired x days ago
userInfoPasswordLastChange	{ userInfoEntry 8 }	The number of days since the password was last altered.

Table 89-12: Objects defined in AT-USER-MIB(cont.)

Object	Object Identifier	Description
userConfigTable	{ user 2 }	Table containing user configuration information. Each entry in the table relates to a user configured in the Local User Database of the device. Indexed by userConfigIndex.
userConfigEntry	{ userConfigTable 1 }	Information about a single user configured in the Local User Database of the device.
userConfigIndex	{ userConfigEntry 1 }	Unique number used to identify entries in the userConfigTable.
userConfigName	{ userConfigEntry 2 }	The user's name.
userConfigPrivilegeLevel	{ userConfigEntry 3 }	The privilege level granted to the user. Can be a value in range 1 to 15.
userSecurityPasswordRules	{ user 3 }	Information about user password security rules.
userSecurityPasswordHistory	{ userSecurityPasswordRules 1 }	The number of previous passwords that are retained for comparison when a user password is created. A new password must be unique when compared against the previous history. A value of 0 represents no restriction. The maximum number of retained passwords is 15.
userSecurityPasswordLifetime	{ userSecurityPasswordRules 2 }	The maximum number of days that the password may persist before a change is required. A value of 0 represents no expiry. The maximum value is 1000.
userSecurityPasswordWarning	{ userSecurityPasswordRules 3 }	The number of days before the password expires that a warning message is displayed when the user logs in. A value of 0 indicates no warning. The maximum value is 1000 but must always be less than the password lifetime.
userSecurityPasswordMinLength	{ userSecurityPasswordRules 4 }	The minimum allowable password length.
userSecurityPasswordMinCategory	{ userSecurityPasswordRules 5 }	The minimum number of different categories that the password must satisfy to be considered valid. Categories are split into four groups: ■ upper-case letters ■ lower-case letters ■ digits ■ special symbols. ASCII characters not included in the previous three categories.
userSecurityPasswordForced	{ userSecurityPasswordRules 6 }	Whether or not a user with an expired password is forced to change their password at the next login. At login a user with an expired password is prompted to change their password. If the new password meets the current security password rules the user is allowed to login, otherwise they are rejected.
userSecurityPasswordReject	{ userSecurityPasswordRules 7 }	Whether or not a user login attempt with an expired password is rejected. If the user is not rejected then they can login.

AT-RESOURCE-MIB

The AT-RESOURCE-MIB contains objects for displaying system hardware resource and host information (Table 89-13). Objects in this group have the object identifier rsc ({ sysinfo 21 }).

Table 89-13: Objects defined in AT-RESOURCE-MIB

Object	Object Identifier	Description
resource	{ sysinfo 21 }	Contains objects for displaying system hardware resource and host information.
rscBoardTable	{ resource 1 }	Table containing information about boards installed in a device. Indexed by: ■ rscStkId ■ rscResourceId
rscBoardEntry	{ rscBoardTable 1 }	Information about a single board installed in the device.
rscStkId	{ rscBoardEntry 1 }	The ID of the stack member. It is a number from 1 to 8, assigned to a stackable unit by the operating system when it is stacked. A default of 1 is given to a stand-alone unit.
rscResourceId	{ rscBoardEntry 2 }	The resource ID number of the board. It is a number assigned to a hardware resource when the operating system detects its existence. Can be a value in range 1 to 4294967294.
rscBoardType	{ rscBoardEntry 3 }	The type of board. Can be one of the following: ■ Base ■ Expansion ■ Fan module ■ PSU, etc.
rscBoardName	{ rscBoardEntry 4 }	The name of the board. Can be one of the following: ■ SwitchBlade x908 ■ XEM-12S ■ AT-PWR05-AC, etc
rscBoardId	{ rscBoardEntry 5 }	The ID number of the board. Its value is an Allied Telesis assigned number, such as 274 for the XEM-12S, or 255 for the AT-9924Ts.
rscBoardBay	{ rscBoardEntry 6 }	The board installation location. Its value can be Bay1, Bay2, PSU1, etc. For a base board, it has a value of a single character space.
rscBoardRevision	{ rscBoardEntry 7 }	The revision number of the board.
rscBoardSerialNumber	{ rscBoardEntry 8 }	The serial number of the board.
hostInfoTable	{ resource 2 }	Table containing general system information. Indexed by rscStkId.
hostInfoEntry	{ hostInfoTable 1 }	Information about a single system parameter
hostInfoDRAM	{ hostInfoEntry 1 }	The host DRAM information.
hostInfoFlash	{ hostInfoEntry 2 }	The host Flash information.
hostInfoUptime	{ hostInfoEntry 3 }	The host up-time.
hostInfoBootloaderVersion	{ hostInfoEntry 4 }	The host boot loader version.

AT-LICENSE-MIB

The AT-LICENSE-MIB contains objects for managing the AlliedWare Plus™ Operating System software licenses: listing applied software licenses, adding new licenses and deleting existing licenses (Table 89-14). The objects reside in the module license { sysinfo 22 }, organized in the following groups:

- Base Software License Table - a table containing the installed base software licenses on the device
- Installed Software License Table - a list of installed software licenses; used also to remove software license from the device
- Available Software Features Table
- LicenseNew - Objects used to install a new license
- LicenseStackRemove - Objects used to remove a license across a stack of devices

Table 89-14: Objects defined in AT-LICENSE-MIB

Object	Object Identifier	Description
license	{ sysinfo 22 }	MIB containing objects for listing applied software licenses, adding new licenses, and deleting existing licenses.
baseLicenseTable	{ license 1 }	Table containing information about base software licenses installed on a device. Indexed by: ■ baseLicenseStkId
baseLicenseEntry	{ baseLicenseTable 1 }	Information about a single license installed on the device.
baseLicenseStkId	{ baseLicenseEntry 1 }	The stack member ID of the device hosting the license.
baseLicenseName	{ baseLicenseEntry 2 }	The name of the base license.
baseLicenseQuantity	{ baseLicenseEntry 3 }	The number of licenses issued for this entry.
baseLicenseType	{ baseLicenseEntry 4 }	The type of base license issued.
baseLicenseIssueDate	{ baseLicenseEntry 5 }	The date of issue of the base license.
baseLicenseExpiryDate	{ baseLicenseEntry 6 }	The expiry date of the base license.
baseLicenseFeatures	{ baseLicenseEntry 7 }	The feature set that this license enables, in the format of an octet string. Each bit in the returned octet string represents a particular feature that can be license-enabled. The bit position within the string maps to the feature entry with the same index, in licenseFeatureTable. A binary '1' indicates that the feature is included in the license; a binary '0' indicates that the feature is not included in the license.
licenseTable	{ license 2 }	Table containing information about software licenses installed on the device. Indexed by: ■ licenseStackId ■ licenseIndex
licenseEntry	{ licenseTable 1 }	Information about a single installed software license on the device.
llicenseStackId	{ licenseEntry 1 }	The stack member ID of the device hosting the license.
licenseIndex	{ licenseEntry 2 }	The index number of the license entry.
licenseName	{ licenseEntry 3 }	The name of the license.
licenseCustomer	{ licenseEntry 4 }	The name of the customer of the license.
licenseQuantity	{ licenseEntry 5 }	The number of licenses issued for this entry.
licenseType	{ licenseEntry 6 }	The type of license issued.
licenseIssueDate	{ licenseEntry 7 }	The date of issue of the license.

Table 89-14: Objects defined in AT-LICENSE-MIB(cont.)

Object	Object Identifier	Description
licenseExpiryDate	{ licenseEntry 8 }	The expiry date of the license.
licenseFeatures	{ licenseEntry 9 }	The feature set that this license enables, in the format of octet string. Each bit in the returned octet string represents a particular feature that can be license-enabled. The bit position within the string maps to the feature entry with the same index, in licenseFeatureTable. A binary '1' indicates that the feature is included in the license; a binary '0' indicates that the feature is not included in the license.
licenseRowStatus	{ licenseEntry 10 }	The current status of the license. The following values may be returned when reading this object: ■ active (1) - the license is currently installed and valid ■ notInService (2) - the license has expired or is invalid The following value may be written to this object: ■ destroy (6) - the license will be removed from the device; this may result in some features being disabled. Note that a stacked device that has a license deleted may not be able to rejoin the stack after reboot, unless the license is also deleted on all other devices in the stack.
licenseFeatureTable	{ license 3 }	Table containing all available Software Features. A feature must be license-enabled to be utilized on the device.
licenseFeatureEntry	{ licenseFeatureTable 1 }	Information about a single feature that must be license-enabled in order to be utilized on the device.
licenseFeatureIndex	{ licenseFeatureEntry 1 }	The index number of the feature which must be license-enabled.
licenseFeatureName	{ licenseFeatureEntry 2 }	The name of the feature under licensing control.
licenseFeatureStkMembers	{ licenseFeatureEntry 3 }	The set of stack members on which the feature is enabled, in the format of an octet string. Each bit in the string maps to an individual stacking member, e.g. bit one represents stacking member one, bit two represents stacking member two, etc. A bit value of '1' indicates that the applicable feature is enabled on the matching device; a bit value of '0' indicates that the feature is disabled.
licenseNew	{ license 4 }	Group of objects available for updates, used when installing a new software license on the device.
licenseNewStackId	{ licenseNew 1 }	The ID of the stacking member upon which the new license is to be installed. The value zero (0) indicates that the license should be applied to all stack members.
licenseNewName	{ licenseNew 2 }	The name of the new license to be installed.
licenseNewKey	{ licenseNew 3 }	The key for the new license to be installed.

Table 89-14: Objects defined in AT-LICENSE-MIB(cont.)

Object	Object Identifier	Description
licenseNewInstall	{ licenseNew 4 }	Used to install new licenses. Values can be: ■ true (1) ■ false (2) To commence installation, a valid license name and key must first have been set via the licenseNewName and licenseNewKey respectively. This object should then be set to the value true (1). If either the license name or key is invalid, the write operation will fail. Once installed, the software modules affected by any newly enabled features will automatically be restarted. Note that a stacked device that has a new license installed on it may not be able to rejoin the stack after reboot, unless the license is also added to all other devices in the stack. When read, the object will always return the value false (2).
licenseNewInstallStatus	{ licenseNew 5 }	The current status of the last license installation request. One of the following values is returned when reading this object: ■ idle (1) ■ processing (2) ■ success (3) ■ failed (4) When a stack license installation operation is complete the first read of this object will return either a success (3) or a failure (4) indication. Subsequent reads of this object will then return an idle (1) indication.
licenseStackRemove	{ license 5 }	Group of objects used when removing a software license across a stack of devices.
licenseStackRemoveName	{ licenseStackRemove 1 }	The name of the license to be removed from all devices across the stack, on which the license currently exists.
licenseStackRemoveExecute	{ licenseStackRemove 2 }	When set to the value true (1), the system will attempt to remove the named license from all devices across the stack on which the license currently exists. All devices in a stack must be from the same product family and the named license must activate the same feature set on all devices.
licenseStackRemoveStatus	{ licenseStackRemove 3 }	The current status of the last requested stack license removal request. One of the following values is returned when reading this object: ■ idle (1) ■ processing (2) ■ success (3) ■ failed (4) When a stack license removal operation is complete the first read of this object will return either a success (3) or failure (4) indication. Subsequent reads of this object will then return an idle (1) indication.

AT-TRIGGER-MIB

AT-TRIGGER-MIB defines objects for managing triggers (Table 89-15). Objects in this group have the object identifier trigger ({ modules 53 }). All objects in this group have read only access.

Table 89-15: Objects defined in AT-TRIGGER-MIB

Object Identifier	Description
triggerTraps { trigger 0 }	Sub-tree for all trigger traps.
triggerTrap { triggerTraps 1 }	Notification generated when a trigger is activated. It returns the value of triggerLastTriggerActivated.
triggerLastTriggerActivated { trigger 1 }	Trigger number of the most recent trigger activated on the switch.
triggerConfigInfoTable { trigger 9 }	Table of information about each trigger that has been configured, indexed by triggerNumber.
triggerConfigInfoEntry { triggerConfigInfoTable 1 }	Information about the configuration of a single trigger.
triggerNumber { triggerConfigInfoEntry 1 }	ID number of the trigger. Values are in range 1- 250.
triggerName { triggerConfigInfoEntry 2 }	Name and description of the trigger.
triggerTypeDetail { triggerConfigInfoEntry 3 }	Trigger type and its activation conditions.
triggerActiveDaysOrDate { triggerConfigInfoEntry 4 }	The days of a week or the date on which the trigger can be activated.
triggerActivateAfter { triggerConfigInfoEntry 5 }	Time after which the trigger can be activated.
triggerActivateBefore { triggerConfigInfoEntry 6 }	Time before which the trigger can be activated.
triggerActiveStatus { triggerConfigInfoEntry 7 }	Whether or not the trigger can be activated.
triggerTestMode { triggerConfigInfoEntry 8 }	Whether or not the trigger is operating in diagnostic (test) mode.
triggerSnmpTrap { triggerConfigInfoEntry 9 }	Whether or a not an SNMP trap will be generated when the trigger is activated.
triggerRepeatTimes { triggerConfigInfoEntry 10 }	Whether the trigger can repeat an unlimited number of times (continuous) or a specified number of times. If the trigger can repeat only a specified number of times, then the number of times the trigger has already been activated is displayed in brackets.
triggerLasttimeModified { triggerConfigInfoEntry 11 }	Date and time that the trigger configuration was last modified.
triggerNumberOfActivation { triggerConfigInfoEntry 12 }	Number of times the trigger has been activated since the last restart of the device.
triggerLasttimeActivation { triggerConfigInfoEntry 13 }	Date and time that the trigger was last activated.
triggerNumberOfScripts { triggerConfigInfoEntry 14 }	Number of scripts that this trigger will execute. Values are in range 0-5.

Table 89-15: Objects defined in AT-TRIGGER-MIB(cont.)

Object Identifier	Description
triggerScript1 { triggerConfigInfoEntry 15 }	Name of the first script that this trigger will execute if the trigger is activated.
triggerScript2 { triggerConfigInfoEntry 16 }	Name of the second script that this trigger will execute if the trigger is activated.
triggerScript3 { triggerConfigInfoEntry 17 }	Name of the third script that this trigger will execute if the trigger is activated.
triggerScript4 { triggerConfigInfoEntry 18 }	Name of the fourth script that this trigger will execute if the trigger is activated.
triggerScript5 { triggerConfigInfoEntry 19 }	Name of the fifth script that this trigger will execute if the trigger is activated.
triggerCounters { trigger 10 }	Collection of counters for trigger activations.
triggerNumOfActivation { triggerCounters 1 }	Number of times a trigger has been activated.
triggerNumOfActivationToday { triggerCounters 2 }	Number of times a trigger has been activated today.
triggerNumOfPerodicActivationToday { triggerCounters 3 }	Number of times a periodic trigger has been activated today.
triggerNumOfInterfaceActivationToday { triggerCounters 4 }	Number of times an interface trigger has been activated today.
triggerNumOfResourceActivationToday { triggerCounters 5 }	Number of times a CPU or memory trigger has been activated today.
triggerNumOfRebootActivationToday { triggerCounters 6 }	Number of times a reboot trigger has been activated today.
triggerNumOfPingPollActivationToday { triggerCounters 7 }	Number of times a ping-poll trigger has been activated today.
triggerNumOfStackMasterFailActivationToday { triggerCounters 8 }	Number of times a stack master fail trigger has been activated today.
triggerNumOfStackMemberActivationToday { triggerCounters 9 }	Number of times a stack member trigger has been activated today.
triggerNumOfStackXemStkActivationToday { triggerCounters 10 }	Number of times a stack XEM trigger has been activated today.

AT-LOOPPROTECT-MIB

The atLoopProtect-MIB (Figure 89-3, Table 89-16) defines objects for managing Loop Protection objects and triggers. Objects in this group have the object identifier atLoopProtect ({ modules 4 }).

Figure 89-3: The ATLoopProtect MIB Sub-tree

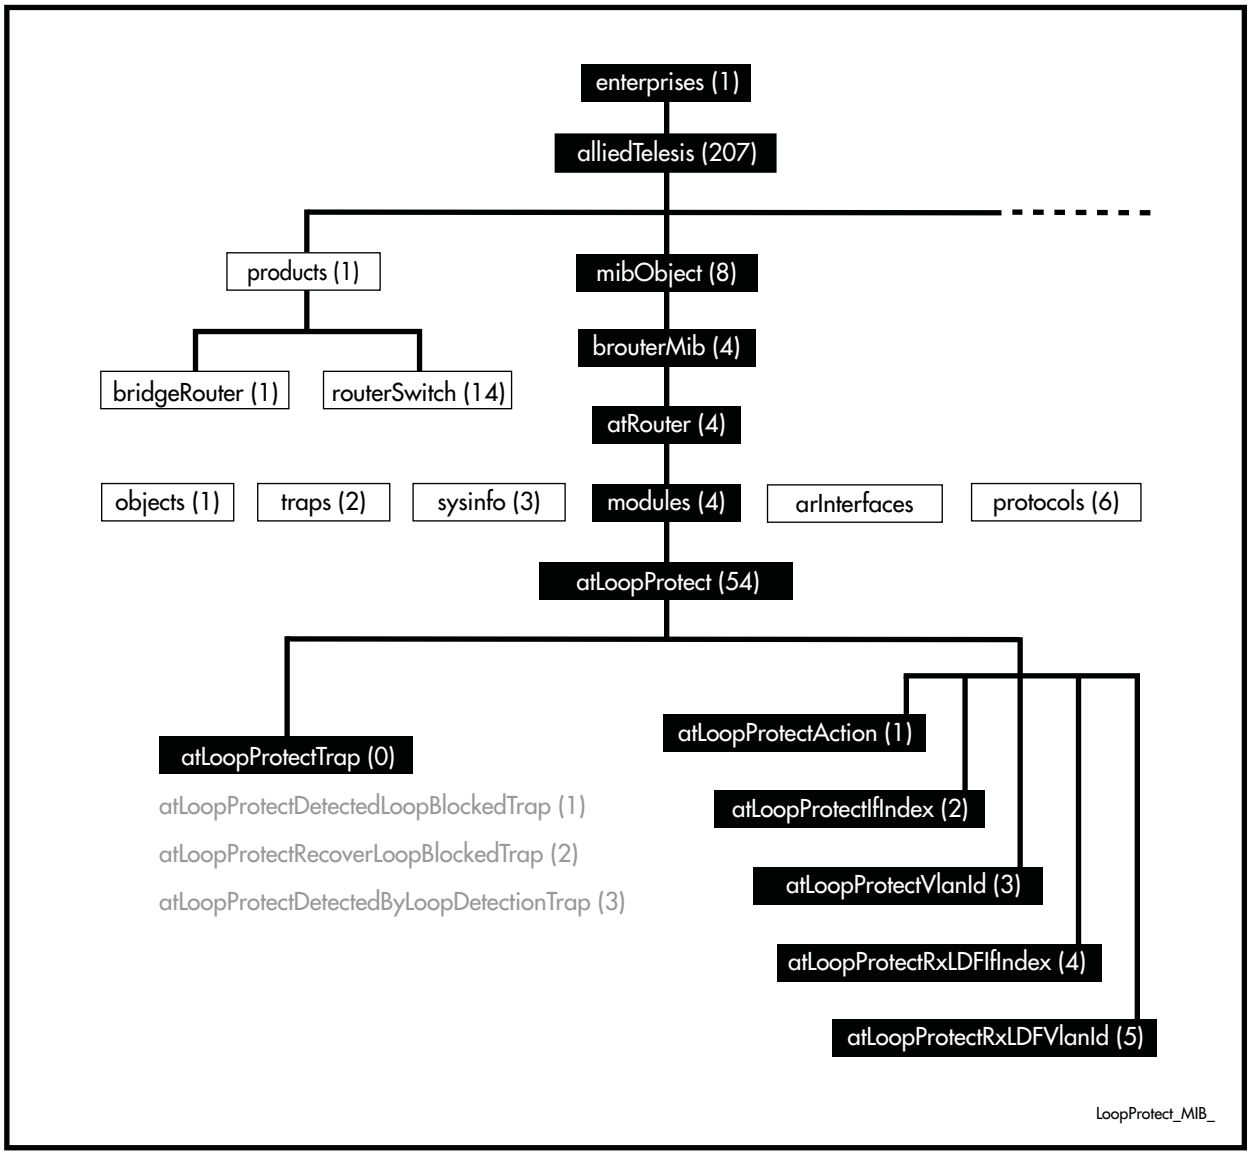

Table 89-16: Objects Defined in the AT-Loop Protect MIB

Object	Object Identifier	Description
{ atLoopProtect }	{ modules 54 }	The root of the Loop Protect object sub tree.
{ atLoopProtectTrap }	{ atLoopProtect0 }	The Loop Protection node state transition trap. List of traps (notifications) generated for Loop Protection.
{ atLoopProtectDetected LoopBlockedTrap }	{ atLoopProtectTrap1 }	Notification generated when the Loop Protection feature blocks an interface with a loop. The following bindings are associated with this trap: ■ atLoopProtectIfIndex ■ atLoopProtectVlanId ■ atLoopProtectAction
{ atLoopProtectRecover LoopBlockedTrap }	{ atLoopProtectTrap2 }	Notification generated when the Loop Protection feature restores a blocked interface back to normal operation. The following bindings are associated with this trap: ■ atLoopProtectIfIndex ■ atLoopProtectVlanId ■ atLoopProtectAction
{ atLoopProtectDetected ByLoopDetectionTrap }	{ atLoopProtectTrap3 }	Notification generated when the Loop Protection feature detects a loop by Loop Detection method. The following bindings are associated with this trap: ■ atLoopProtectIfIndex ■ atLoopProtectVlanId ■ atLoopProtectRxLDFIfIndex ■ atLoopProtectRxLDFVlanId
{ atLoopProtectAction }	{ atLoopProtect1 }	The Action for the Loop Protection feature. The following values are defined: ■ atLoopProtectAction-LearnDisable (0) ■ atLoopProtectAction-LearnEnable (1) ■ atLoopProtectAction-PortDisable (2) ■ atLoopProtectAction-PortEnable (3) ■ atLoopProtectAction-LinkDown (4) ■ atLoopProtectAction-LinkUp (5) ■ atLoopProtectAction-VlanDisable (6) ■ atLoopProtectAction-VlanEnable (7)
{ atLoopProtectIfIndex }	{ atLoopProtect2 }	The interface on which the loop was detected.
{ atLoopProtectVlanId }	{ atLoopProtect3 }	The VLAN ID on which the loop was detected.
{ atLoopProtectRxLDFIfIndex }	{ atLoopProtect4 }	The interface on which the loop detection frame was received.
{ atLoopProtectRxLDFVlanId }	{ atLoopProtect5 }	The VLAN ID on which the loop detection frame was received.

AT-SETUP-MIB

AT-SETUP-MIB defines objects for managing software installation and configuration files (Figure 89-4, Table 89-17). Objects in this group have the object identifier setup ({ modules 500 }). The procedure in Table 87-6 on page 87.23 shows how to use these MIB objects to upgrade to a new software version and boot configuration file. For objects used for file copying, see “AT-FILEv2-MIB” on page 89.56.

Figure 89-4: The AT-SETUP-MIB sub-tree

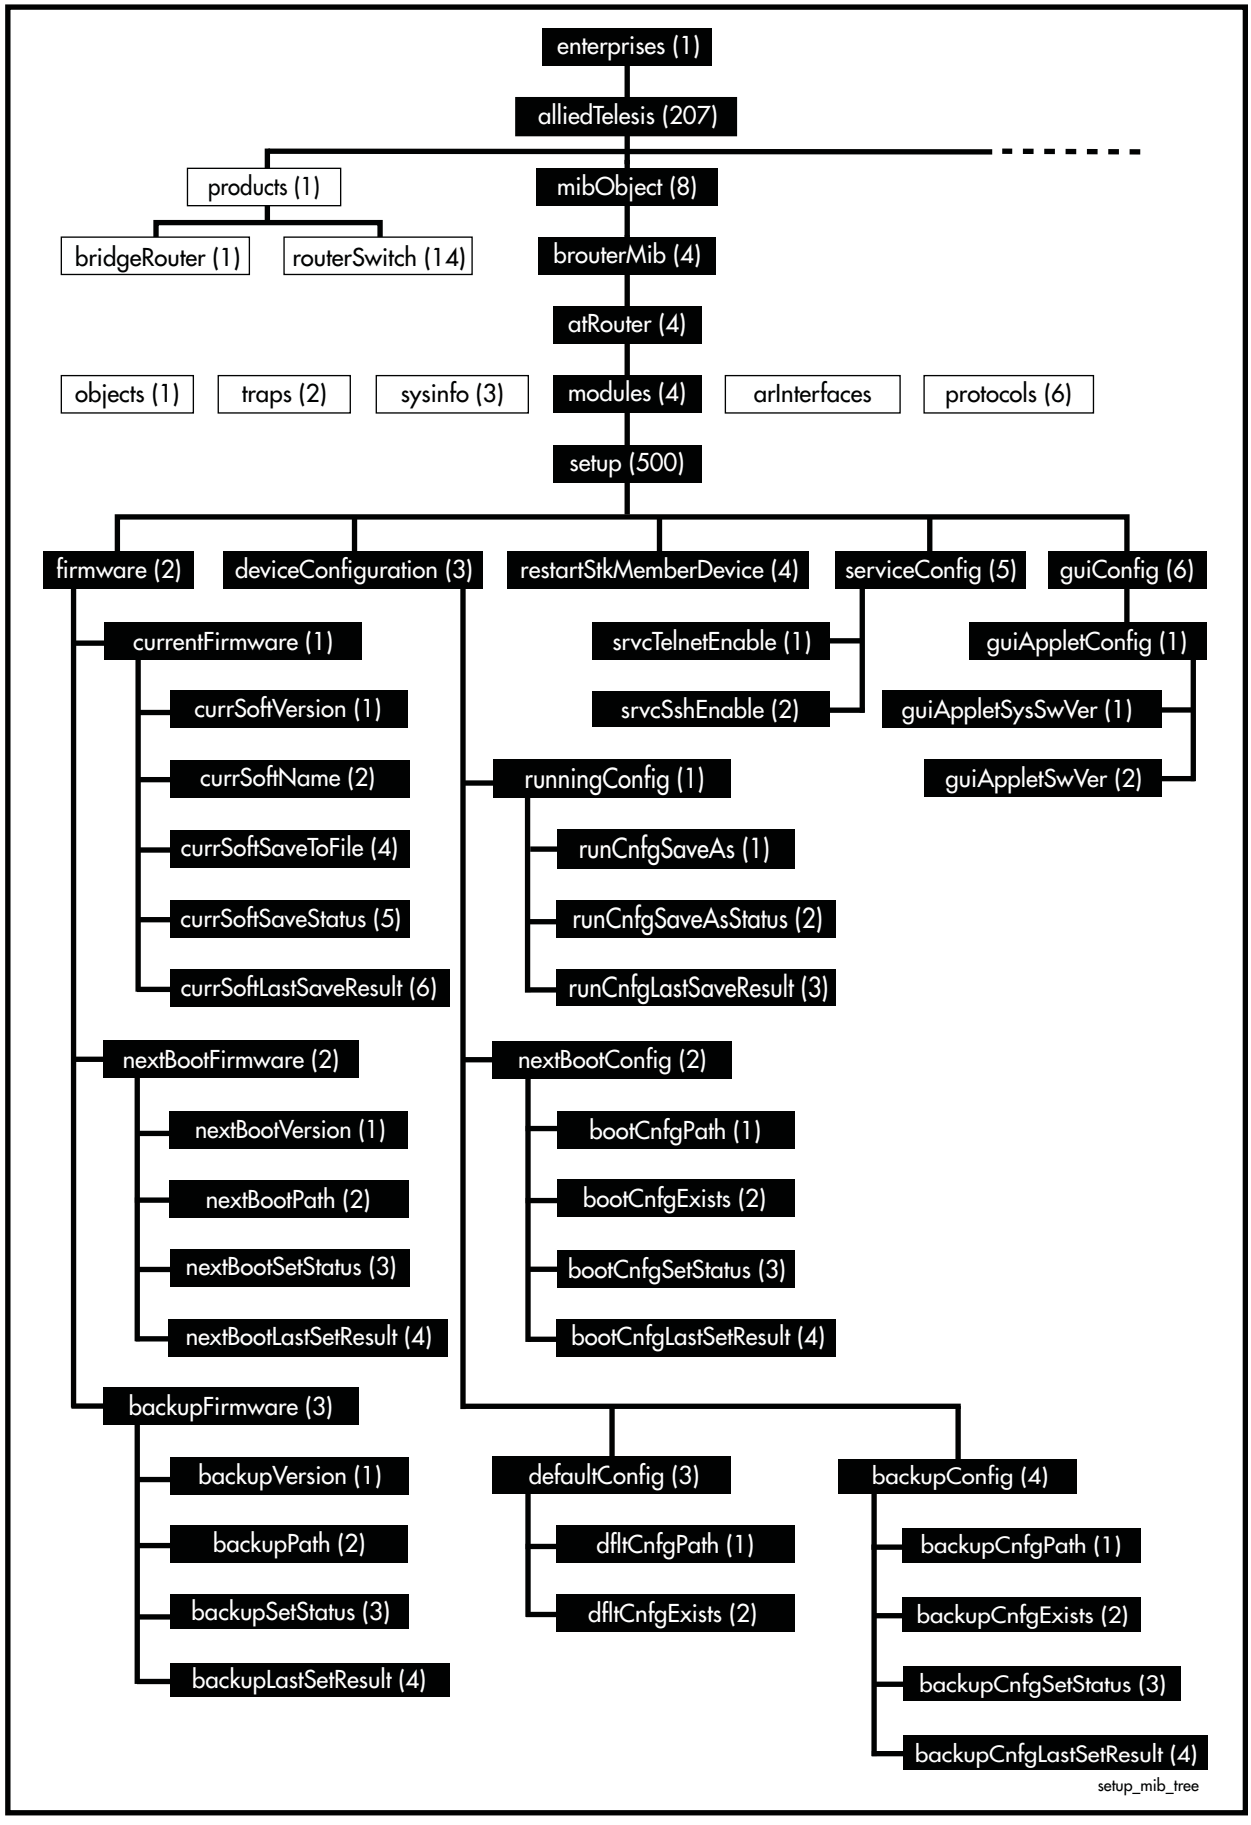

Table 89-17: Objects defined in AT-SETUP-MIB

Object	Object Identifier	Description
firmware	{ setup 2 }	Objects for managing the software version files that the device will install and run.
currentFirmware	{ firmware 1 }	Information about the current software version installed on the device.
currSoftVersion	{ currentFirmware 1 }	Current software version.
currSoftName	{ currentFirmware 2 }	Current software name.
currSoftSaveToFile	{ currentFirmware 4 }	Set with a URL to save the currently running software to the root of Flash or SD card (e.g. 'flash:/filename.rel' or 'card:/filename.rel'). The URL must not contain whitespace characters. Only one save operation can be executed at a time across all SNMP users and an operation may not be started unless the current value of currSoftSaveStatus is 'idle'. Immediately upon executing the set action, the actual firmware save operation is started and will continue on the device until it has completed or a failure occurs. When read, this object will return the URL of the last firmware save operation that was attempted.
currSoftSaveStatus	{ currentFirmware 5 }	This object will return the status of any current operation to store the running software to a release file. The following values may be returned: ■ 1 (idle) - there is no release file save operation in progress ■ 2 (success) - the last release file save operation completed successfully ■ 3 (failure) - the last release file save operation failed ■ 4 (saving) - a release file save operation is currently in progress When a read of this object returns a value of 'success' or 'failure', it will immediately be reset to 'idle' and a new operation may be initiated if desired. A detailed description of the last completed operation may be determined by reading currSoftLastSaveResult.
currSoftLastSaveResult	{ currentFirmware 6 }	Gives an indication of the result of the last completed SNMP operation to save the running firmware to a release file.

Table 89-17: Objects defined in AT-SETUP-MIB(cont.)

Object	Object Identifier	Description
nextBootFirmware	{ firmware 2 }	Information about the software version to be installed on the device when booting.
nextBootVersion	{ nextBootFirmware 1 }	Provides information on the software version (major.minor.interim, for example version 5.4.1) that the device will boot from. A zero will be returned if the version cannot be determined.
nextBootPath	{ nextBootFirmware 2 }	The full path to the release file that will be used the next time the device is rebooted. The URL must not contain whitespace characters. Only one set operation can be executed at a time across all SNMP users and an operation may not be started unless the current value of nextBootSetStatus is 'idle'. Immediately upon executing the set action, the system will attempt to set the new configuration path, and the process will continue on the device until it has completed or a failure occurs. This object can be set with an empty string in order to clear the current boot firmware. Otherwise, the path should be of the form 'flash:/filename.cfg' or 'card:/filename.cfg'. In order to set this object, the file must meet the following conditions: ■ it must exist ■ it must be located in the root of Flash (on the active master in a stacked environment) or SD card ■ it must not be the same as the backup release file ■ it must have a .rel suffix ■ it must pass several internal checks to ensure that it is a genuine release file ■ in a stacked environment, there must be enough disk space available to store the release file on each stack member
nextBootSetStatus	{ nextBootFirmware 3 }	Returns the status of any current operation to set the next boot release file. The following values may be returned: ■ 1 (idle) - there is no boot release setting operation in progress ■ 2 (success) - the last boot release setting operation completed successfully ■ 3 (failure) - the last boot release setting operation failed ■ 5 (syncing) - a boot release setting operation is currently in progress and the file is being synchronized across the stack When a read of this object returns a value of 'success' or 'failure', it will immediately be reset to 'idle' and a new operation may be initiated if desired. A detailed description of the last completed operation may be determined by reading nextBootLastSetResult.
nextBootLastSetResult	{ nextBootFirmware 4 }	Gives an indication of the result of the last completed SNMP operation to set the boot release filename.

Table 89-17: Objects defined in AT-SETUP-MIB(cont.)

Object	Object Identifier	Description
backupFirmware	{ firmware 3 }	Information about the backup software version and path.
backupVersion	{ backupFirmware 1 }	Provides information on the backup software version (major.minor.interim, for example version 5.4.1) that the device will boot from. A zero will be returned if the version cannot be determined.
backupPath	{ backupFirmware 2 }	The full path to the backup release file that will be used the next time the device is rebooted. The URL must not contain whitespace characters. Only one set operation can be executed at a time across all SNMP users and an operation may not be started unless the current value of backupSetStatus is 'idle'. Immediately upon executing the set action, the system will attempt to set the new configuration path, and the process will continue on the device until it has completed or a failure occurs. This object can be set with an empty string in order to clear the current backup firmware. Otherwise, the path should be of the form 'flash:/filename.cfg' or 'card:/filename.cfg'. In order to set this object, the file must meet the following conditions: ■ it must exist ■ it must be located in the root of Flash (on the active master in a stacked environment) or SD card ■ it must not be the same as the configured main release file ■ it must have a .rel suffix ■ it must pass several internal checks to ensure that it is a genuine release file ■ in a stacked environment, there must be enough disk space available to store the release file on each stack member
backupSetStatus	{ backupFirmware 3 }	Returns the status of any current operation to set the backup boot release file. The following values may be returned: ■ 1 (idle) - there is no backup boot release setting operation in progress ■ 2 (success) - the last backup boot release setting operation completed successfully ■ 3 (failure) - the last backup boot release setting operation failed ■ 5 (syncing) - a backup boot release setting operation is currently in progress and the file is being synchronized across the stack When a read of this object returns a value of 'success' or 'failure', it will immediately be reset to 'idle' and a new operation may be initiated if desired. A detailed description of the last completed operation may be determined by reading backupLastSetResult.
backupLastSetResult	{ backupFirmware 4 }	Gives an indication of the result of the last completed SNMP operation to set the backup boot release filename.

Table 89-17: Objects defined in AT-SETUP-MIB(cont.)

Object	Object Identifier	Description
deviceConfiguration	{ setup 3	Objects for managing device configuration.
runningConfig	{ deviceConfiguration 1 }	
runCnfgSaveAs	{ runningConfig 1 }	Set with a URL to save the currently running software to the root of Flash or SD card (e.g. 'flash:/filename.rel' or 'card:/filename.rel'). The URL must not contain whitespace characters. Only one set operation can be executed at a time across all SNMP users and an operation may not be started unless the current value of runCnfgSaveAsStatus is 'idle'. Immediately upon executing the set action, the system will attempt to save the running configuration and the process will continue on the device until it has completed or a failure occurs. When read, this object will return the URL of the last firmware save operation that was attempted.
runCnfgSaveAsStatus	{ runningConfig 2 }	Returns the status of any current operation to save the running configuration. The following values may be returned: ■ 1 (idle) - there is no config file save operation in progress ■ 2 (success) - the last config file save operation completed successfully ■ 3 (failure) - the last config file save operation failed ■ 4 (saving) - a config file save operation is currently in progress When a read of this object returns a value of 'success' or 'failure', it will immediately be reset to 'idle' and a new operation may be initiated if desired. A detailed description of the last completed operation may be determined by reading runCnfgLastSaveResult.
runCnfgLastSaveResult	{ runningConfig 3 }	Gives an indication of the result of the last completed SNMP operation to save the running configuration.

Table 89-17: Objects defined in AT-SETUP-MIB(cont.)

Object	Object Identifier	Description
nextBootConfig	{ deviceConfiguration 2 }	
bootCnfgPath	{ nextBootConfig 1 }	The full path to the configuration file that will be used the next time the device is rebooted. The URL must not contain whitespace characters. Only one set operation can be executed at a time across all SNMP users and an operation may not be started unless the current value of bootCnfgSetStatus is 'idle'. Immediately upon executing the set action, the system will attempt to set the new configuration path, and the process will continue on the device until it has completed or a failure occurs. This object can be set with an empty string in order to clear the current boot configuration. Otherwise, the path should be of the form 'flash:/myconfig.cfg' or 'card:/filename.cfg'. In order to set this object, the file must meet the following conditions: ■ it must exist ■ it must be located in the root of Flash (on the active master in a stacked environment) or SD card ■ it must have a .cfg suffix ■ in a stacked environment, there must be enough disk space available to store the configuration file on each stack member
bootCnfgExists	{ nextBootConfig 2 }	This object will return the value TRUE if the currently defined boot configuration file exists, or FALSE if it does not.
bootCnfgSetStatus	{ nextBootConfig 3 }	Returns the status of any current operation to set the next boot configuration file. The following values may be returned: ■ 1 (idle) - there is no boot configuration setting operation in progress ■ 2 (success) - the last boot configuration setting operation completed successfully ■ 3 (failure) - the last boot configuration setting operation failed ■ 5 (syncing) - a boot configuration setting operation is currently in progress and the file is being synchronized across the stack When a read of this object returns a value of 'success' or 'failure', it will immediately be reset to 'idle' and a new operation may be initiated if desired. A detailed description of the last completed operation may be determined by reading bootCnfgLastSetResult.
bootCnfgLastSetResult	{ nextBootConfig 4 }	Gives an indication of the result of the last completed SNMP operation to set the boot configuration filename.

Table 89-17: Objects defined in AT-SETUP-MIB(cont.)

Object	Object Identifier	Description
defaultConfig	{ deviceConfiguration 3 }	
dfltCnfgPath	{ defaultConfig 1 }	The full path of the configuration file to use as backup when the device is rebooted. This object is not settable. The default configuration file is always 'flash:/default.cfg'.
dfltCnfgExists	{ defaultConfig 2 }	This object will return the value TRUE if the currently defined default configuration file exists, or FALSE if it does not.

Table 89-17: Objects defined in AT-SETUP-MIB(cont.)

Object	Object Identifier	Description
backupConfig	{ deviceConfiguration 4 }	
backupCnfgPath	{ backupConfig 1 }	The full path to the backup configuration file that will be used the next time the device is rebooted. The URL must not contain whitespace characters. Only one set operation can be executed at a time across all SNMP users and an operation may not be started unless the current value of backupCnfgSetStatus is 'idle'. Immediately upon executing the set action, the system will attempt to set the new backup configuration path, and the process will continue on the device until it has completed or a failure occurs. This object can be set with an empty string in order to clear the current boot configuration. Otherwise, the path should be of the form 'flash:/myconfig.cfg' or 'card:/filename.cfg'. In order to set this object, the file must meet the following conditions: ■ it must exist ■ it must be located in the root of Flash (on the active master in a stacked environment) or SD card ■ it must have a .cfg suffix ■ in a stacked environment, there must be enough disk space available to store the configuration file on each stack member
backupCnfgExists	{ backupConfig 2 }	This object will return the value TRUE if the currently defined backup configuration file exists, or FALSE if it does not.
backupCnfgSetStatus	{ backupConfig 3 }	Returns the status of any current operation to set the next backup boot configuration file. The following values may be returned: ■ 1 (idle) - there is no backup boot configuration setting operation in progress ■ 2 (success) - the last backup boot configuration setting operation completed successfully ■ 3 (failure) - the last backup boot configuration setting operation failed ■ 5 (syncing) - a backup boot configuration setting operation is currently in progress and the file is being synchronized across the stack When a read of this object returns a value of 'success' or 'failure', it will immediately be reset to 'idle' and a new operation may be initiated if desired. A detailed description of the last completed operation may be determined by reading backupCnfgLastSetResult.
backupCnfgLastSetResult	{ backupConfig 4 }	Gives an indication of the result of the last completed SNMP operation to set the backup boot configuration filename.

Table 89-17: Objects defined in AT-SETUP-MIB(cont.)

Object	Object Identifier	Description
restartStkMemberDevice	{ setup 4 }	This object causes a specified device to restart immediately. The restart is initiated by setting its value to the device's stack member ID. Setting its value to zero will cause all devices in the stack, or a standalone device, to restart. Reading the object will always return zero.
serviceConfig	{ setup 5 }	
srvcTelnetEnable	{ serviceConfig 1 }	This object is used to either read or set the state of the telnet server on a device. Telnet can be enabled by setting the value of this object to 'enable(1)' or can be disabled by setting the value 'disable(2)'.
srvcSshEnable	{ serviceConfig 2 }	This object is used to either read or set the state of the SSH server on a device. SSH can be enabled by setting the value of this object to 'enable(1)' or can be disabled by setting the value 'disable(2)'.
guiConfig	{ setup 6 }	
guiAppletConfig	{ guiConfig 1 }	
guiAppletSysSwVer	{ guiAppletConfig 1 }	This object represents the system software release that the currently selected GUI applet was designed to run on. The system automatically searches for GUI applet files that reside in the root directory of the Flash memory, and selects the latest available file that is applicable to the currently running system software. This is the applet that will be uploaded to a user's web browser when they initiate the GUI.
	{ guiAppletConfig 2 }	This object represents the software version of the currently selected GUI applet. The system automatically searches for GUI applet files residing in the root directory of the Flash memory, and selects the latest available one that is applicable to the currently running system software. This is the applet that will be uploaded to a user's web browser when they initiate the GUI.

AT-DNS-CLIENT-MIB

AT-DNS-CLIENT-MIB contains definitions of managed objects for the Allied Telesis DNS Client Configuration.

Objects in this group have the object identifier atDns ({ Modules 501 }). Table 89-18 lists the objects supported by the AlliedWare Plus™ Operating System.

Table 89-18: Objects defined in AT-DNS-CLIENT-MIB

Object	Object Identifier	Description
atDnsClient	{ atDns 1 }	MIB File for DNS Client Configuration.
atDNSServerIndexNext	{ atDnsClient 1 }	The next available value for the object 'atDNSServerIndex'. The value is used by a management application to create an entry in the 'atDNSServerTable'.
atDNSServerTable	{ atDnsClient 2 }	Table of information about the Domain Name System (DNS) Server configurations in the system, indexed by 'atDNSServerIndex'.
atDNSServerEntry	{ atDNSServerTable 1 }	Information about a single DNS Server Configuration.
atDNSServerIndex	{ atDNSServerEntry 1 }	The index corresponding to the particular DNS Server Configuration. When creating a new entry in the table, the value of this object must be equal to the value in the 'atDNSServerIndexNext'.
atDNSServerAddrType	{ atDNSServerEntry 2 }	The Internet Address Type of the 'atDNSServerAddr' object. Can be one of the following: ■ unknown (0) ■ ipv4 (1) - default ■ ipv6 (2) - not supported ■ ipv4z (3) - not supported ■ ipv6z (4) - not supported ■ dns (16) - not supported
atDNSServerAddr	{ atDNSServerEntry 3 }	The IP Address of the DNS Server. When a new entry is created, this object is set to the default of '0.0.0.0' { '00000000'h }. The management application will change this to the desired value using a SET operation.
atDNSServerStatus	{ atDNSServerEntry 4 }	The status of the current entry (row). Can be one of the following: ■ active (1) ■ createAndGo (4) ■ destroy (6) To create a new entry the management application must set this object with value 'createAndGo (4)'. To delete an entry, the management application must set this object with value 'destroy (6)'. Once an entry is deleted, all subsequent entries in the table will be renumbered. The default is 1 (active)

AT-NTP-MIB

This MIB contains objects for managing the Allied Telesis Network Time Protocol (NTP) configuration (Table 89-19). The objects reside in the module atNtp { modules 502 }, organized in the following groups:

- NTP Peer/Server Table - a table containing information on the Network Time Protocol (NTP) peers or server configurations in the system.
- Associations Table - a list of installed software; used also to remove software from the device.
- Status Table - Objects in this group are not supported.

Table 89-19: Objects defined in AT-NTP-MIB

Object	Object Identifier	Description
atNtp	{ modules 502 }	MIB containing objects for configuring NTP.
atNtpPeerIndexNext	{ atNtp 6 }	The next available index number to be used for object 'atNtpPeerIndex'.
atNtpPeerTable	{ atNtp 7 }	Table containing information on the Network Time Protocol (NTP) peers or server configurations in the system. Indexed by: ■ atNtpPeerIndex
atNtpPeerEntry	{ atNtpPeerTable 1 }	Information about a single NTP server or peer configuration.
atNtpPeerIndex	{ atNtpPeerEntry 1 }	The index number corresponding to a particular NTP server or peer configuration in the system. To create a new entry, the value of this object should be the same as that of the value of atNtpPeerIndexNext object, otherwise the entry creation will fail.
atNtpPeerNameAddr	{ atNtpPeerEntry 2 }	The host name, or the IP address of the NTP peer. When a new row (entry) is created, this object is set with a default of '0.0.0.0', and the management application should change it to a desired value by using a SET operation.
atNtpPeerMode	{ atNtpPeerEntry 3 }	The mode of the peer. Can be one of the following: ■ server (1) ■ peer (2) - default
atNtpPeerPreference	{ atNtpPeerEntry 4 }	The values in this object specifies whether this peer is the preferred one. Valid values are 0 to 2: ■ 0 - unknown - default ■ 1 - not preferred ■ 2 - preferred When the value is 'not preferred' (1) NTP chooses the peer with which to synchronize the time on the local system. If the object is set to 'preferred' (2) NTP will choose the corresponding peer to synchronize the time with.

Table 89-19: Objects defined in AT-NTP-MIB(cont.)

Object	Object Identifier	Description
atNtpPeerVersion	{ atNtpPeerEntry 5 }	The NTP version the peer supports. Can be one of the following: ■ 0 - unknown - default ■ 1 - version 1 ■ 2 - version 2 ■ 3 - version 3 ■ 4 - version 4
atNtpPeerKeyNumber	{ atNtpPeerEntry 6 }	The authentication key number. Default number is 0.
atNtpPeerRow Status	{ atNtpPeerEntry 7 }	The current status of this peer entry. The following values may be returned when reading this object: ■ active (1) - this value is returned on reading of this entry. ■ createAndGo (4) - this value is set by the management application when creating a new entry ■ destroy (6) - value set by the management application when deleting the entry. When an entry is deleted, all subsequent entries in the table will be re-indexed.
atNtpAssociationTable	{ atNtp 10 }	Table containing information on the Network Time Protocol (NTP) associations. Indexed by: ■ atNtpAssociationIndex
atNtpAssociationEntry	{ atNtpAssociationTable 1 }	Information about a single NTP server or peer configuration.
atNtpAssociationIndex	{ atNtpAssociationEntry 1 }	The index number corresponding to a particular NTP server or peer configuration in the system. To create a new entry, the value of this object should be the same as that of the value of atNtpPeerIndexNext object, otherwise the entry creation will fail.
atNtpAssociationPeerAddr	{ atNtpAssociationEntry 2 }	The host name, or the IP address of the NTP peer. When a new row (entry) is created, this object is set with a default of '0.0.0.0', and the management application should change it to a desired value by using a SET operation.
atNtpAssociationStatus	{ atNtpAssociationEntry 3 }	The status of this association. Can be one of the following: ■ master (synced) ■ master (unsynced) ■ selected ■ candidate ■ configured ■ unknown
atNtpAssociationConfigured	{ atNtpAssociationEntry 4 }	The value in this object specifies whether the association is from configuration or not. Value can be: ■ configured ■ dynamic
atNtpAssociationRefClkAddr	{ atNtpAssociationEntry 5 }	The IP Address for the reference clock.
atNtpAssociationStratum	{ atNtpAssociationEntry 6 }	The stratum of the peer clock.

Table 89-19: Objects defined in AT-NTP-MIB(cont.)

Object	Object Identifier	Description
atNtpAssociationPoll	{ atNtpAssociationEntry 7 }	The time between NTP requests from the device to the server, in seconds.
atNtpAssociationReach	{ atNtpAssociationEntry 8 }	An integer that indicates the reachability status of the peer.
atNtpAssociationDelay	{ atNtpAssociationEntry 9 }	The round trip delay between the device and the server.
atNtpAssociationOffset	{ atNtpAssociationEntry 10 }	The difference between the device clock and the server clock.
atNtpAssociationDisp	{ atNtpAssociationEntry 11 }	The lowest measure of error associated with peer offset, based on delay, in seconds.
atNtpStatus	{ atNtp 11 }	Group of objects containing system status information. The objects in this group are not supported.
atNtpSysClockSync	{ atNtpStatus 1 }	Not supported.
atNtpSysStratum	{ atNtpStatus 2 }	Not supported.
atNtpSysReference	{ atNtpStatus 3 }	Not supported.
atNtpSysFrequency	{ atNtpStatus 4 }	Not supported.
atNtpSysPrecision	{ atNtpStatus 5 }	Not supported.
atNtpSysRefTime	{ atNtpStatus 6 }	Not supported.
atNtpSysClkOffset	{ atNtpStatus 7 }	Not supported.
atNtpSysRootDelay	{ atNtpStatus 8 }	Not supported.
atNtpSysRootDisp	{ atNtpStatus 9 }	Not supported.

AT-EPSRv2-MIB

The EPSRv2 Group-MIB defines objects for managing Epsrv2 objects and triggers (Figure 89-5, Table 89-20). Objects in this group have the object identifier Epsrv2 ({ modules 536 }).

Figure 89-5: The AT-EPSRv2 MIB sub-tree

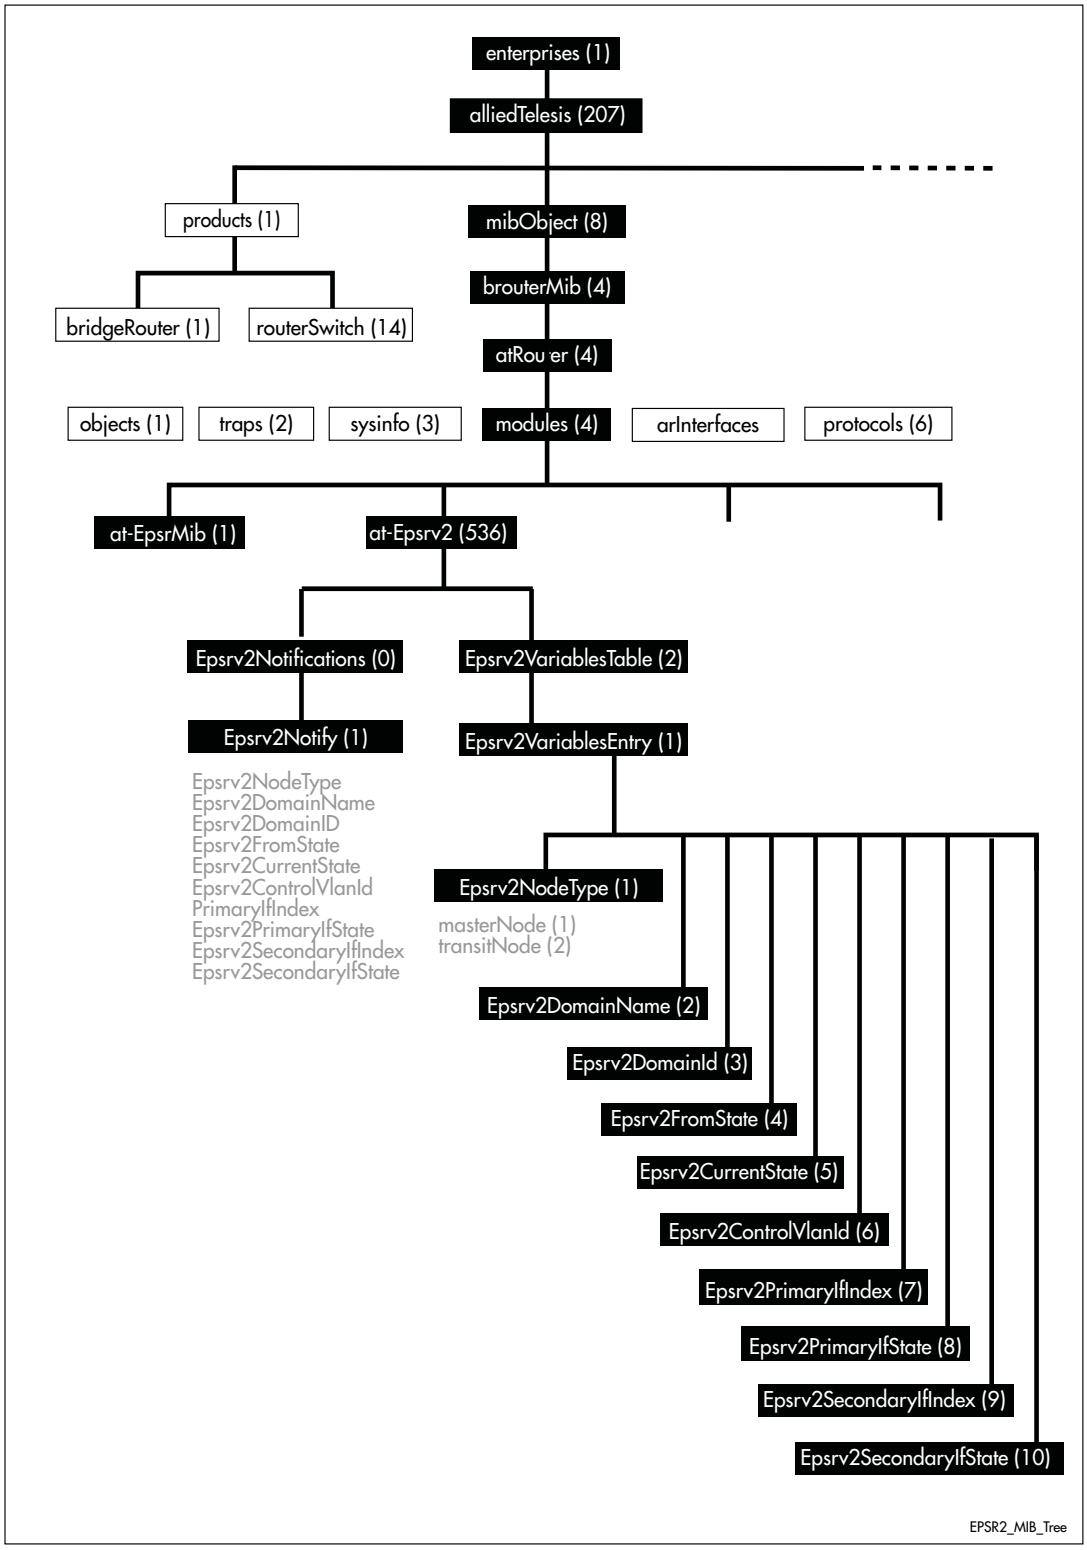

Table 89-20: atEpsrv2Objects Defined in the AT-EPSRV2 MIB

Object	Object Identifier	Description
{ at-Epsrv2 }	{ modules 536 }	The root of the Epsrv2 object sub tree.
{ atEpsrv2Notifications }	{ at-Epsrv2 0 }	
{ atEpsrv2Notify }	{ atEpsrv2Notifications 1 }	EPSR Master/Transit node state transition trap. Note that there is a one to one relationship between nodes and domains.
{ Epsrv2NodeType }	{ atEpsrv2VariablesEntry 1 }	The EPSR node type: either master or transit.
{ atEpsrv2DomainName }	{ atEpsrv2VariablesEntry 2 }	The name of the EPSR domain.
{ atEpsrv2DomainID }	{ atEpsrv2VariablesEntry 3 }	The ID of the EPSR domain.
{ Epsrv2FromState }	{ atEpsrv2VariablesEntry 4 }	The previous state of the EPSR domain
{ Epsrv2Current State }	{ atEpsrv2VariablesEntry 5 }	The current state of the EPSR domain.
{ Epsrv2ControlVlanId }	{ atEpsrv2VariablesEntry 6 }	The VLAN identifier for the control VLAN.
{ Epsrv2PrimaryIfIndex }	{ atEpsrv2VariablesEntry 7 }	The IfIndex of the primary interface.
{ atEpsrv2PrimaryIfState }	{ atEpsrv2VariablesEntry 8 }	The current state of the primary interface.
{ atEpsrv2SecondaryIfIndex }	{ atEpsrv2VariablesEntry 9 }	The IfIndex of the secondary interface.
{ atEpsrv2SecondaryIfState }	{ atEpsrv2VariablesEntry 10 }	The state of the secondary interface.
{ atEpsrv2VariablesTable }	{ at-Epsrv2 2 }	The enterprise Epsrv2VariablesTable.
{ atEpsrv2VariablesEntry }	{ atEpsrv2VariablesTable 1}	Contains entries within the enterprise atEpsrv2VariablesTable.
{ atEpsrv2NodeType }	{ atEpsrv2VariablesEntry 1 }	The EPSR domain node type: either ■ master (1) ■ transit (2)
{ atEpsrv2DomainName }	{ Epsrv2NodeType 2 }	The name of the EPSR domain.
{ atEpsrv2DomainID }	{ Epsrv2NodeType 3 }	The ID of the EPSR domain.
{ atEpsrv2FromState }	{ Epsrv2NodeType 4 }	The previous state of the EPSR domain
{ atEpsrv2Current State }	{ Epsrv2NodeType 5 }	The current state of the EPSR domain.
{ atEpsrv2ControlVlanId }	{ Epsrv2NodeType 6 }	The VLAN identifier for the control VLAN.
{ Epsrv2PrimaryIfIndex }	{ Epsrv2NodeType 7 }	The IfIndex of the primary interface.
{ atEpsrv2PrimaryIfState }	{ Epsrv2NodeType 8 }	The current state of the primary interface.
{ atEpsrv2SecondaryIfIndex }	{ Epsrv2NodeType 9 }	The IfIndex of the secondary interface.
{ atEpsrv2SecondaryIfState }	{ Epsrv2NodeType 10 }	The state of the secondary interface.
TEXTUAL CONVENTIONS		
{ atEpsrv2NodeState }		The trap states that can be advertised for an EPSR domain node. The following states are defined: ■ idle (1) ■ complete (2) ■ failed (3) ■ linksUp (4) ■ linksDown (5) ■ preForward (6) ■ unknown (7)
{ atEpsrv2InterfaceState }		The trap states that can be advertised for an EPSR interface. The following states are defined: ■ unknown (1) ■ down (2) ■ blocked (3) ■ forward (4)

AT-DHCPSN-MIB

This MIB contains objects for displaying and managing DHCP snooping and ARP security information on the switch. (Table 89-21). The objects reside in the module atDhcpsn { modules 537 }, organized in the following groups:

- The DHCP Snooping Events group (atDhcpsnEvents) contains notifications (traps)
- The DHCP Snooping table (atDhcpsnVariablesTable) contains DHCP snooping information
- The ARP Security table (atArpsecVariablesTable) contains ARP security information

Table 89-21: Objects defined in AT-DHCPSN-MIB

Object	Object Identifier	Description
atDhcpsn	{ modules 537 }	This MIB file contains definitions of managed objects for DHCP Snooping in AlliedWare Plus™.
atDhcpsnEvents	{ atDhcpsn 1 }	DHCP Snooping notifications (traps)
atDhcpsnTrap	{ atDhcpsnEvents 1 }	DHCP Snooping violation notification.
atArpsecTrap	{ atDhcpsnEvents 2 }	DHCP Snooping ARP Security violation notification.
atDhcpsnVariablesTable	{ atDhcpsn 1 }	The DHCP Snooping table. This table contains rows of DHCP Snooping information.
atDhcpsnVariablesEntry	{ atDhcpsnVariablesTable 1 }	A set of parameters that describe the DHCP Snooping features.
atDhcpsnIfIndex	{ atDhcpsnVariablesEntry 1 }	Ifindex of the port that the packet was received on.
atDhcpsnVid	{ atDhcpsnVariablesEntry 2 }	VLAN ID of the port that the packet was received on.
atDhcpsnSmac	{ atDhcpsnVariablesEntry 3 }	Source MAC address of the packet that caused the trap.
atDhcpsnOpcode	{ atDhcpsnVariablesEntry 4 }	Opcode value of the BOOTP packet that caused the trap. Only bootpRequest(1) or bootpReply(2) is valid.
atDhcpsnCiaddr	{ atDhcpsnVariablesEntry 5 }	Ciaddr value of the BOOTP packet that caused the trap.
atDhcpsnYiaddr	{ atDhcpsnVariablesEntry 6 }	Yiaddr value of the BOOTP packet that caused the trap.
atDhcpsnGiaddr	{ atDhcpsnVariablesEntry 7 }	Giaddr value of the BOOTP packet that caused the trap.
atDhcpsnSiaddr	{ atDhcpsnVariablesEntry 8 }	Siaddr value of the BOOTP packet that caused the trap.
atDhcpsnChaddr	{ atDhcpsnVariablesEntry 9 }	Chaddr value of the BOOTP packet that caused the trap.

Table 89-21: Objects defined in AT-DHCPSN-MIB(cont.)

Object	Object Identifier	Description
atDhcpsnVioType	{ atDhcpsnVariablesEntry 10 }	The reason that the trap was generated. ■ invalidBootp(1) indicates that the received BOOTP packet was invalid. For example, it is neither BootpRequest nor BootpReply. ■ invalidDhcpAck(2) indicates that the received DHCP ACK was invalid. ■ invalidDhcpRelDec(3) indicates the DHCP Release or Decline was invalid. ■ invalidIp(4) indicates that the received IP packet was invalid. ■ maxBindExceeded(5) indicates that if the entry was added, the maximum bindings configured for the port would be exceeded. ■ opt82InsertErr(6) indicates that the insertion of Option 82 failed. ■ opt82RxInvalid(7) indicates that the received Option 82 information was invalid. ■ opt82RxUntrusted(8) indicates that Option 82 information was received on an untrusted port. ■ opt82TxUntrusted(9) indicates that Option 82 would have been transmitted out an untrusted port. ■ replyRxUntrusted(10) indicates that a BOOTP Reply was received on an untrusted port. ■ srcMacChaddrMismatch(11) indicates that the source MAC address of the packet did not match the BOOTP CHADDR of the packet. ■ staticEntryExisted(12) indicates that the static entry to be added already exists. ■ dbAddErr(13) indicates that adding an entry to the database failed.
atArpsecVariablesTable	{ atDhcpsn 2 }	The ARP Security table. This table contains rows of DHCP Snooping ARP Security information.
atArpsecVariablesEntry	{ atArpsecVariablesTable 1 }	A set of parameters that describe the DHCP Snooping ARP Security features.
atArpsecIfIndex	{ atArpsecVariablesEntry 1 }	Ifindex of the port that the ARP packet was received on.
atArpsecClientIP	{ atArpsecVariablesEntry 2 }	Source IP address of the ARP packet.
atArpsecSrcMac	{ atArpsecVariablesEntry 3 }	Source MAC address of the ARP packet.
atArpsecVid	{ atArpsecVariablesEntry 4 }	VLAN ID of the port that the ARP packet was received on.

Table 89-21: Objects defined in AT-DHCPSN-MIB(cont.)

Object	Object Identifier	Description
atArpsecVioType	{ atArpsecVariablesEntry 5 }	The reason that the trap was generated. ■ srcIpNotFound(1) indicates that the Sender IP address of the ARP packet was not found in the DHCP Snooping database. ■ badVLAN(2) indicates that the VLAN of the DHCP Snooping binding entry associated with the Sender IP address of the ARP packet does not match the VLAN that the ARP packet was received on. ■ badPort(3) indicates that the port of the DHCP Snooping binding entry associated with the Sender IP address of the ARP packet does not match the port that the ARP packet was received on. ■ srcIpNotAllocated(4) indicates that the CHADDR of the DHCP Snooping binding entry associated with the Sender IP address of the ARP packet does not match the Source MAC and/or the ARP source MAC of the ARP packet.

AT-FILEv2-MIB

This MIB contains objects for displaying and managing file content of Flash, NVS and SD cards on local and stacked devices, and copying, moving and deleting files from local, stacked and remote sources (Table 89-22).

The objects reside in the module atFilev2 { modules 600 }, organized in the following groups:

- The file operation devices - object for various devices supported for file operations
- The SD Card Table - information about the SD Cards configured on the device
- The File Info Table - information about all files, including pathnames, that are present on the device

The procedure in "Copy a File to or from a TFTP Server" on page 87.21 shows how to use these MIB objects to upgrade to a new software version and boot configuration file.

Table 89-22: Objects defined in AT-FILEv2-MIB

Object	Object Identifier	Description
atFilev2	{ modules 600 }	MIB containing objects for listing and managing files.
atFilev2FileOperation	{ atFilev2 3 }	Collection of file operation objects available for configuration, to enable copying, moving and deleting files.
atFilev2SourceStackID	{ atFilev2Operation 1 }	Specifies the Stack ID of the source file. Set an integer corresponding to the stack ID of the stack member to use as the source. For devices that are not capable of being stacked, set with the value 1. This value is ignored if the source device is set to TFTP.
atFilev2SourceDevice	{ atFilev2Operation 2 }	Specifies the source device for the file to be copied. Valid values are 1 to 4. Set a value that corresponds with the various devices, as below: ■ 1 - Flash - default ■ 2 - Card ■ 3 - NVS ■ 4 - TFTP For copying files, you may use any combination of devices for the source and destination, except for copying from TFTP to TFTP. For moving files you cannot use TFTP as source or destination. For deleting files, the source cannot be TFTP. You must fully configure all required parameters before an operation can commence. Where a TFTP operation is configured, an IP address must also be set via atFilev2TftpIPAddr. To copy a file from TFTP to Flash, use 4 for source and 1 for destination.
atFilev2SourceFilename	{ atFilev2Operation 3 }	Specifies the filename of the source file to copy, move or delete. Include any path as required, but the storage type is not necessary. For example, to copy the file `latest.cfg` from the backupconfigs/routers directory on the TFTP server, you would set: `backupconfigs/routers/latest.cfg`

Table 89-22: Objects defined in AT-FILEv2-MIB(cont.)

Object(cont.)	Object Identifier	Description
atFilev2DestinationStackID	{ atFilev2Operation 4 }	Specifies the Stack ID for the destination file. For devices that are not capable of being stacked, set with the value 1. This value is ignored if the destination device is set to TFTP, or if a deletion operation is carried out.
atFilev2DestinationDevice	{ atFilev2Operation 5 }	Specifies the destination device for the files to be copied into. Valid values are 1 to 4. Set a value that corresponds with the various devices, as below: ■ 1 - Flash - default ■ 2 - Card ■ 3 - NVS ■ 4 - TFTP For copying files, you may use any combination of devices for the source and destination, except for copying from TFTP to TFTP. For moving files you cannot use TFTP as source or destination. For deleting files, this object is ignored. You must fully configure all required parameters before an operation can commence. Where a TFTP operation is configured, an IP address must also be set via atFilev2TftpIPAddr. To copy a file from TFTP to Flash, use 4 for source and 1 for destination.
atFilev2DestinationFilename	{ atFilev2Operation 6 }	Specifies the destination filename of the file to be copied or moved. Include any path as required, but the storage type is not necessary. The destination filename does not need to be the same as the source filename, and this object is ignored for file deletion operations. For example, to copy a release file from the TFTP server to the backup release directory on Flash, you would set: `backuprelease/latest.rel` Note: If the destination is set to Flash, card or NVS, any file at the destination that shares the destination filename will be overwritten by a move or copy operation.

Table 89-22: Objects defined in AT-FILEv2-MIB(cont.)

Object(cont.)	Object Identifier	Description
atFilev2CopyBegin	{ atFilev2Operation 7 }	Represents the status of the copy file operation, in the form of octet string. A read on this object can return several possible values, depending on the current status of the system and the various file operation objects: ■ idle - There is no file operation in progress and all required objects have been set correctly. Setting a '1' to this object will begin the file copy. ■ Error codes: [1-7] - A copy operation cannot be started until these errors are resolved. See below for key. ■ [action]ing x [--> y] - A file operation is currently in progress. You cannot start another operation while the object is returning this value. ■ [action] x [--> y] success - The last copy, move or delete operation was successfully completed. ■ [action] x [--> y] failure: [err] - The last copy, move or delete operation failed, with the error message attached. Common failures include lack of space on the destination file system, incorrect source file names or communication errors with remote services. Upon reading a success or failure message, the message will be cleared and the next read will result in either an 'idle' message or an 'Error codes' message if not all required objects have been correctly set. If the read returned 'idle', a new file operation can now be started. Following are possible values returned as Error codes for file copy: ■ 1 - atFilev2SourceDevice has not been set ■ 2 - atFilev2SourceFilename has not been set ■ 3 - atFilev2DestinationDevice has not been set ■ 4 - atFilev2DestinationFilename has not been set ■ 5 - atFilev2SourceDevice and atFilev2DestinationDevice are both set to TFTP ■ 6 - the combination of source device, stackID and filename is the same as the destination device, stackID and filename (i.e. it is not valid to copy a file onto itself. ■ 7 - TFTP IP address has not been set and TFTP has been set for one of the devices Provided all above requirements are met, immediately upon executing the SNMP set, the device will indicate that it was a success. The actual file copy itself will be started and continue on the device until it has completed. For large files, operations can take several minutes to complete. Subsequent reads of the object will return one of messages shown in the first table, to allow for tracking of the progress of the copy operation.

Table 89-22: Objects defined in AT-FILEv2-MIB(cont.)

Object(cont.)	Object Identifier	Description
atFilev2MoveBegin	{ atFilev2Operation 8 }	Represents the status of the move file operation, in the form of octet string. A read on this object can return several possible values, depending on the current status of the system and the various file operation objects: ■ idle - There is no file operation in progress and all required objects have been set correctly. Setting a '1' to this object will begin the file move. ■ Error codes: [1-6] - A move operation cannot be started until these errors are resolved. See below for key. ■ [action]ing x [--> y] - A file operation is currently in progress. You cannot start another operation while the object is returning this value. ■ [action] x [--> y] success - The last copy, move or delete operation was successfully completed. ■ [action] x [--> y] failure: [err] - The last copy, move or delete operation failed, with the error message attached. Common failures include lack of space on the destination file system, incorrect source file names or communication errors with remote services. Upon reading a success or failure message, the message will be cleared and the next read will result in either an 'idle' message or an 'Error codes' message if not all required objects have been correctly set. If the read returned 'idle', a new file operation can now be started. Following are possible values returned as Error codes for file move: ■ 1 - atFilev2SourceDevice has not been set ■ 2 - atFilev2SourceFilename has not been set ■ 3 - atFilev2DestinationDevice has not been set ■ 4 - atFilev2DestinationFilename has not been set ■ 5 - either atFilev2SourceDevice or atFilev2DestinationDevice are set to TFTP ■ 6 - the combination of source device, stackID and filename is the same as the destination device, stackID and filename (i.e. it is not valid to move a file onto itself. Provided all above requirements are met, immediately upon executing the SNMP set, the device will indicate that it was a success. The actual file move itself will be started and continue on the device until it has completed. For large files, operations can take several minutes to complete. Subsequent reads of the object will return one of messages shown in the first table, to allow for tracking of the progress of the move operation.

Table 89-22: Objects defined in AT-FILEv2-MIB(cont.)

Object(cont.)	Object Identifier	Description
atFilev2DeleteBegin	{ atFilev2Operation 9 }	Represents the status of the delete file operation, in the form of octet string. A read on this object can return several possible values, depending on the current status of the system and the various file operation objects: ■ idle - There is no file operation in progress and all required objects have been set correctly. Setting a '1' to this object will begin the file deletion. ■ Error codes: [1-3] - A delete operation cannot be started until these errors are resolved. See below for key. ■ [action]ing x [--> y] - A file operation is currently in progress. You cannot start another operation while the object is returning this value. ■ [action] x [--> y] success - The last copy, move or delete operation was successfully completed. ■ [action] x [--> y] failure: [err] - The last copy, move or delete operation failed, with the error message attached. Common failures include lack of space on the destination file system, incorrect source file names or communication errors with remote services. Upon reading a success or failure message, the message will be cleared and the next read will result in either an 'idle' message or an 'Error codes' message if not all required objects have been correctly set. If the read returned 'idle', a new file operation can be started. File deletion operations ignore the values set in the atFilev2DestinationStackID, atFilev2DestinationDevice and atFilev2DestinationFilename objects. The file deletion operation is equivalent to the CLI 'delete force [file]' command, so it is possible to delete any normally-protected system files, such as the currently configured boot release. Following are possible values returned as Error codes for file move: ■ 1 - atFilev2SourceDevice has not been set ■ 2 - atFilev2SourceFilename has not been set ■ 3 - atFilev2SourceDevicehas not been set to TFTP Provided all above requirements are met, immediately upon executing the SNMP set, the device will indicate that it was a success. The actual file move itself will be started and continue on the device until it has completed. For large files, operations can take several minutes to complete. Subsequent reads of the object will return one of messages shown in the first table, to allow for tracking of the progress of the move operation.
atFilev2Flash_1	{ atFilev2Operation 10 }	Represents the Flash operation device object
atFilev2Card_2	{ atFilev2Operation 11 }	Represents the Card operation device object
atFilev2Nvs_3	{ atFilev2Operation 12 }	Represents the NVS operation device object
atFilev2Tftp_4	{ atFilev2Operation 13 }	Represents the TFTP operation device object

Table 89-22: Objects defined in AT-FILEv2-MIB(cont.)

Object(cont.)	Object Identifier	Description
atFilev2TftpIPAddr	{ atFilev2Tftp_4 1 }	The IP address of the TFTP server that is to be used for the file copy process. This IP Address needs to be reachable from the device, or the file copy will fail.
atFilev2SDcardTable	{ atFilev2 4 }	The SD Card table, containing information related to SD Cards. Indexed by: ■ atFilev2SDcardStackMemberId
atFilev2SDcardEntry	{ atFilev2SDcardTable 1 }	Data pertaining to an SD Card instance.
atFilev2SDcardStackMemberId	{ atFilev2SDcardEntry 1 }	The index of the stack member hosting this SD Card.
atFilev2SDcardPresence	{ atFilev2SDcardEntry 2 }	This object indicates whether or not an SD Card is inserted into a slot. Possible values are: ■ notPresent (1) ■ present (2)
atFilev2InfoTable	{ atFilev2 5 }	A list of all files, including pathnames, that are present on the device. Hidden system files are not displayed.
atFilev2InfoEntry	{ atFilev2InfoTable 1 }	An entry in the list of files, containing information about a single file.
atFilev2InfoFilepath	{ atFilev2InfoEntry 1 }	The full path and name of the file. Files are sorted in alphabetical order and any filepath that is longer than 112 characters will not be displayed due to SNMP Object Identifier length limitations.
atFilev2InfoFileSize	{ atFilev2InfoEntry 2 }	The size of the file in bytes.
atFilev2InfoFileCreationTime	{ atFilev2InfoEntry 3 }	File creation time in the form <MMM DD YYYY HH:MM:SS>. For example, Sep 7 2008 06:07:54.
atFilev2InfoFileIsDirectory	{ atFilev2InfoEntry 4 }	This object will return the value TRUE if the entry is a directory, or FALSE if it is not.
atFilev2InfoFileIsReadable	{ atFilev2InfoEntry 5 }	This object will return the value TRUE if the file is readable, or FALSE if it is not.
atFilev2InfoFileIsWriteable	{ atFilev2InfoEntry 6 }	This object will return the value TRUE if the file is writeable, or FALSE if it is not.
atFilev2InfoFileIsExecutable	{ atFilev2InfoEntry 7 }	This object will return the value TRUE if the file is executable, or FALSE if it is not.

AT-LOG-MIB

The AT Log MIB contains objects for listing log entries from the buffered and permanent logs (Table 89-23). The objects reside in the module log { modules 601 }, organized in the following groups:

- Log Table - objects containing the information from log messages issued by the system, ordered from oldest to newest entry
- Log Options - contains objects used to set up the log options configuration

Table 89-23: Objects defined in AT-LOG-MIB

Object	Object Identifier	Description
log	{ modules 601 }	MIB containing objects for listing log entries from the buffered and permanent logs.
logTable	{ log 1 }	A list of log entries from the source specified in the 'logSource' object. The list is ordered from oldest entry to newest entry. Indexed by: ■ logIndex
logEntry	{ logTable 1 }	Information about a single log entry, from the source specified in the 'logSource' object.
logIndex	{ logEntry 1 }	An index integer. This index is not directly tied to any specific log entry. Over time, the log will grow larger and eventually older entries will be removed from the log.
logDate	{ logEntry 2 }	The date of the log entry. Data resides in the format octet string, in the form YYYY MMM DD, e.g. 2008 Oct 9.
logTime	{ logEntry 3 }	The time of the log entry. Data resides in the format octet string, in the form HH:MM:SS, e.g. 07:15:04.
logFacility	{ logEntry 4 }	The syslog facility that generated the log entry, in the format octet string. See the reference manual for more information.
logSeverity	{ logEntry 5 }	The severity level of the log entry, in the format octet string. Severities are given below: ■ emerg Emergency, system is unusable ■ alert Action must be taken immediately ■ crit Critical conditions ■ errr Error conditions ■ warning Warning conditions ■ notice Normal, but significant, conditions ■ info Informational messages ■ debug Debug-level messages
logProgram	{ logEntry 6 }	The program that generated the log entry, in the format octet string. See the reference manual for more information.
logMessage	{ logEntry 7 }	The message of thew log entry, in the format octet string.
logOptions	{ log 2 }	Contains objects used to set up the required log options configuration.

Table 89-23: Objects defined in AT-LOG-MIB(cont.)

Object	Object Identifier	Description
logSource	{ logOptions 1 }	An integer indicating the source from which the log entries are retrieved. The valid values are: ■ 1 - Buffered log (default) ■ 2 - Permanent log. This information is used when retrieving the logTable objects, and also specifies the log to be cleared when the 'clearLog' object is set.
logAll	{ logOptions 2 }	An integer indicating whether to display all log entries in the logTable objects, or not. The valid values are: ■ 0 - to display only the most recent log messages. This is the default ■ 1 - to show all available log entries. Note: Choosing to display all log entries may result in delays of several seconds when accessing the logTable objects.
clearLog	{ logOptions 3 }	An integer indicating whether to clear the log that is specified by the 'logSource' object. Valid values are: ■ 0 - do not clear log ■ 1 - clear log

AT-IP-MIB

This MIB contains objects for Allied Telesis specific IP address management (Table 89-24). The objects reside in the module atIpMib { modules 602 }.

Table 89-24: Objects defined in AT-IP-MIB

Object	Object Identifier	Description
atIpMib	{ modules 602 }	MIB containing objects for IP addressing management.
AtIpAddressAssignmentType	Textual Convention	Object containing conditional coded values for the IP address assignment type being applied to the interface, referred to by objects in this MIB. The possible values and explanation are: ■ notSet (0) - indicates that the IP address assignment type has not yet been configured. This value can only ever be read. ■ primary (1) - indicates that the address is a primary IP address; only one primary address is allowed per interface. ■ secondary (2) - indicates that the address is a secondary IP address; any number of secondary IP addresses may be applied
AtIpAddressTable	{ atIpMib 1 }	A table containing mappings between primary or secondary IP addresses, and the interfaces they are assigned to. Indexed by: ■ atIpAddressAddrType ■ atIpAddressAddr
AtIpAddressEntry	{ AtIpAddressTable 1 }	Information about the address mapping for a particular interface.
atIpAddressAddrType	{ AtIpAddressEntry 1 }	An indication of the IP version of 'atIpAddressAddr'
atIpAddressAddr	{ AtIpAddressEntry 2 }	The IP address to which this entry's addressing information pertains. The address type of this object is specified in object 'atIpAddressAddrType'.
atIpAddressPrefixLen	{ AtIpAddressEntry 3 }	An integer, specifying the prefix length of the IP address represented by this entry.
atIpAddressLabel	{ AtIpAddressEntry 4 }	The name assigned to the IP address represented by this entry.
atIpAddressIfIndex	{ AtIpAddressEntry 5 }	The index value that uniquely identifies the interface to which this entry is applicable. The interface identified by a particular value of this index corresponds to the interface identified by the same value of the IF-MIB's ifIndex.
atIpAddressAssignmentType	{ AtIpAddressEntry 6 }	The IP address assignment type for this entry (primary or secondary), as described in the Textual Convention 'AtIpAddressAssignmentType'.

Table 89-24: Objects defined in AT-IP-MIB(cont.)

Object	Object Identifier	Description
atIpAddressRowStatus	{ AtIpAddressEntry 7 }	The current status of the IP address entry. The following values may be returned when reading this object: ■ active (1) The IP address is currently mapped to an interface and is valid. ■ notReady (3) The IP address is currently partially configured and is not mapped to an interface. The following values may be written to this object: ■ active (1) An attempt will be made to map the IP address to the configured interface. ■ createAndWait (5) An attempt will be made to create a new IP address entry. ■ destroy (6) The IP address setting will be removed from the device. An entry cannot be made active until its atIpAddressPrefixLen, atIpAddressIfIndex and atIpAddressAssignmentType objects have been set to valid values.

Public MIBs

The following table lists the public MIBs supported by the AlliedWare Plus™ Operating System. In general, all objects are supported except where the relevant protocol or feature is either not supported or not applicable to the device. Any variations from the standard are listed.

Table 89-25: Public MIBs Supported by AlliedWare Plus™

MIB Name	Reference / Implementation
IANAifType-MIB	www.iana.org/assignments/ianaiftype-mib, IANAifType textual convention.
RFC1155-SMI	RFC 1155, *Structure and Identification of Management Information for TCP/IP-based Internets.*
-	RFC 1212, *Concise MIB Definitions.*
RFC1213-MIB	See IP-MIB.
-	RFC 1215, *A Convention for Defining Traps for use with the SNMP.*
-	RFC 1239, *Reassignment of Experimental MIBs to Standard MIBs.*
IP-MIB	The IP MIB tree encompasses IP-MIB, RFC1213-MIB and IP-FORWARD-MIB definitions. The following documents define the components: ■ RFC 1213, *Management Information Base for Network Management of TCP/IP-based internets: MIB-II* ■ RFC 4292, *IP Forwarding Table MIB* ■ RFC 4293, *Management Information Base for the Internet Protocol (IP)* The following objects are supported: ■ ipForwarding ■ ipDefaultTTL ■ All ipAddrTable objects except ipAdEntReasmMaxSize ■ All ipNetToPhysicalTable objects except ipNetToPhysicalRowStatus (all read-only) ■ ipCidrRouteNumber ■ All ipCidrRouteTable objects except ipCidrRouteTos All other objects in these MIBs are not supported. Note that an Enterprise version of ipAddressTable objects is provided by atIpAddressTable in AT-IP-MIB. This provides equivalent functionality along with support for primary and secondary IP addresses.
TCP-MIB	RFC 2012, *SNMPv2 Management Information Base for the Transmission Control Protocol using SMIv2.*
UDP-MIB	RFC 2013, *SNMPv2 Management Information Base for the User Datagram Protocol using SMIv2.*
IP-FORWARD-MIB	See IP-MIB.

    Configure Authentication for Voice VLAN 90.18

Introduction

This chapter describes the Link Layer Discovery Protocol (LLDP), LLDP for Media Endpoint Devices (LLDP-MED) and Voice VLAN, and general configuration information for these.

LLDP is designed to be managed with the Simple Network Management Protocol (SNMP), and SNMP-based Network Management Systems (NMS). LLDP can be configured, and the information it provides can be accessed, using either the command line interface or SNMP.

- For detailed descriptions of the commands used to configure LLDP and LLDP-MED, see Chapter 91, LLDP Commands.
- For Voice VLAN commands, see Chapter 17, VLAN Commands.
- For information about the LLDP and LLDP-MED MIBs, see "Public MIBs" on page 89.66.

Link Layer Discovery Protocol

Link Layer Discovery Protocol (LLDP) is a Layer 2 protocol defined by the *IEEE Standard 802.1AB-2005*. This switch supports LLDP as specified in this standard, including *Annex F* and *Annex G*.

LLDP enables Ethernet network devices, such as switches and routers, to transmit and/or receive device-related information to or from directly connected devices on the network, and to store such information learned about other devices. The data sent and received by LLDP is useful for many reasons. The switch can discover neighbors—other devices directly connected to it. Devices can use LLDP to advertise some parts of their Layer 2 configuration to their neighbors, enabling some kinds of misconfiguration to be more easily detected and corrected.

LLDP is a link level ("one hop") protocol; LLDP information can only be sent to and received from devices that are directly connected to each other, or connected via a hub or repeater. Advertised information is not forwarded on to other devices on the network.

The information transmitted in LLDP advertisements flows in one direction only, from one device to its neighbors, and the communication ends there. Transmitted advertisements do not solicit responses, and received advertisements do not solicit acknowledgement.

LLDP operates over physical ports (Layer 2) only. For example, it can be configured on switch ports that belong to static or dynamic aggregated links (channel groups), but not on the aggregated links themselves; and on switch ports that belong to VLANs, but not on the VLANs themselves.

LLDP provides a way for the switch to:

- transmit information about itself to neighbors
- receive device information from neighbors
- store and manage information in an LLDP MIB

Each port can be configured to transmit local information, receive neighbor information, or both.

LLDP defines:

- a set of common advertisements ("LLDP Advertisements" on page 90.4)
- a protocol for transmitting and receiving advertisements ("Transmission and Reception" on page 90.8)
- a method for storing the information that is contained within received advertisements ("Storing LLDP Information" on page 90.10)

Interactions

LLDP has the following interactions with other switch features:

- Spanning tree

  Ports blocked by a spanning tree protocol can still transmit and receive LLDP advertisements.

- 802.1x

  Ports blocked by 802.1x port authorization cannot transmit or receive LLDP advertisements. If LLDP has stored information for a neighbor on the port before it was blocked, this information will eventually time out and be discarded.

- VLAN tagging

  LLDP packets are untagged; they do not contain 802.1Q header information with VLAN identifier and priority tagging.

- Virtual Chassis Stacking (VCStack) resiliency link

  When a port is configured as a VCStack resiliency link port, LLDP does not operate on the port; LLDP neither transmits nor receives advertisements, and any LLDP configuration and data stored for the port, including counters, is discarded.

- Mirror ports

  LLDP does not operate on mirror analyzer ports.

LLDP-MED

LLDP for Media Endpoint Devices (LLDP-MED), is an extension of LLDP used between LAN network connectivity devices, such as this switch, and the media endpoint devices connected to them, such as IP phones. LLDP-MED is specified in *ANSI/TIA-1057-2006*. Of the application types specified in *ANSI/TIA-1057-2006*, the switch supports Application Type 1: Voice.

LLDP-MED uses the LLDP advertisement, transmission and storage mechanisms, but transmits, receives, and stores data specifically related to managing the voice endpoint devices. This includes information about network policy, location, hardware configuration, and, for Power over Ethernet-capable devices, power management.

Voice VLAN

Many IP phones (or other IP voice devices) have two interfaces: one to connect to the network and another that allows a computer or similar device to connect to the network via the IP phone. It is often desirable to treat the voice and data traffic separately so that appropriate Quality of Service (QoS) policies can be applied to each. The Voice VLAN feature uses LLDP-MED to convey configuration information (such as VLAN ID and User Priority tagging, and DiffServ Code Point (DSCP)—"Differentiated Services Architecture" on page 60.4) for the voice traffic to the IP phone. In response, the IP phone sends voice traffic according to this

configuration. The data traffic coming through the IP phone from the PC is sent with the default configuration, typically untagged with normal priority.

LLDP Advertisements

LLDP transmits advertisements as packets called LLDP Data Units (LLDPDUs). An LLDPDU consists of a set of Type-Length-Value elements (TLV), each of which contains a particular type of information about the device or port transmitting it.

Type-Length-Value (TLV)

A single LLDPDU contains multiple TLVs. TLVs are short information elements that communicate complex data, such as variable length strings, in a standardized format. Each TLV advertises a single type of information, such as its device ID, type, or management addresses. The following table describes fields in a TLV.

Table 90-1: Fields in a Type Length Value element

Field	Description
Type	Identifies the kind of information. It consists of a 7-bit Type code.
Length	Identifies the length of the information. It consists of a 9-bit value that specifies the number of bytes of data in the Value field.
Value	Contains the actual value of the advertised information. This is a variable length data field.

LLDP sends mandatory TLVs in each advertisement; it can also be configured to send one or more optional TLVs, from the following groups:

- Mandatory Base TLVs, included in all LLDP advertisements. See IEEE 802.1AB-2005.
- Optional Base TLVs, which may be included in any LLDP advertisements. See IEEE 802.1AB-2005.
- IEEE 802.1 Organizationally Specific TLVs (802.1 TLVs). See IEEE 802.1AB-2005 Annex F.
- IEEE 802.3 Organizationally Specific TLVs (802.3 TLVs). See IEEE 802.1AB-2005 Annex G.
- LLDP-MED Organizationally Specific TLVs (LLDP-MED TLVs), included in LLDP-MED advertisements. See ANSI/TIA-1057- 2006.

Mandatory and optional TLVs for LLDP and LLDP-MED advertisements are shown in Table 90-2.

Table 90-2: TLVs in LLDP advertisements

TLV	Description
Mandatory Base TLVs—IEEE 802.1AB-2005	
Chassis ID	Identifies the device's chassis. On this switch, this is the MAC address of the switch or stack.
Port ID	Identifies the port that transmitted the LLDPDU.

Table 90-2: TLVs in LLDP advertisements(cont.)

TLV	Description
Time To Live (TTL)	Indicates the length of time in seconds for which the information received in the LLDPDU remains valid. If the value is greater than zero, the information is stored in the LLDP remote system MIB. If the value is zero, the information previously received is no longer valid, and is removed from the MIB.
End of LLDPDU	Signals that there are no more TLVs in the LLDPDU.
Optional Base TLVs—IEEE 802.1AB-2005	
Port description	A description of the device's port in alpha-numeric format.
System name	The system's assigned name in alpha-numeric format.
System description	A description of the device in alpha-numeric format. This includes information about the device's hardware and operating system.
System capabilities	The device's router and bridge functions, and whether or not these functions are currently enabled.
Management address	The address of the local LLDP agent. This can be used to obtain information related to the local device.
IEEE 802.1 Organizationally Specific TLVs (802.1 TLVs)—IEEE 802.1AB-2005 Annex F	
Port VLAN	VLAN identifier that the local port associates with untagged or priority tagged frames.
Port & Protocol VLANs	Whether Port & Protocol VLAN is supported and enabled on the port, and the list of Port & Protocol VLAN identifiers.
VLAN Names	List of VLAN names that the port is assigned to.
Protocol IDs	List of protocols that are accessible through the port, for instance: ■ 9000 (Loopback) ■ 00 26 42 42 03 00 00 00 (STP) ■ 00 27 42 42 03 00 00 02 (RSTP) ■ 00 69 42 42 03 00 00 03 (MSTP) ■ 888e01 (802.1x) ■ aa aa 03 00 e0 2b 00 bb (EPSR) ■ 88090101 (LACP) ■ 00540000e302 (Loop protection) ■ 0800 (IPv4) ■ 0806 (ARP) ■ 86dd (IPv6)
IEEE 802.3 Organizationally Specific TLVs (802.3 TLVs)—IEEE 802.1AB-2005 Annex G	
MAC/PHY Configuration/Status	The current values of the following for the port: ■ Speed and duplex mode auto-negotiation support ■ Auto-negotiation status ■ PMD (physical media dependent) auto-negotiation advertised capability ■ Operational MAU type This TLV is always included in LLDP-MED advertisements.
Power Via MDI	The power-via-MDI capabilities. On devices that are LLDP-MED and PoE-capable, we recommend using the Extended Power-via-MDI TLV instead of this TLV.
Link Aggregation	Whether the link is capable of being aggregated, whether it is currently in an aggregation and if in an aggregation, the port of the aggregation.

Table 90-2: TLVs in LLDP advertisements(cont.)

TLV	Description
Maximum Frame Size	The maximum supported 802.3 frame size that the sending device is capable of receiving—larger frames will be dropped.
LLDP-MED Organizationally Specific TLVs (LLDP-MED TLVs)—ANSI/TIA-1057- 2006	
LLDP-MED Capabilities	Indicates an LLDP-MED capable device, and advertises which LLDP-MED TLVs are supported and enabled, and the device type. For this switch, the device type is Network Connectivity Device. An advertisement containing this TLV is an LLDP-MED advertisement.
Network Policy	Network policy information configured on the port for connected media endpoint devices. The switch supports Application Type 1: Voice, including the following network policy for connected voice devices to use for voice data: ■ Voice VLAN ID ■ Voice VLAN User Priority tagging ■ Voice VLAN Diffserv Code Point (DSCP)
Location Identification	Location information configured for the port, in one or more of the following formats: ■ Civic address ■ Coordinate-based LCI ■ Emergency Location Identification Number (ELIN) For more information, see "LLDP-MED: Location Identification TLV" on page 90.7.
Extended Power-via-MDI	For PoE-capable devices, this TLV includes: ■ Power Type field: Power Sourcing Entity (PSE). ■ Power Source field: current power source, either Primary Power Source or Backup Power Source. ■ Power Priority field: power priority configured on the port. ■ Power Value field: In TLVs transmitted by a Power Sourcing Equipment (PSE) such as this switch, this advertises the power that the port can supply over a maximum length cable based on its current configuration (that is, it takes into account power losses over the cable). In TLVs received from Powered Device (PD) neighbors, the power value is the power the neighbor requests. Available on devices that are PoE-capable.
Inventory Management TLV Set	Includes the following TLVs, based on the current hardware platform and the software version, identical on every port on the switch: ■ Hardware Revision ■ Firmware Revision ■ Software Revision ■ Serial Number ■ Manufacturer Name ■ Model Name ■ Asset ID On Virtual Chassis Stacking devices, the inventory information is based on the current master.

LLDP-MED: Location Identification TLV

Location information can be configured for each port, and advertised to remote devices, which can then transmit this information in calls; the location associated with voice devices is particularly important for emergency call services. All ports may be configured with the location of the switch, or each port may be configured with the location of the remote voice device connected to it.

The location information for a particular port can be configured using one or more of the following three data formats: coordinate-based, Emergency Location Identification Number (ELIN), and civic address. Up to one location of each type can be assigned to a port.

Location configuration information (LCI) in all configured data formats is transmitted in Location Identification TLVs. When LLDP receives a Location Identification TLV, it updates the remote entry in the LLDP-MED MIB with this information.

Co-ordinate LCI Coordinate-based location data format uses geospatial data, that is, latitude, longitude, and altitude (height or floors), including indications of resolution, with reference to a particular datum: WGS 84, NAD83—North American Vertical Datum of 1988 (NAVD88), or NAD83—Mean Lower Low Water (MLLW). For more information, see *RFC 3825, Dynamic Host Configuration Protocol Option for Coordinate-based Location Configuration Information.*

ELIN LCI Emergency Location Identification Number (ELIN) location data format provides a unique number for each location for Emergency Call Services (ECS). In North America, ELINs are typically 10 digits long; ELINs up to 25 digits are supported.

Civic Address LCI The Civic Address location data format uses common street address format, as described in *RFC4776*.

Transmission and Reception

Table 90-3 describes the LLDP transmission and reception processes. Additional LLDP-MED processes are described in "LLDP-MED Operation" on page 90.9.

Table 90-3: LLDP transmission and reception processes

When ...	And ...	Then ...
LLDP is enabled	Ports are configured to transmit LLDP advertisements	Regular LLDP advertisements are sent via these ports at intervals determined by the transmit interval. Each advertisement contains local information (from the Local Systems MIB) for all the mandatory TLVs and the optional TLVs that the port is configured to send.
	Ports are configured to receive LLDP advertisements	Information received in advertisements via these ports is stored in the Neighbor table (Remote Systems MIB). This information is retained until it is replaced by a more recent advertisement from the same neighbor or it times out (the TTL elapses).
Local information changes	The transmission delay time has elapsed since the last advertisement was transmitted	New advertisements are sent containing the new set of local information.
Neighbor information changes	Notifications are enabled, and the notification interval has elapsed since the last notification was sent	The SNMP notification (trap) lldpRemTablesChange is sent.
LLDP transmission and reception is disabled on a port.	An LLDP command was used to do this	It transmits a final 'shutdown' LLDPDU with a Time-To-Live (TTL) TLV that has a value of "0". This tells any remote neighboring devices to remove the information associated with this switch from their remote systems MIB. Then it stops transmitting and receiving advertisements. The neighbor information remains in the Remote Systems MIB until it times out.
	A shutdown command was used on the port	It makes a best effort to send a shutdown LLDPDU. Then it stops transmitting and receiving advertisements. The neighbor information remains in the Remote Systems MIB until it times out.
	Something else disabled LLDP, such as Virtual Chassis Stacking (VCStack) failover	It does not send a shutdown LLDPDU. It stops transmitting and receiving advertisements. The neighbor information remains in the Remote Systems MIB until it times out.
	It is enabled again	LLDP reinitializes and resumes transmitting and receiving advertisements after the reinitialization interval has elapsed.
The Neighbor table has 1600 neighbors		It discards any further neighbors.
LLDP receives a LLDPDU or TLV with a detectable error		It discards the incorrect TLV.
LLDP receives a TLV it does not recognize	It contains no basic format errors	It stores it for possible later retrieval by network management (in the unrecognized TLV information table lldpRemUnknownTLVTable in the LLDP MIB).

LLDP-MED Operation

When LLDP is enabled, LLDP-MED is enabled by default, and uses the same LLDP transmission and reception process described in Table 90-3. When LLDP receives an advertisement indicating a newly connected LLDP-MED-capable device on a port, it transmits one LLDP-MED advertisement per second via this port, a configurable number of times (the *fast start count*). Thereafter, it sends regular advertisements at the LLDP transmit interval. When the last advertisement for an LLDP-MED-capable device connected to the port times out, it stops sending LLDP-MED advertisements via the port.

If LLDP-MED notifications are enabled for a port, and SNMP traps for LLDP are enabled, LLDP-MED generates a *Topology Change Notification (LLDP-MED lldpXMedTopology ChangeDetected)* when a new LLDP-MED compliant IP telephony device is connected to a port or removed from a port. This notification includes the following information:

- IP Phone Chassis ID and Chassis ID sub-type (IP address)
- LLDP Endpoint Device Class
- Switch Chassis ID (MAC address) and Port ID where the device is attached.

Storing LLDP Information

When an LLDP device receives a valid LLDP advertisement from a neighboring network device, it stores the information in an IEEE-defined Simple Network Management Protocol (SNMP) Management Information Base (MIB).

LLDP stores information in the LLDP MIB defined in Section 12 of the *IEEE Standard 802.1AB-2005*, its extensions defined in *Annex F*, *Annex G*, and ANSI/TIA-1057- 2006, about:

LLDP-EXT-MED-MIB ANSI/TIA-1057- 2006, Section 13.3, LLDP-MED MIB Definition

- Local system information. This is the information that LLDP can transmit in advertisements to its neighbors.
- Remote systems information. This is the data that the device receives in advertisements from its neighbors.
- LLDP configuration. This can be used with SNMP to configure LLDP on the device.
- LLDP statistics. This includes information about LLDP operation on the device, including packet and event counters.

This information can be accessed either via SNMP, or directly using the command line interface.

Local system

Information about your device is called local system information. The LLDP local system MIB maintains this information, which consists of device details, as well as any user-configured information that you have set up for your switch, for example a port description or a management address.

LLDP on this device can store one management address per port, and transmit this in LLDP advertisements. It can store multiple management addresses received from each neighbor.

Remote systems

Information gained from neighboring devices is called remote system information. The LLDP remote systems MIB maintains this information.

The length of time for which neighbor information remains in the LLDP remote systems MIB is determined by the Time-To-Live (TTL) value of received LLDPDUs. When it receives an advertisement from a neighbor, LLDP starts a timer based on the Time To Live (TTL) information in the advertisement. The Time To Live (TTL) information in an advertisement is: TTL=transmit interval x holdtime multiplier. If the TTL elapses, for instance if the neighbor has been removed, LLDP deletes the neighbor's information from the MIB. This ensures that only valid LLDP information is stored.

Whenever a new neighbor is discovered, or an existing neighbor sends an advertisement with new information that differs from the previous advertisement, for example a new or changed TLV, a remote tables change event is activated. If SNMP notifications are enabled, the notification lldpRemTablesChange is sent.

To prevent the remote systems MIB from using large amounts of memory and possibly affecting the operation of your switch, it limits the number of neighbors it stores information for to 1600. If it is storing information from 1600 neighbors, and detects any more neighbors, it is considered to have too many neighbors, and discards advertisements from the rest. There is no per-port limit to the number of neighbors.

SNMP utilities

An SNMP utility can read the Neighbors table MIB (Remote Systems Data in the LLDP MIB) on a device to find out about the LLDP neighbors it is directly connected to on each port. Then it can read the Neighbors table MIB on each of these neighbors to find out about their neighboring LLDP devices, and so on.

Configuring LLDP

You can configure LLDP on the device using either:

- the command line interface. For detailed descriptions of the commands, see Chapter 91, LLDP Commands, or
- SNMP—see Chapter 89, SNMP MIBs.

This section includes the following command line interface configuration procedures:

- "Configure LLDP" on page 90.12— This procedure includes configuration for LLDP between network connectivity devices; it does not include LLDP-MED. If you are configuring LLDP-MED only, use the following procedure instead of this one.
- "Configure LLDP-MED" on page 90.14—This procedure includes the LLDP configuration required to support LLDP-MED, as well as specific LLDP-MED and Voice VLAN configuration.
- "Configure Authentication for Voice VLAN" on page 90.18—This procedure includes 802.1X port authentication configuration including dynamic VLAN assignment to be used with LLDP-MED. Use the previous procedure before using this one.

Because LLDP is often used together with SNMP, consider configuring SNMP before you configure LLDP. LLDP transmits large amounts of data about the network. For security reasons, we recommend configuring SNMP for SNMP version 3 only (for read and write access). Remove all SNMPv1 and SNMPv2 configuration. See Chapter 87, SNMP Introduction, and Chapter 88, SNMP Commands.

Configure LLDP

Use the procedure in Table 90-4 below to configure LLDP.

Some optional TLVs send information that can be configured by other commands. If LLDP will be configured to send these TLVs, consider whether to configure the corresponding parameters first.

- Port Description. See the description (interface) command on page 11.2.
- System Name. See the hostname command on page 8.18.

Table 90-4: Configuration procedure for LLDP

Enable LLDP		
1.	`awplus#configure terminal`	Enter Configuration mode.
2.	`awplus(config)#lldp run`	Enable LLDP.
Configure ports for LLDP		
Configure each port to determine whether and which LLDP messages are transmitted and received. If all the ports running LLDP require the same configuration, configure them all together. Otherwise repeat these commands for each port or group of ports that requires a particular configuration.		
3.	`awplus(config)# interface <port-list>`	Enter Interface Configuration mode for the switch ports.
4.	`awplus(config-if)#lldp tlv-select {[<tlv>]...}` `awplus(config-if)#lldp tlv-select all`	By default, the mandatory TLVs are included in LLDP messages. Enable the transmission of one or more optional TLVs through these port as required.
5.	`awplus(config-if)#exit`	Return to Global Configuration mode.
6.	`awplus(config)#interface <port-list>`	By default, transmission and reception of LLDP advertisements is enabled on all ports. Enter Interface Configuration mode for any switch ports that should have transmission or reception disabled.
7.	`awplus(config-if)#no lldp {[transmit] [receive]}`	Disable transmission and/or reception as required.
8.	`awplus(config-if)#exit`	Return to Global Configuration mode.
9.	`awplus(config)#exit`	Return to Privileged Exec mode.
Check LLDP configuration		

10.	`awplus#show lldp`
	`awplus#show lldp interface [<port-list>]`
	`awplus#show lldp local-info [base] [dot1] [dot3] [med] [interface <port-list>]`
	`awplus#show running-config lldp`
		Review the LLDP configuration.

Monitor LLDP		

11.	`awplus#show lldp neighbors`
	`awplus#show lldp neighbors detail`
	`awplus#show lldp statistics`
	`awplus#show lldp statistics interface [<port-list>]`
		Monitor LLDP operations and display neighbor information as required.

Table 90-4: Configuration procedure for LLDP**(cont.)**

Advanced LLDP configuration		
The configuration procedure above and the defaults for other settings suit most networks. Use the following commands for fine tuning if necessary. Timer intervals should be long enough not to create unnecessarily high numbers of advertisements when there are topology changes. However, be aware that if the intervals are long, a neighbor's information can continue to be stored after its information has changed, or after it is disconnected.		
12.	`awplus#configure terminal`	Enter Configuration mode.
13.	`awplus(config)#interface <port-list>`	Enter Interface Configuration mode for the switch ports.
14.	`awplus(config-if)#lldp management-address <ipaddr>`	Override the default LLDP management address advertised through this port if required. This must be an IPv4 address that is already configured on the device. To see the management address that will be advertised, use the show lldp local-info command on page 91.39.
15.	`awplus(config-if)#lldp notifications`	By default, SNMP notifications are not transmitted. Enable them for these ports if required. (SNMP LLDP traps (notifications) must also be enabled.)
16.	`awplus(config-if)#exit`	Return to Global Configuration mode.
17.	`awplus(config)#lldp timer <5-32768>`	The transmit interval determines how often regular LLDP transmits advertisements from each port. The transmit interval must be at least four times the transmission delay. Default: 30 seconds
18.	`awplus(config)#lldp notification-interval <5-3600>`	The notification interval determines the minimum interval between sending SNMP notifications (traps). Default: 5 seconds
19.	`awplus(config)#lldp tx-delay <1-8192>`	A series of successive changes over a short period of time can trigger the agent to send a large number of LLDPDUs. To prevent this, there is a transmission delay timer. This establishes a minimum length of time that must elapse between successive LLDP transmissions. The transmission delay cannot be greater than a quarter of the transmit interval. Default: 2 seconds
20.	`awplus(config)#lldp reinit <1-10>`	Reinitialization delay timer determines the minimum time after disabling LLDP on a port before it can reinitialize. Default: 2 seconds
21.	`awplus(config)#lldp holdtime-multiplier <2-10>`	The transmit interval is multiplied by the holdtime multiplier to give the Time To Live (TTL) value that is advertised to neighbors. Default: 4
22.	`awplus(config)#exit`	Return to Privileged Exec mode.
Clear data		
If necessary, you can clear either neighbor information or LLDP statistics for particular ports or all ports.		
23.	`awplus#clear lldp table [interface <port-list>]`	Clear the information from the table of neighbor information.
24.	`awplus#clear lldp statistics [interface <port-list>]`	Clear LLDP statistics (packet and event counters).

Configure LLDP-MED

Use the procedure in Table 90-5 to configure LLDP-MED and Voice VLAN for voice devices connected to the switch.

Consider whether you also need to configure:

- Simple Network Management Protocol (Chapter 88, SNMP Commands)
- 802.1X port authentication (Chapter 63, 802.1X Commands, Chapter 65, Authentication Commands, Chapter 67, AAA Commands)
- RADIUS server (Chapter 73, Local RADIUS Server Commands, or Chapter 69, RADIUS Commands)
- Quality of Service (Chapter 61, QoS Commands)
- Access Control Lists (Chapter 56, IPv4 Hardware Access Control List (ACL) Commands and Chapter 57, IPv4 Software Access Control List (ACL) Commands)

In most cases, configuring LLDP-MED using SNMP or using the CLI command line interface (CLI) described in Chapter 91, LLDP Commands has the same effect. However, the effect of configuring location information using SNMP differs from the CLI. When location information is assigned to a port by SNMP and a matching location is not found on the device, then a new location is automatically created and assigned to the specified port. If the location is unset by SNMP later, then the location is removed to prevent accumulating SNMP-set location information. However, if the location is being used for other ports, the automatically created location is not removed until no ports use it. Once it is modified or assigned to other ports by CLI commands, the location remains even after no ports use the location.

Table 90-5: Configuration procedure for Voice VLAN and LLDP-MED

Configure a Voice VLAN		
Create a VLAN for voice data from voice endpoint devices connected to ports on the switch. Specify the network policy for voice data in this voice VLAN. LLDP-MED sends the network policy to voice devices connected to these ports. The voice devices use this network policy to determine the VLAN, priority and DSCP tagging of voice data it transmits.		
1.	`awplus# configure terminal`	Enter Global Configuration mode.
2.	`awplus(config)# vlan database`	Enter VLAN Database Configuration mode.
3.	`awplus(config-vlan)# vlan <vid> [name <vlan-name>] [state {enable|disable}]`	Create a VLAN to be used for the voice data to and from voice devices connected to the switch. By default, the new VLAN is enabled.
4.	`awplus(config-vlan)# exit`	Return to global configuration mode.
5.	`awplus(config)# interface <port-list>`	Enter interface configuration mode for the ports to be configured with the same network policy. This may be all the switch ports with voice devices connected to them, or a subset if the network policy will differ between ports.
6.	`awplus(config-if)# switchport voice vlan [<vid>|dot1p|dynamic|untagged]`	Specify the VLAN tagging to be used for voice data on these ports. Use the dynamic option if the VLAN tagging will be allocated dynamically by a RADIUS server. To configure authentication and dynamic VLAN allocation using the local RADIUS server, see the procedure in Table 90-6 on page 90.18. Default: none.

Table 90-5: Configuration procedure for Voice VLAN and LLDP-MED(cont.)

7.	`awplus(config-if)#` switchport voice vlan priority <0-7>	Specify the priority-tagging that voice endpoint devices should put into their data packets. Default: 5.
8.	`awplus(config-if)#` switchport voice dscp <0-63>	Specify the DSCP value that voice endpoint devices should put into their data packets. Default: 0.
9.	`awplus(config-if)#` exit	Return to global configuration mode.
Enable LLDP		
10.	`awplus(config)#` lldp run	Enable LLDP on the switch. Default: LLDP is disabled.
11.	`awplus(config)#` interface *<port-list>*	Enter interface configuration mode for the switch ports LLDP is NOT to run on.
12.	`awplus(config-if)#` no lldp {[transmit] [receive]}	Disable transmission or reception on these ports as required. Default: transmit and receive enabled.
13.	`awplus(config-if)#` exit	Return to global configuration mode.
Configure LLDP-MED location information		
Create civic address, coordinate, and/or ELIN locations, and assign them to switch ports.		
14.	`awplus(config)#` location civic-location identifier <civic-loc-id>	Specify a civic location ID, and enter configuration mode for this identifier.
15.	`awplus(config-civic)#` country <country> `awplus(config-civic)#` city <city> `awplus(config-civic)#` primary-road-name <primary-road-name> `awplus(config-civic)#` street-suffix <street-suffix> `awplus(config-civic)#` house-number <house-number> `awplus(config-civic)#` *<other-civic-location-parameters …>*	Specify the civic address location information for the civic address location ID. You must specify a country first, using the upper-case two-letter country code, and then at least one more parameter. For the full set of parameters you can use to specify civic address location, see the location civic-location configuration command on page 91.22.
16.	`awplus(config-civic)#` exit	Return to global configuration mode.
17.	`awplus(config)#` location coord-location identifier <coord-loc-id>	Specify a coordinate location identifier, and enter configuration mode for this identifier.
18.	`awplus(config-coord)#` latitude <latitude> `awplus(config-coord)#` lat-resolution <lat-resolution> `awplus(config-coord)#` longitude <longitude> `awplus(config-coord)#` long-resolution <long-resolution> `awplus(config-coord)#` altitude <altitude> {meters|floor} `awplus(config-coord)#` alt-resolution <alt-resolution> `awplus(config-coord)#` datum {wgs84|nad83-navd|nad83-mllw}	Specify the coordinate location for the coordinate location identifier.
19.	`awplus(config-coord)#` exit	Return to global configuration mode.

Table 90-5: Configuration procedure for Voice VLAN and LLDP-MED(cont.)

20.	`awplus(config)#` location elin-location <elin> identifier <elin-loc-id>	Specify an ELIN location identifier, and the ELIN for this identifier.
21.	`awplus(config)#` interface *<port-list>*	Enter interface configuration mode for one or more switch ports which require the same location information.
22.	`awplus(config-if)#` location civic-location-id <civic-loc-id> `awplus(config-if)#` location coord-location-id <coord-loc-id> `awplus(config-if)#` location elin-location-id <elin-loc-id>	Assign the civic, coordinate, and/or ELIN location identifier to these ports. LLDP-MED will send the location information associated with a port to the voice endpoint device attached to it.
23.	`awplus(config-if)#` exit	Return to global configuration mode.
24.	`awplus(config)#` exit	Return to Privileged Exec mode.
Review the LLDP configuration		
25.	`awplus#` show lldp	Check general LLDP configuration settings.
26.	`awplus#` show lldp interface [<port-list>]	Check LLDP configuration for ports.
27.	`awplus#` show lldp local-info [base] [dot1] [dot3] [med] [interface <port-list>]	Check the information that may be transmitted in LLDP advertisements from ports.
28.	`awplus#` show location {civic-location|coord-location|elin-location} `awplus#` show location {civic-location|coord-location|elin-location} identifier {<civic-loc-id>|<coord-loc-id>|<elin-loc-id>} `awplus#` show location {civic-location|coord-location|elin-location} interface <port-list>	Check the location information.
29.	`awplus#` show running-config lldp	If you want to display all the LLDP configuration, use this command.
Monitor LLDP-MED		
30.	`awplus#` show lldp neighbors [interface <port-list>] `awplus#` show lldp neighbors detail [base] [dot1] [dot3] [med] [interface <port-list>] `awplus#` show lldp statistics `awplus#` show lldp statistics interface [<port-list>]	Monitor LLDP operation.
Advanced configuration		
The configuration procedure above and the defaults for other settings suit most networks. Use the following commands for fine tuning if necessary. For information about other advanced configuration for LLDP, including LLDP timers, see Table 90-4.		
31.	`awplus#`configure terminal	Enter Global Configuration mode.
32.	`awplus(config)#` lldp faststart-count <1-10>	By default, when LLDP-MED detects an LLDP-MED capable device on a port, it sends 3 advertisements at 1s intervals. Change the fast start count if required. Default: fast start count is 3

Table 90-5: Configuration procedure for Voice VLAN and LLDP-MED(cont.)

33.	`awplus(config)#` lldp non-strict-med-tlv-order-check	By default non-strict order checking for LLDP-MED advertisements is disabled. That is, strict order checking is applied to LLDP-MED advertisements, and LLDP-MED TLVs in non-standard order are discarded. If you require LLDP-MED advertisements with non-standard TLV order to be received and stored, enable non-strict order checking.
34.	`awplus(config)#` interface *<port-list>*	Enter interface configuration mode for switch ports which will have the same advanced configuration.
35.	`awplus(config-if)#` lldp management-address <ipaddr>	Override the default LLDP management address advertised through this port if required. This must be an IPv4 address that is already configured on the device. To see the management address that will be advertised, use the show lldp local-info command on page 91.39.
36.	`awplus(config-if)#` lldp med-notifications	By default, SNMP notifications are not transmitted. Enable LLDP-MED Topology Change Detected notifications for these ports if required. (SNMP LLDP traps (notifications) must also be enabled.) Default: LLDP-MED notifications disabled
37.	`awplus(config-if)#` lldp tlv-select {[<tlv>]...}	Enable the transmission of one or more optional LLDP TLVs in LLDP-MED advertisements through this port as required. The mac-phy-config TLV is transmitted in LLDP-MED advertisements whether or not it is enabled by this command. Default: all mandatory TLVs are enabled.
38.	`awplus(config-if)#` lldp med-tlv-select {[capabilities] [network-policy] [location] [inventory-management]} `awplus(config-if)#` lldp med-tlv-select all `awplus(config-if)#` no lldp med-tlv-select {[capabilities] [network-policy] [location] [inventory-management]} `awplus(config-if)#` no lldp med-tlv-select all	Enable or disable the transmission of optional LLDP-MED TLVs in LLDP-MED advertisements through these ports as required. Default: capabilities, network-policy, location, power-management are enabled.
39.	`awplus(config-if)#` exit	Return to global configuration mode.
40.	`awplus(config)#` exit	Return to privileged exec mode.

Clear data

If necessary, you can clear either neighbor information or LLDP statistics for particular ports or all ports.

41.	`awplus#` clear lldp table [interface <port-list>]	Clear the information from the table of neighbor information.
42.	`awplus#` clear lldp statistics [interface <port-list>]	Clear LLDP statistics (packet and event counters).

Configure Authentication for Voice VLAN

Use the following procedure with LLDP-MED and Voice VLAN to configure 802.1X port authentication and dynamic VLAN assignment using the local RADIUS server on the switch to which the voice endpoint devices are connected.

This procedure assumes that you have already:

- configured Voice VLAN and LLDP-MED using the procedure in Table 90-5 on page 90.14
- set switchport voice vlan to dynamic in the above procedure

This procedure configures the local RADIUS server. If your configuration uses one or more remote RADIUS servers instead, set the IP addresses of the remote RADIUS servers using the radius-server host command (Step 3 on page 18), and skip all the steps that configure the local RADIUS server (Step 3 on page 18 to Step 14 on page 19).

Table 90-6: Configuration procedure for Voice VLAN with RADIUS authentication and dynamic VLAN

Configure the IP address of the RADIUS host.		
1.	`awplus#configure terminal`	Enter Global Configuration mode.
2.	`awplus(config)#radius-server host` 127.0.0.1 key *<key-string>*	Configure the IP address for the RADIUS server to be the local loopback interface address, so that RADIUS requests are sent to the local RADIUS server. Set the key that Network Access Servers (NAS) will need to use to get access to this RADIUS server. RADIUS server hosts configured using this command are included in the default RADIUS server group.
Enable the local RADIUS server.		
3.	`awplus(config)# radius-server local`	Enter RADIUS Server Configuration mode.
4.	`awplus(config-radsrv)# server enable`	Enable the local RADIUS server.
5.	`awplus(config-radsrv)# nas` 127.0.0.1 key *<key-string>*	Set the switch as a client device (Network Access Server), to allow it to send authentication requests to the local RADIUS server. Use the same local loopback interface IP address and key as in the radius-server host command used in Step 2 on page 18.
Configure a local RADIUS user group for connected PCs.		
6.	`awplus(config-radsrv)# group <user-group-name>`	Create a local RADIUS server user group for PCs connected to the switch, and enter RADIUS Server Group Configuration mode.
7.	`awplus(config-radsrv-group)# vlan {<vid>|<vlan-name>}`	Set the VLAN ID for the user group. This will assign the untagged VLAN ID to authenticated ports for PCs connected to the switch. To create multiple user groups for PCs with different VLANs, repeat these two steps.
8.	`awplus(config-radsrv-group)#exit`	Return to RADIUS Server Configuration mode.
Configure a local RADIUS user group for connected phones.		
9.	`awplus(config-radsrv)# group <user-group-name>`	Create a new local RADIUS server user group for phones connected to the switch, and enter RADIUS Server Group Configuration mode.

Table 90-6: Configuration procedure for Voice VLAN with RADIUS authentication and dynamic VLAN(cont.)

10.	`awplus(config-radsrv-group)#` vlan {<vid>|<vlan-name>}	Configure the local RADIUS user group for connected phones to use the same VLAN as the PCs in Step 7, so that the phones have access to the same untagged VLAN as the PCs.
11.	`awplus(config-radsrv-group)#` egress-vlan-id <*vid*> tagged	Set the Egress-VLAN ID attribute for the user group, and set it to send tagged frames. This will assign the tagged VLAN ID to authenticated ports for phones connected to the switch. To create multiple user groups for phones with different VLANs, repeat these two steps.
12.	`awplus(config-radsrv-group)#` exit	Return to RADIUS Server Configuration mode.
Add users to the local RADIUS server.		
13.	`awplus(config-radsrv)#` user <radius-user-name> password <user-password> group <user-group>	Add RADIUS user names and passwords to the local RADIUS server for authenticating PCs and phones. Assign the corresponding RADIUS server user groups configured in Step 6 and Step 9. See the user (RADIUS server) command on page 73.36.
14.	`awplus(config-radsrv)#` exit	Return to Global Configuration mode.
Create VLANs.		
15.	`awplus(config)#` vlan database	Enter VLAN Database Configuration mode.
16.	`awplus(config-vlan)#` vlan <*vid-range*>	Create the VLANs corresponding to the VLAN IDs that will be allocated to the authenticated ports, as configured in Step 7, Step 10, and Step 11.
17.	`awplus(config-vlan)#` exit	Return to Global Configuration mode.
Configure 802.1X port authentication.		
18.	`awplus(config)#` aaa authentication dot1x default group radius	Enable 802.1X port authentication and set it to use the default group of RADIUS servers that contains all RADIUS server hosts configured using the radius-server host command—in this procedure, the default group consists of the local RADIUS server.
19.	`awplus(config)#` interface <*port-list*>	Enter interface configuration mode for the ports that have users (PCs and phones) connected to them.
20.	`awplus(config-if)#` dot1x port-control auto	Enable 802.1X for port authentication on these ports.
21.	`awplus(config-if)#` auth host-mode multi-supplicant	Configure the ports to use multi-supplicant mode for authentication, so that the phone and PC can be dynamically allocated to different VLANs.
22.	`awplus(config-if)#` auth dynamic-vlan-creation	Configure the ports to accept dynamic VLAN allocation. In this procedure, the RADIUS server user groups for both the PCs and the phones use the same VLAN (Step 7 and Step 10), so the default rule (deny) allows them both the access they need to the port VLAN. For other options, see the auth dynamic-vlan-creation command on page 65.7. Default: deny differently assigned VLAN IDs.
23.	`awplus(config-if)#` exit	Return to Global Configuration mode.
24.	`awplus(config)#` exit	Return to Privileged Exec mode.

Table 90-6: Configuration procedure for Voice VLAN with RADIUS authentication and dynamic VLAN(cont.)

Review the authentication configuration.		
25.	awplus# show radius local-server group [<user-group-name>] awplus# show radius local-server nas [<ip-address>] awplus# show radius local-server user [<user-name>]	Check the local RADIUS server configuration.
26.	awplus# show vlan {all|brief|dynamic|static|<1-4094>}	Check the VLAN configuration.
27.	awplus# show dot1x [all]	Check the 802.1X authentication configuration.

Introduction

LLDP and LLDP-MED can be configured using the commands in this chapter, or by using SNMP with the LLDP-MIB and LLDP-EXT-DOT1-MIB ("Public MIBs" on page 89.66). The Voice VLAN feature can be configured using commands in Chapter 17, VLAN Commands. For more information about LLDP, see Chapter 90, LLDP Introduction and Configuration.

LLDP can transmit a lot of data about the network. Typically, the network information gathered using LLDP is transferred to a Network Management System by SNMP. For security reasons, we recommend using SNMPv3 for this purpose (Chapter 87, SNMP Introduction, Chapter 88, SNMP Commands).

LLDP operates over physical ports only. For example, it can be configured on switch ports that belong to static or dynamic channel groups, but not on the channel groups themselves.

Command List

This chapter contains an alphabetical list of commands used to configure LLDP.

clear lldp statistics

This command clears all LLDP statistics (packet and event counters) associated with specified ports. If no port list is supplied, LLDP statistics for all ports are cleared.

Syntax `clear lldp statistics [interface <port-list>]`

Parameter	Description
<port-list>	The ports for which the statistics are to be cleared.

Mode Privileged Exec

Examples To clear the LLDP statistics on ports 1.0.1 and 1.0.7, use the command:

```
awplus# clear lldp statistics interface port1.0.1,port1.0.7
```

To clear all LLDP statistics for all ports, use the command:

```
awplus# clear lldp statistics
```

Related Commands show lldp statistics
show lldp statistics interface

clear lldp table

This command clears the table of LLDP information received from neighbors through specified ports. If no port list is supplied, neighbor information is cleared for all ports.

Syntax `clear lldp table [interface <port-list>]`

Parameter	Description
<port-list>	The ports for which the neighbor information table is to be cleared.

Mode Privileged Exec

Examples To clear the table of neighbor information received on ports 1.0.1 and 1.0.7, use the command:

```
awplus# clear lldp table interface port1.0.1,port1.0.7
```

To clear the entire table of neighbor information received through all ports, use the command:

```
awplus# clear lldp table
```

Related Commands show lldp neighbors

debug lldp

This command enables specific LLDP debug for specified ports. When LLDP debugging is enabled, diagnostic messages are entered into the system log. If no port list is supplied, the specified debugging is enabled for all ports.

The no variant of this command disables specific LLDP debug for specified ports. If no port list is supplied, the specified debugging is disabled for all ports.

Syntax

```
debug lldp {[rx][rxpkt][tx][txpkt]} [interface [<port-list>]]
debug lldp operation
no debug lldp {[rx][rxpkt][tx][txpkt]} [interface [<port-list>]]
no debug lldp operation
no debug lldp all
```

Parameter	Description
`rx`	LLDP receive debug.
`rxpkt`	Raw LLDPDUs received in hex format.
`tx`	LLDP transmit debug.
`txpkt`	Raw Tx LLDPDUs transmitted in hex format.
<port-list>	The ports for which debug is to be configured.
`operation`	Debug for LLDP internal operation on the switch.
`all`	Disables all LLDP debugging for all ports.

Default By default no debug is enabled for any ports.

Mode Privileged Exec

Examples To enable debugging of LLDP receive on ports 1.0.1 and 1.0.7, use the command:

```
awplus# debug lldp rx interface port1.0.1,port1.0.7
```

To enable debugging of LLDP transmit with packet dump on all ports, use the command:

```
awplus# debug lldp tx txpkt
```

To disable debugging of LLDP receive on ports 1.0.1 and 1.0.7, use the command:

```
awplus# no debug lldp rx interface port1.0.1,port1.0.7
```

To turn off all LLDP debugging on all ports, use the command:

```
awplus# no debug lldp all
```

Related Commands
show debugging lldp
show running-config lldp
terminal monitor

lldp faststart-count

Use this command to set the fast start count for LLDP-MED. The fast start count determines how many fast start advertisements LLDP sends from a port when it starts sending LLDP-MED advertisements from the port, for instance, when it detects a new LLDP-MED capable device.

The no variant of this command resets the LLDPD-MED fast start count to the default (3).

Syntax

```
lldp faststart-count <1-10>
no lldp faststart-count
```

Parameter	Description
<1-10>	The number of fast start advertisements to send.

Default The default fast start count is 3.

Mode Global Configuration

Examples To set the fast start count to 5, use the command:

```
awplus# configure terminal
awplus(config)# lldp faststart-count 5
```

To reset the fast start count to the default setting (3), use the command:

```
awplus# configure terminal
awplus(config)# no lldp faststart-count
```

Related Commands show lldp

lldp holdtime-multiplier

This command sets the holdtime multiplier value. The transmit interval is multiplied by the holdtime multiplier to give the Time To Live (TTL) value that is advertised to neighbors.

The no variant of this command sets the multiplier back to its default.

Syntax

```
lldp holdtime-multiplier <2-10>
no lldp holdtime-multiplier
```

Parameter	Description
<2-10>	The multiplier factor.

Default The default holdtime multiplier value is 4.

Mode Global Configuration

Usage The Time-To-Live defines the period for which the information advertised to the neighbor is valid. If the Time-To-Live expires before the neighbor receives another update of the information, then the neighbor discards the information from its database.

Examples To set the holdtime multiplier to 2, use the commands:

```
awplus# configure terminal
awplus(config)# lldp holdtime-multiplier 2
```

To set the holdtime multiplier back to its default, use the commands:

```
awplus# configure terminal
awplus(config)# no lldp holdtime-multiplier 2
```

Related Commands show lldp

lldp management-address

This command sets the IPv4 address to be advertised to neighbors (in the Management Address TLV) via the specified ports. This address will override the default address for these ports.

The no variant of this command clears the user-configured management IP address advertised to neighbors via the specified ports. The advertised address reverts to the default.

Syntax

```
lldp management-address <ipaddr>
no lldp management-address
```

Parameter	Description
<ipaddr>	The IPv4 address to be advertised to neighbors, in dotted decimal format. This must be one of the IP addresses already configured on the device.

Default The local loopback interface primary IPv4 address if set, else the primary IPv4 interface address of the lowest numbered VLAN the port belongs to, else the MAC address of the device's baseboard if no VLAN IP addresses are configured for the port.

Mode Interface Configuration

Usage To see the management address that will be advertised, use the show lldp interface command or show lldp local-info command.

Examples To set the management address advertised by ports 1.0.1 and 1.0.7, to be 192.168.1.6, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# lldp management-address 192.168.1.6
```

To clear the user-configured management address advertised by ports 1.0.1 and 1.0.7, and revert to using the default address, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# no lldp management-address
```

Related Commands
show lldp interface
show lldp local-info

lldp med-notifications

Use this command to enable LLDP to send LLDP-MED Topology Change Detected SNMP notifications relating to the specified ports. The switch sends an SNMP event notification when a new LLDP-MED compliant IP Telephony device is connected to or disconnected from a port on the switch.

Use the no variant of this command to disable the sending of LLDP-MED Topology Change Detected notifications relating to the specified ports.

Syntax

```
lldp med-notifications
no lldp med-notifications
```

Default The sending of LLDP-MED notifications is disabled by default.

Mode Interface Configuration

Examples To enable the sending of LLDP-MED Topology Change Detected notifications relating to ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# lldp med-notifications
```

To disable the sending of LLDP-MED notifications relating to ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# no lldp med-notifications
```

Related Commands

lldp notification-interval
lldp notifications
snmp-server enable trap
show lldp interface

lldp med-tlv-select

Use this command to enable LLDP-MED Organizationally Specific TLVs for transmission in LLDP advertisements via the specified ports. The LLDP-MED Capabilities TLV must be enabled before any of the other LLDP-MED Organizationally Specific TLVs are enabled.

Use the no variant of this command to disable the specified LLDP-MED Organizationally Specific TLVs for transmission in LLDP advertisements via these ports. In order to disable the LLDP-MED Capabilities TLV, you must also disable the rest of these TLVs. Disabling all these TLVs disables LLDP-MED advertisements.

Syntax

```
lldp med-tlv-select {[capabilities] [network-policy] [location]
   [inventory-management]}

lldp med-tlv-select all

no lldp med-tlv-select {[capabilities] [network-policy] [location]
   [inventory-management]}

no lldp med-tlv-select all
```

Parameter	Description
`capabilities`	LLDP-MED Capabilities TLV. When this is enabled, the MAC/PHY Configuration/Status TLV from IEEE 802.3 Organizationally Specific TLVs is also automatically included in LLDP-MED advertisements, whether or not it has been explicitly enabled by the lldp tlv-select command.
`network-policy`	Network Policy TLV. This TLV is transmitted if Voice VLAN parameters have been configured using the commands: ■ switchport voice dscp ■ switchport voice vlan ■ switchport voice vlan priority
`location`	Location Identification TLV. This TLV is transmitted if location information has been configured using the commands: ■ location elin-location-id ■ location civic-location identifier ■ location civic-location configuration ■ location coord-location identifier ■ location coord-location configuration ■ location elin-location
`inventory-management`	Inventory Management TLV Set, including the following TLVs: ■ Hardware Revision ■ Firmware Revision ■ Software Revision ■ Serial Number ■ Manufacturer Name ■ Model Name ■ Asset ID
`all`	All LLDP-MED Organizationally Specific TLVs.

Default By default LLDP-MED Capabilities, Network Policy, Location Identification and Extended Power-via-MDI TLVs are enabled. Therefore, if LLDP is enabled using the lldp run command, by default LLDP-MED advertisements are transmitted on ports that detect LLDP-MED neighbors connected to them.

Mode Interface Configuration

Usage LLDP-MED TLVs are only sent in advertisements via a port if there is an LLDP-MED-capable device connected to it. To see whether there are LLDP-MED capable devices connected to the ports, use the show lldp neighbors command.

Examples To enable inclusion of the Inventory TLV Set in advertisements transmitted via ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# lldp med-tlv-select inventory-management
```

To exclude the Inventory TLV Set in advertisements transmitted via ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# no lldp med-tlv-select inventory-management
```

To disable LLDP-MED advertisements transmitted via ports 1.0.1 and 1.0.7, disable all these TLVs using the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# no lldp med-tlv-select all
```

Related Commands

lldp non-strict-med-tlv-order-check

Use this command to enable non-strict order checking for LLDP-MED advertisements it receives. That is, use this command to enable LLDP to receive and store TLVs from LLDP-MED advertisements even if they do not use standard TLV order.

Use the no variant of this command to disable non-strict order checking for LLDP-MED advertisements, that is, to set strict TLV order checking, so that LLDP discards any LLDP-MED TLVs that occur before the LLDP-MED Capabilities TLV in an advertisement.

Syntax

```
lldp non-strict-med-tlv-order-check
no lldp non-strict-med-tlv-order-check
```

Default By default TLV non-strict order checking for LLDP-MED advertisements is disabled. That is, strict order checking is applied to LLDP-MED advertisements, according to ANSI/TIA-1057, and LLDP-MED TLVs in non-standard order are discarded.

Mode Global Configuration

Usage The ANSI/TIA-1057 specifies standard order for TLVs in LLDP-MED advertisements, and specifies that if LLDP receives LLDP advertisements with non-standard LLDP-MED TLV order, the TLVs in non-standard order should be discarded. This implementation of LLDP-MED follows the standard: it transmits TLVs in the standard order, and by default discards LLDP-MED TLVs that occur before the LLDP-MED Capabilities TLV in an advertisement. However, some implementations of LLDP transmit LLDP-MED advertisements with non-standard TLV order. To receive and store the data from these non-standard advertisements, enable non-strict order checking for LLDP-MED advertisements using this command.

Examples To enable strict TLV order checking, use the commands:

```
awplus# configure terminal
awplus(config)# lldp tlv-order-check
```

To disable strict TLV order checking, use the commands:

```
awplus# configure terminal
awplus(config)# no lldp tlv-order-check
```

Related Commands show running-config lldp

lldp notification-interval

This command sets the notification interval. This is the minimum interval between LLDP SNMP notifications (traps) of each kind (LLDP Remote Tables Change Notification and LLDP-MED Topology Change Notification).

The no variant of this command sets the notification interval back to its default.

Syntax

```
lldp notification-interval <5-3600>
no lldp notification-interval
```

Parameter	Description
<5-3600>	The interval in seconds.

Default The default notification interval is 5 seconds.

Mode Global Configuration

Examples To set the notification interval to 20 seconds, use the commands:

```
awplus# configure terminal
awplus(config)# lldp notification-interval 20
```

To set the notification interval back to its default, use the commands:

```
awplus# configure terminal
awplus(config)# no lldp notification-interval
```

Related Commands lldp notifications
show lldp

lldp notifications

This command enables the sending of LLDP SNMP notifications (traps) relating to specified ports.

The no variant of this command disables the sending of LLDP SNMP notifications for specified ports.

Syntax

```
lldp notifications
no lldp notifications
```

Default The sending of LLDP SNMP notifications is disabled by default.

Mode Interface Configuration

Examples To enable sending of LLDP SNMP notifications for ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# lldp notifications
```

To disable sending of LLDP SNMP notifications for ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# no lldp notifications
```

Related Commands

lldp notification-interval

snmp-server enable trap

lldp port-number-type

This command sets the type of port identifier used to enumerate, that is to count, the LLDP MIB local port entries. The LLDP MIB (*IEEE Standard 802.1AB-2005, Section 12, LLDP MIB Definitions*.) requires the port number value to count LLDP local port entries.

This command also enables you to optionally set an interface index to enumerate the LLDP MIB local port entries, if required by your management system.

The no variant of this command resets the type of port identifier back to the default setting (number).

Syntax

```
lldp port-number-type [number|ifindex]
no lldp port-number-type
```

Parameter	Description
`number`	Set the type of port identifier to a port number to enumerate the LLDP MIB local port entries.
`ifindex`	Set the type of port identifier to an interface index to enumerate the LLDP MIB local port entries.

Default The default port identifier type is number. The no variant of this command sets the port identifier type to the default.

Mode Global Configuration

Examples To set the type of port identifier used to enumerate LLDP MIB local port entries to port numbers, use the commands:

```
awplus# configure terminal
awplus(config)# lldp port-number-type number
```

To set the type of port identifier used to enumerate LLDP MIB local port entries to interface indexes, use the commands:

```
awplus# configure terminal
awplus(config)# lldp port-number-type ifindex
```

To reset the type of port identifier used to enumerate LLDP MIB local port entries the default (port numbers), use the commands:

```
awplus# configure terminal
awplus(config)# no lldp port-number-type
```

Related Commands show lldp

lldp reinit

This command sets the value of the reinitialization delay. This is the minimum time after disabling LLDP on a port before it can reinitialize.

The no variant of this command sets the reinitialization delay back to its default setting.

Syntax

```
lldp reinit <1-10>
no lldp reinit
```

Parameter	Description
<1-10>	The delay in seconds.

Default The default reinitialization delay is 2 seconds.

Mode Global Configuration

Examples To set the reinitialization delay to 3 seconds, use the commands:

```
awplus# configure terminal
awplus(config)# lldp reinit 3
```

To set the reinitialization delay back to its default, use the commands:

```
awplus# configure terminal
awplus(config)# no lldp reinit
```

Related Commands show lldp

lldp run

This command enables the operation of LLDP on the device.

The no variant of this command disables the operation of LLDP on the device. The LLDP configuration remains unchanged.

Syntax

```
lldp run
no lldp run
```

Default LLDP is disabled by default.

Mode Global Configuration

Examples To enable LLDP operation, use the commands:

```
awplus# configure terminal
awplus(config)# lldp run
```

To disable LLDP operation, use the commands:

```
awplus# configure terminal
awplus(config)# no lldp run
```

Related Commands show lldp

lldp timer

This command sets the value of the transmit interval. This is the interval between regular transmissions of LLDP advertisements.

The no variant of this command sets the transmit interval back to its default.

Syntax

```
lldp timer <5-32768>
no lldp timer
```

Parameter	Description
<5-32768>	The transmit interval in seconds. The transmit interval must be at least four times the transmission delay timer (lldp tx-delay command).

Default The default transmit interval is 30 seconds.

Mode Global Configuration

Examples To set the transmit interval to 90 seconds, use the commands:

```
awplus# configure terminal
awplus(config)# lldp timer 90
```

To set the transmit interval back to its default, use the commands:

```
awplus# configure terminal
awplus(config)# no lldp timer
```

Related Commands

lldp tx-delay
show lldp

lldp tlv-select

This command enables one or more optional TLVs, or all TLVs, for transmission in LLDP advertisements via the specified ports. The TLVs can be specified in any order; they are placed in LLDP frames in a fixed order (as described in IEEE 802.1AB). The mandatory TLVs (Chassis ID, Port ID, Time To Live, End of LLDPDU) are always included in LLDP advertisements.

In LLDP-MED advertisements the MAC/PHY Configuration/Status TLV will be always be included regardless of whether it is selected by this command.

The no variant of this command disables the specified optional TLVs, or all optional TLVs, for transmission in LLDP advertisements via the specified ports.

Syntax

```
lldp tlv-select {[<tlv>]...}

lldp tlv-select all

no lldp tlv-select {[<tlv>]...}

no lldp tlv-select all
```

Parameter	Description
<tlv>	The TLV to transmit in LLDP advertisements. One of these keywords: ■ port-description (specified by the description (interface) command on page 11.2) ■ system-name (specified by the hostname command on page 8.18) ■ system-description ■ system-capabilities ■ management-address ■ port-vlan ■ port-and-protocol-vlans ■ vlan-names ■ protocol-ids ■ mac-phy-config ■ power-management (Power Via MDI TLV) ■ link-aggregation ■ max-frame-size
`all`	All TLVs.

Default By default no optional TLVs are included in LLDP advertisements. The MAC/PHY Configuration/Status TLV (mac-phy-config) is included in LLDP-MED advertisements whether or not it is selected by this command.

Mode Interface Configuration

Examples To include the management-address and system-name TLVs in advertisements transmitted via ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# lldp tlv-select management-address system-
name
```

To include all optional TLVs in advertisements transmitted via ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# lldp tlv-select all
```

To exclude the management-address and system-name TLVs from advertisements transmitted via ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# no lldp tlv-select management-address
system-name
```

To exclude all optional TLVs from advertisements transmitted via ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# no lldp tlv-select all
```

Related Commands

lldp transmit receive

This command enables transmission and/or reception of LLDP advertisements to or from neighbors through the specified ports.

The no variant of this command disables transmission and/or reception of LLDP advertisements through specified ports.

Syntax

```
lldp {[transmit] [receive]}
no lldp {[transmit] [receive]}
```

Parameter	Description
`transmit`	Enable or disable transmission of LLDP advertisements via this port or ports.
`receive`	Enable or disable reception of LLDP advertisements via this port or ports.

Default LLDP advertisement transmission and reception are enabled on all ports by default.

Mode Interface Configuration

Examples To enable transmission of LLDP advertisements on ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# lldp transmit
```

To enable LLDP advertisement transmission and reception on ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# lldp transmit receive
```

To disable LLDP advertisement transmission and reception on ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# no lldp transmit receive
```

Related Commands show lldp interface

lldp tx-delay

This command sets the value of the transmission delay timer. This is the minimum time interval between transmitting LLDP advertisements due to a change in LLDP local information.

The no variant of this command sets the transmission delay timer back to its default setting.

Syntax

```
lldp tx-delay <1-8192>
no lldp tx-delay
```

Parameter	Description
<1-8192>	The transmission delay in seconds. The transmission delay cannot be greater than a quarter of the transmit interval (lldp timer command).

Default The default transmission delay timer is 2 seconds.

Mode Global Configuration

Examples To set the transmission delay timer to 12 seconds, use the commands:

```
awplus# configure terminal
awplus(config)# lldp tx-delay 12
```

To set the transmission delay timer back to its default, use the commands:

```
awplus# configure terminal
awplus(config)# no lldp tx-delay
```

Related Commands

no branch-road-name
sub-branch-road-name <sub-branch-road-name>
no sub-branch-road-name
street-name-pre-modifier <street-name-pre-modifier>
no street-name-pre-modifier
streetname-post-modifier <streetname-post-modifier>
no streetname-post-modifier
```

Parameter	Description
<country>	Upper-case two-letter country code, as specified in *ISO 3166*.
<state>	State (Civic Address (CA) Type 1): national subdivisions (state, canton, region).
<county>	County (CA Type 2): County, parish, gun (JP), district (IN).

Parameter(cont.)	Description(cont.)
<city>	City (CA Type 3): city, township, shi (JP).
<division>	City division (CA Type 4): City division, borough, city district, ward, chou (JP).
<neighborhood>	Neighborhood (CA Type 5): neighborhood, block.
<street-group>	Street group (CA Type 6): group of streets below the neighborhood level.
<leading-street-direction>	Leading street direction (CA Type 16).
<trailing-street-suffix>	Trailing street suffix (CA Type 17).
<street-suffix>	Street suffix (CA Type 18): street suffix or type.
<house-number>	House number (CA Type 19).
<house-number-suffix>	House number suffix (CA Type 20).
<landmark>	Landmark or vanity address (CA Type 21).
<additional-information>	Additional location information (CA Type 22).
<name>	Name (CA Type 23): residence and office occupant.
<postal-code>	Postal/zip code (CA Type 24).
<building>	Building (CA Type 25): structure.
<unit>	Unit (CA Type 26): apartment, suite.
<floor>	Floor (CA Type 27).
<room>	Room (CA Type 28).
<place-type>	Type of place (CA Type 29).
<postal-community-name>	Postal community name (CA Type 30).
<post-office-box>	Post office box (P.O. Box) (CA Type 31).
<additional-code>	Additional code (CA Type 32).
<seat>	Seat (CA Type 33): seat (desk, cubicle, workstation).
<primary-road-name>	Primary road name (CA Type 34).
<road-section>	Road section (CA Type 35).
<branch-road-name>	Branch road name (CA Type 36).
<sub-branch-road-name>	Sub-branch road name (CA Type 37).
<street-name-pre-modifier>	Street name pre-modifier (CA Type 38).
<street-name-post-modifier>	Street name post-modifier (CA Type 39).

Default By default no civic address location information is configured.

Mode Civic Address Location Configuration

Usage The country parameter must be configured before any other parameters can be configured; this creates the location. The country parameter cannot be deleted. One or more of the other parameters must be configured before the location can be assigned to a port. The country parameter must be entered as an upper-case two-letter country code, as specified in *ISO 3166*. All other parameters are entered as alpha-numeric strings. Do not configure all the civic address parameters (this would generate TLVs that are too long). Configure a subset of these parameters—enough to consistently and precisely identify the location of the device. If the location is to be used for Emergency Call Service (ECS), the particular ECS application may have guidelines for configuring the civic address location. For more information about civic address format, see "LLDP-MED: Location Identification TLV" on page 90.7.

To specify the civic address location, use the location civic-location identifier command. To delete the civic address location, use the no variant of the location civic-location identifier command. To assign the civic address location to particular ports, so that it can be advertised in TLVs from those ports, use the command location civic-location-id command.

Examples To configure civic address location 1 with location "27 Nazareth Avenue, Christchurch, New Zealand" in civic-address format, use the commands:

```
awplus# configure terminal
awplus(config)# location civic-location identifier 1
awplus(config-civic)# country NZ
awplus(config-civic)# city Christchurch
awplus(config-civic)# primary-road-name Nazareth
awplus(config-civic)# street-suffix Avenue
awplus(config-civic)# house-number 27
```

Related Commands
location civic-location-id
location civic-location identifier
show lldp local-info
show location

location civic-location identifier

Use this command to enter the Civic Address Location Configuration mode to configure the specified location.

Use the no variant of this command to delete a civic address location. This also removes the location from any ports it has been assigned to.

Syntax

```
location civic-location identifier <civic-loc-id>
no location civic-location identifier <civic-loc-id>
```

Parameter	Description
<civic-loc-id>	A unique civic address location ID, in the range 1 to 4095.

Default By default there are no civic address locations.

Mode Global Configuration

Usage To configure the location information for this civic address location identifier, use the location civic-location configuration command. To associate this civic location identifier with particular ports, use the location elin-location-id command.

Up to 400 locations can be configured on the switch for each type of location information, up to a total of 1200 locations.

Examples To enter Civic Address Location Configuration mode for the civic address location with ID 1, use the commands:

```
awplus# configure terminal
awplus(config)# location civic-location identifier 1
awplus(config-civic)#
```

To delete the civic address location with ID 1, use the commands:

```
awplus# configure terminal
awplus(config)# no location civic-location identifier 1
```

Related Commands
location civic-location-id
location civic-location configuration
show location
show running-config lldp

location civic-location-id

Use this command to assign a civic address location to the ports. The civic address location must already exist. This replaces any previous assignment of civic address location for the ports. Up to one location of each type can be assigned to a port.

Use the no variant of this command to remove a location identifier from the ports.

Syntax

```
location civic-location-id <civic-loc-id>
no location civic-location-id [<civic-loc-id>]
```

Parameter	Description
<civic-loc-id>	Civic address location ID, in the range 1 to 4095.

Default By default no civic address location is assigned to ports.

Mode Interface Configuration

Usage The civic address location associated with a port can be transmitted in Location Identification TLVs via the port.

Before using this command, create the location using the following commands:

- location civic-location identifier command
- location civic-location configuration command

If a civic-address location is deleted using the no variant of the location civic-location identifier command, it is automatically removed from all ports.

Examples To assign the civic address location 1 to port1.0.1, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# location civic-location-id 1
```

To remove a civic address location from port1.0.1, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# no location civic-location-id
```

Related Commands

lldp med-tlv-select
location civic-location identifier
location civic-location configuration
show location

location coord-location configuration

Use this command to configure a coordinate-based location. All parameters must be configured before assigning this location identifier to a port.

Syntax

```
latitude <latitude>
lat-resolution <lat-resolution>
longitude <longitude>
long-resolution <long-resolution>
altitude <altitude> {meters|floor}
alt-resolution <alt-resolution>
datum {wgs84|nad83-navd|nad83-mllw}
```

Parameter	Description
<lat-resolution>	Latitude resolution, as a number of valid bits, in the range 0 to 34.
<latitude>	Latitude value in degrees in the range -90.0 to 90.0
<long-resolution>	Longitude resolution, as a number of valid bits, in the range 0 to 34.
<longitude>	Longitude value in degrees, in the range -180.0 to 180.0.
<alt-resolution>	Altitude resolution, as a number of valid bits, in the range 0 to 30. A resolution of 0 can be used to indicate an unknown value.
<altitude>	Altitude value, in meters or floors.
`meters`	The altitude value is in meters.
`floors`	The altitude value is in floors.
`datum`	The geodetic system (or datum) that the specified coordinate values are based on.
`wgs84`	World Geodetic System 1984.
`nad83-navd`	North American Datum 1983 - North American Vertical Datum.
`nad83-mllw`	North American Datum 1983 - Mean Lower Low Water vertical datum.

Default By default no coordinate location information is configured.

Mode Coordinate Configuration

Usage Latitude and longitude values are always stored internally, and advertised in the Location Identification TLV, as 34-bit fixed-point binary numbers, with a 25-bit fractional part, irrespective of the number of digits entered by the user. Likewise altitude is stored as a 30-bit fixed point binary number, with an 8-bit fractional part. Because the user-entered decimal values are stored as fixed point binary numbers, they cannot always be represented exactly—the stored binary number is converted to a decimal number for display in the output of the show location command. For example, a user-entered latitude value of “2.77” degrees is displayed as “2.769999980926513671875000”.

The lat-resolution, long-resolution, and alt-resolution parameters allow the user to specify the resolution of each coordinate element as the number of valid bits in the internally-stored binary representation of the value. These resolution values can be used by emergency services to define a search area.

To specify the coordinate identifier, use the location coord-location identifier command. To remove coordinate information, delete the coordinate location by using the no variant of that command. To associate the coordinate location with particular ports, so that it can be advertised in TLVs from those ports, use the location elin-location-id command.

Example To configure the location for the White House in Washington DC, which has the coordinates based on the WGS84 datum of 38.89868 degrees North (with 22 bit resolution), 77.03723 degrees West (with 22 bit resolution), and 15 meters height (with 9 bit resolution), use the commands:

```
awplus# configure terminal
awplus(config)# location coord-location identifier 1
awplus(config-coord)# la-resolution 22
awplus(config-coord)# latitude 38.89868
awplus(config-coord)# lo-resolution 22
awplus(config-coord)# longitude -77.03723
awplus(config-coord)# alt-resolution 9
awplus(config-coord)# altitude 15 meters
awplus(config-coord)# datum wgs84
```

Related Commands
location coord-location-id
location coord-location identifier
show lldp local-info
show location

location coord-location identifier

Use this command to enter Coordinate Location Configuration mode for this coordinate location.

Use the no variant of this command to delete a coordinate location. This also removes the location from any ports it has been assigned to.

Syntax

```
location coord-location identifier <coord-loc-id>
no location coord-location identifier <coord-loc-id>
```

Parameter	Description
<coord-loc-id>	A unique coordinate location identifier, in the range 1 to 4095.

Default By default there are no coordinate locations.

Mode Global Configuration

Usage Up to 400 locations can be configured on the switch for each type of location information, up to a total of 1200 locations.

To configure this coordinate location, use the location coord-location configuration command. To associate this coordinate location with particular ports, so that it can be advertised in TLVs from those ports, use the location coord-location-id command.

Examples To enter Coordinate Location Configuration mode to configure the coordinate location with ID 1, use the commands:

```
awplus# configure terminal
awplus(config)# location coord-location identifier 1
awplus(config-coord)#
```

To delete coordinate location 1, use the commands:

```
awplus# configure terminal
awplus(config)# no location coord-location identifier 1
```

Related Commands

location coord-location-id
location coord-location configuration
show lldp local-info
show location

location coord-location-id

Use this command to assign a coordinate location to the ports. The coordinate location must already exist. This replaces any previous assignment of coordinate location for the ports. Up to one location of each type can be assigned to a port.

Use the no variant of this command to remove a location from the ports.

Syntax

```
location coord-location-id <coord-loc-id>
no location coord-location-id [<coord-loc-id>]
```

Parameter	Description
<coord-loc-id>	Coordinate location ID, in the range 1 to 4095.

Default By default no coordinate location is assigned to ports.

Mode Interface Configuration

Usage The coordinate location associated with a port can be transmitted in Location Identification TLVs via the port.

Before using this command, configure the location using the following commands:

- location coord-location identifier command
- location coord-location configuration command

If a coordinate location is deleted using the no variant of the location coord-location identifier command, it is automatically removed from all ports.

Examples To assign coordinate location 1 to port1.0.1, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# location coord-location-id 1
```

To remove a coordinate location from port1.0.1, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# no location coord-location-id
```

Related Commands

lldp med-tlv-select

location elin-location

Use this command to create or modify an ELIN location.

Use the no variant of this command to delete an ELIN location, and remove it from any ports it has been assigned to.

Syntax

```
location elin-location <elin> identifier <elin-loc-id>
no location elin-location identifier <elin-loc-id>
```

Parameter	Description
<elin>	Emergency Location Identification Number (ELIN) for Emergency Call Service (ECS), in the range 10 to 25 digits long. In North America, ELINs are typically 10 digits long.
<elin-loc-id>	A unique ELIN location identifier, in the range 1 to 4095.

Default By default there are no ELIN location identifiers.

Mode Global Configuration

Usage Up to 400 locations can be configured on the switch for each type of location information, up to a total of 1200 locations.

To assign this ELIN location to particular ports, so that it can be advertised in TLVs from those ports, use the location elin-location-id command.

Examples To create a new ELIN location with ID 1, and configure it with ELIN "1234567890", use the commands:

```
awplus# configure terminal
awplus(config)# location elin-location 1234567890 identifier 1
```

To delete existing ELIN location with ID 1, use the commands:

```
awplus# configure terminal
awplus(config)# no location elin-location identifier 1
```

Related Commands

location elin-location-id
show lldp local-info
show location

location elin-location-id

Use this command to assign an ELIN location to the ports. The ELIN location must already exist. This replaces any previous assignment of ELIN location for the ports. Up to one location of each type can be assigned to a port.

Use the no variant of this command to remove a location identifier from the ports.

Syntax

```
location elin-location-id <elin-loc-id>
no location elin-location-id [<elin-loc-id>]
```

Parameter	Description
<elin-loc-id>	ELIN location identifier, in the range 1 to 4095.

Default By default no ELIN location is assigned to ports.

Mode Interface Configuration

Usage An ELIN location associated with a port can be transmitted in Location Identification TLVs via the port.

Before using this command, configure the location using the location elin-location command.

If an ELIN location is deleted using the no variant of one of the location elin-location command, it is automatically removed from all ports.

Examples To assign ELIN location 1 to port 1.0.1, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# location elin-location-id 1
```

To remove an ELIN location from port 1.0.1, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# no location elin-location-id
```

Related Commands

show debugging lldp

This command displays LLDP debug settings for specified ports. If no port list is supplied, LLDP debug settings for all ports are displayed.

Syntax `show debugging lldp [interface <port-list>]`

Parameter	Description
`<port-list>`	The ports for which the LLDP debug settings are shown.

Mode User Exec and Privileged Exec

Examples To display LLDP debug settings for all ports, use the command:

```
awplus# show debugging lldp
```

To display LLDP debug settings for ports 1.0.1 to 1.0.9, use the command:

```
awplus# show debugging lldp interface port1.0.1-1.0.9
```

Output Figure 91-1: Example output from the **show debugging lldp** command

```
LLDP Debug settings:
Debugging for LLDP internal operation is on
Port        Rx     RxPkt    Tx     TxPkt
-------------------------------------
1.0.1       Yes    Yes      No     No
1.0.2       Yes    No       No     No
1.0.3       No     No       No     No
1.0.4       Yes    Yes      Yes    No
1.0.5       Yes    No       Yes    No
1.0.6       No     No       Yes    No
1.0.7       Yes    Yes      Yes    Yes
1.0.8       Yes    No       Yes    Yes
1.0.9       No     No       Yes    Yes
```

Table 91-1: Parameters in the output of the **show debugging lldp** command

Parameter	Description
`Port`	Port name.
`Rx`	Whether debugging of LLDP receive is enabled on the port.
`RxPkt`	Whether debugging of LLDP receive packet dump is enabled on the port.
`Rx`	Whether debugging of LLDP transmit is enabled on the port.
`RxPkt`	Whether debugging of LLDP transmit packet dump is enabled on the port.

Related Commands debug lldp

show lldp

This command displays LLDP status and global configuration settings.

Syntax `show lldp`

Mode User Exec and Privileged Exec

Example To display LLDP status and global configuration settings, use the command:

```
awplus# show lldp
```

Output

Figure 91-2: Example output from the **show lldp** command

```
awplus# show lldp

LLDP Global Configuration:              [Default Values]
LLDP Status ............... Enabled     [Disabled]
Notification Interval ..... 5 secs      [5]
Tx Timer Interval ......... 30 secs     [30]
Hold-time Multiplier ...... 4           [4]
(Computed TTL value ....... 120 secs)
Reinitialization Delay .... 2 secs      [2]
Tx Delay .................. 2 secs      [2]
Port Number Type........... Ifindex     [Port-Number]
Fast Start Count .......... 5           [3]

LLDP Global Status:
Total Neighbor Count ...... 47
Neighbors table last updated 0 hrs 0 mins 43 secs ago
```

Table 91-2: Parameters in the output of the **show lldp** command

Parameter	Description
`LLDP Status`	Whether LLDP is enabled. Default is disabled.
`Notification Interval`	Minimum interval between LLDP notifications.
`Tx Timer Interval`	Transmit interval between regular transmissions of LLDP advertisements.
`Hold-time Multiplier`	The holdtime multiplier. The transmit interval is multiplied by the holdtime multiplier to give the Time To Live (TTL) value that is advertised to neighbors.
`Reinitialization Delay`	The reinitialization delay. This is the minimum time after disabling LLDP transmit on a port before it can reinitialize again.
`Tx Delay`	The transmission delay. This is the minimum time interval between transmitting advertisements due to a change in LLDP local information.
`Port Number Type`	The type of port identifier used to enumerate LLDP MIB local port entries, as set by the lldp port-number-type command.
`Fast Start Count`	The number of times fast start advertisements are sent for LLDP-MED.

Table 91-2: Parameters in the output of the **show lldp** command(cont.)

Parameter	Description
`Total Neighbor Count`	Number of LLDP neighbors discovered on all ports.
`Neighbors table last updated`	The time since the LLDP neighbor table was last updated.

Related Commands

show lldp interface
show running-config lldp

show lldp interface

This command displays LLDP configuration settings for specified ports. If no port list is specified, LLDP configuration for all ports is displayed.

Syntax `show lldp interface [<port-list>]`

Parameter	Description
<port-list>	The ports for which the LLDP configuration settings are to be shown.

Mode User Exec and Privileged Exec

Examples To display LLDP configuration settings for ports 1.0.1 to 1.0.8, use the command:

```
awplus# show lldp interface port1.0.1-1.0.8
```

To display LLDP configuration settings for all ports, use the command:

```
awplus# show lldp interface
```

Output

Figure 91-3: Example output from the **show lldp interface** command

```
awplus# show lldp interface port1.0.1-1.0.8

Table 91-3: Parameters in the output of the **show lldp interface** command

Parameter	Description
`Port`	Port name.
`Rx`	Whether reception of LLDP advertisements is enabled on the port.
`Tx`	Whether transmission of LLDP advertisements is enabled on the port.
`Notif`	Whether sending SNMP notification for LLDP is enabled on the port: ■ RM = Remote Tables Change Notification ■ TP = LLDP-MED Topology Change Notification
`Management Addr`	Management address advertised to neighbors.
`Base TLVs Enabled for Tx`	List of optional Base TLVs enabled for transmission: ■ Pd = Port Description ■ Sn =System Name ■ Sd = System Description ■ Sc =System Capabilities ■ Ma = Management Address
`802.1 TLVs Enabled for Tx`	List of optional 802.1 TLVs enabled for transmission: ■ Pv = Port VLAN ID ■ Pp = Port And Protocol VLAN ID ■ Vn = VLAN Name ■ Pi =Protocol Identity
`802.3 TLVs Enabled for Tx`	List of optional 802.3 TLVs enabled for transmission: ■ Mp = MAC/PHY Configuration/Status ■ Po = Power Via MDI (PoE) ■ La = Link Aggregation ■ Mf = Maximum Frame Size
`MED TLVs Enabled for Tx`	List of optional LLDP-MED TLVs enabled for transmission: ■ Mc = LLDP-MED Capabilities ■ Np = Network Policy ■ Lo = Location Information, ■ Pe = Extended Power-Via-MDI ■ In = Inventory

Related Commands

show lldp
show running-config lldp

show lldp local-info

This command displays local LLDP information that can be transmitted through specified ports. If no port list is entered, local LLDP information for all ports is displayed.

Syntax

```
show lldp local-info [base] [dot1] [dot3] [med] [interface
   <port-list>]
```

Parameter	Description
`base`	Information for base TLVs.
`dot1`	Information for 802.1 TLVs.
`dot3`	Information for 802.3 TLVs.
`med`	Information for LLDP-MED TLVs.
<port-list>	The ports for which the local information is to be shown.

Mode User Exec and Privileged Exec

Usage Whether and which local information is transmitted in advertisements via a port depends on:

- whether the port is set to transmit LLDP advertisements (lldp transmit receive command)
- which TLVs it is configured to send (lldp tlv-select command, lldp med-tlv-select command)

Examples To display local information transmitted via port 1.0.1, use the command:

```
awplus# show lldp local-info interface port1.0.1
```

To display local information transmitted via all ports, use the command:

```
awplus# show lldp local-info
```

Output

Table 91-4: Parameters in the output of the **show lldp local-info** command

Parameter	Description
Chassis ID Type	Type of the Chassis ID.
Chassis ID	Chassis ID that uniquely identifies the local device.
Port ID Type	Type of the Port ID.
Port ID	Port ID of the local port through which advertisements are sent.
TTL	Number of seconds that the information advertised by the local port remains valid.
Port Description	Port description of the local port, as specified by the description (interface) command on page 11.2.
System Name	System name, as specified by the hostname command on page 8.18.
System Description	System description.
System Capabilities (Supported)	Capabilities that the local port supports.
System Capabilities (Enabled)	Enabled capabilities on the local port.
Management Addresses	Management address associated with the local port. To change this, use the lldp management-address command.
Port VLAN ID (PVID)	VLAN identifier associated with untagged or priority tagged frames received via the local port.
Port & Protocol VLAN (Supported)	Whether Port & Protocol VLANs (PPV) is supported on the local port.
Port & Protocol VLAN (Enabled)	Whether the port is in one or more Port & Protocol VLANs.
Port & Protocol VLAN (VIDs)	List of identifiers for Port & Protocol VLANs that the port is in.
VLAN Names	List of VLAN names for VLANs that the local port is assigned to.
Protocol IDs	List of protocols that are accessible through the local port.
MAC/PHY Auto-negotiation	Auto-negotiation support and current status of the 802.3 LAN on the local port.
Power Via MDI (PoE)	PoE-capability and current status on the local port.
Port Class	Whether the device is a PSE (Power Sourcing Entity) or a PD (Powered Device)
Pair Control Ability	Whether power pair selection can be controlled
Power Pairs	Which power pairs are selected for power ("Signal Pairs" or "Spare Pairs") if pair selection can be controlled

Table 91-4: Parameters in the output of the **show lldp local-info** command(cont.)

Parameter	Description
Power Class	The power class of the PD device on the port (class 0, 1, 2, 3 or 4)
Link Aggregation	Whether the link is capable of being aggregated and it is currently in an aggregation.
Aggregated Port-ID	Aggregated port identifier.
Maximum Frame Size	The maximum frame size capability of the implemented MAC and PHY.
LLDP-MED Device Type	LLDP-MED device type
LLDP-MED Capabilities	Capabilities LLDP-MED capabilities supported on the local port.
Network Policy	List of network policies configured on the local port.
VLAN ID	VLAN identifier for the port for the specified application type
Tagged Flag	Whether the VLAN ID is to be used as tagged or untagged
Layer-2 Priority:	Layer 2 User Priority (in the range 0 to 7)
DSCP Value	Diffserv codepoint (in the range 0 to 63)
Location Identification	Location configured on the local port.
Extended Power Via MDI (PoE)	PoE-capability and current status of the PoE parameters for Extended Power-Via-MDI TLV on the local port.
Power Source	The power source the switch currently uses; either primary power or backup power.
Power Priority	The power priority configured on the port; either critical, high or low.
Power Value	The total power the switch can source over a maximum length cable to a PD device on the port. The value shows the power value in Watts from the PD side.
Inventory Management	Inventory information for the device.

Related Commands

description (interface)

Table 91-5: Parameters in the output of the **show lldp neighbors** command

Parameter	Description
`Local Port`	Local port on which the neighbor information was received.
`Neighbor Chassis ID`	Chassis ID that uniquely identifies the neighbor.
`Neighbor Port Name`	Port ID of the neighbor.
`Neighbor Sys Name`	System name of the LLDP neighbor.

Table 91-5: Parameters in the output of the **show lldp neighbors** command(cont.)

Parameter	Description
`Neighbor Capability`	Capabilities that are supported and enabled on the neighbor.
`System Capability`	System Capabilities of the LLDP neighbor.
`MED Device Type`	LLDP-MED Device class (Class I, II, III or Network Connectivity)
`MED Power Source`	LLDP-MED Power Source

Related Commands show lldp neighbors detail

show lldp neighbors detail

This command displays in detail the information received from neighbors via specified ports. If no port list is supplied, detailed neighbor information for all ports is displayed.

Syntax `show lldp neighbors detail [base] [dot1] [dot3] [med] [interface <port-list>]`

Parameter	Description
`base`	Information for base TLVs.
`dot1`	Information for 802.1 TLVs.
`dot3`	Information for 803.1 TLVs.
`med`	Information for LLDP-MED TLVs.
<port-list>	The ports for which the neighbor information is to be shown.

Mode User Exec and Privileged Exec

Examples To display detailed neighbor information received via all ports, use the command:

```
awplus# show lldp neighbors detail
```

To display detailed neighbor information received via ports 1.0.1, use the command:

```
awplus# show lldp neighbors detail interface port1.0.1
```

Output

Figure 91-6: Example output from the **show lldp neighbors detail** command

```
awplus# show lldp neighbors detail interface port1.0.1
LLDP Detailed Neighbor Information:

Local port1.0.1:

Table 91-6: Parameters in the output of the **show lldp neighbors detail** command

Parameter	Description
`Chassis ID Type`	Type of the Chassis ID.
`Chassis ID`	Chassis ID that uniquely identifies the neighbor.
`Port ID Type`	Type of the Port ID.
`Port ID`	Port ID of the neighbor.
`TTL`	Number of seconds that the information advertised by the neighbor remains valid.
`Port Description`	Port description of the neighbor's port.
`System Name`	Neighbor's system name.

Table 91-6: Parameters in the output of the **show lldp neighbors detail** command(cont.)

Parameter	Description
System Description	Neighbor's system description.
System Capabilities (Supported)	Capabilities that the neighbor supports.
System Capabilities (Enabled)	Capabilities that are enabled on the neighbor.
Management Addresses	List of neighbor's management addresses.
Port VLAN ID (PVID)	VLAN identifier associated with untagged or priority tagged frames for the neighbor port.
Port & Protocol VLAN (Supported)	Whether Port & Protocol VLAN is supported on the LLDP neighbor.
Port & Protocol VLAN (Enabled)	Whether Port & Protocol VLAN is enabled on the LLDP neighbor.
Port & Protocol VLAN (VIDs)	List of Port & Protocol VLAN identifiers.
VLAN Names	List of names of VLANs that the neighbor's port belongs to.
Protocol IDs	List of protocols that are accessible through the neighbor's port.
MAC/PHY Auto-negotiation	Auto-negotiation configuration and status
Power Via MDI (PoE)	PoE configuration and status of 802.3 Power-Via-MDI TLV
Link Aggregation	Link aggregation information
Maximum Frame Size	The maximum frame size capability
LLDP-MED Device Type	LLDP-MED Device type
LLDP-MED Capabilities	LLDP-MED capabilities supported
Network Policy	List of network policies
Location Identification	Location information
Extended Power Via MDI (PoE)	PoE-capability and current status
Inventory Management	Inventory information

Related Commands show lldp neighbors

show lldp statistics

This command displays the global LLDP statistics (packet and event counters).

Syntax `show lldp statistics`

Mode User Exec and Privileged Exec

Example To display global LLDP statistics information, use the command:

```
awplus# show lldp statistics
```

Output

Figure 91-7: Example output from the **show lldp statistics** command

```
awplus# show lldp statistics

Global LLDP Packet and Event counters:

  Frames:     Out ................... 345
              In .................... 423
              In Errored ............ 0
              In Dropped ............ 0
  TLVs:       Unrecognized .......... 0
              Discarded ............. 0
  Neighbors:  New Entries ........... 20
              Deleted Entries ....... 20
              Dropped Entries ....... 0
              Entry Age-outs ........ 20
```

Table 91-7: Parameters in the output of the **show lldp statistics** command

Parameter	Description
`Frames Out`	Number of LLDPDU frames transmitted.
`Frames In`	Number of LLDPDU frames received.
`Frames In Errored`	Number of invalid LLDPDU frames received.
`Frames In Dropped`	Number of LLDPDU frames received and discarded for any reason.
`TLVs Unrecognized`	Number of LLDP TLVs received that are not recognized but the TLV type is in the range of reserved TLV types.
`TLVs Discarded`	Number of LLDP TLVs discarded for any reason.
`Neighbors New Entries`	Number of times the information advertised by neighbors has been inserted into the neighbor table.
`Neighbors Deleted Entries`	Number of times the information advertised by neighbors has been removed from the neighbor table.
`Neighbors Dropped Entries`	Number of times the information advertised by neighbors could not be entered into the neighbor table because of insufficient resources.
`Neighbors Entry Age-outs Entries`	Number of times the information advertised by neighbors has been removed from the neighbor table because the information TTL interval has expired.

Related Commands clear lldp statistics
show lldp statistics interface

show lldp statistics interface

This command displays the LLDP statistics (packet and event counters) for specified ports. If no port list is supplied, LLDP statistics for all ports are displayed.

Syntax

```
show lldp statistics interface [<port-list>]
```

Parameter	Description
<port-list>	The ports for which the statistics are to be shown.

Mode User Exec and Privileged Exec

Examples To display LLDP statistics information for all ports, use the command:

```
awplus# show lldp statistics interface
```

To display LLDP statistics information for ports 1.0.1 and 1.0.7, use the command:

```
awplus# show lldp statistics interface port1.0.1,port1.0.7
```

Output

Figure 91-8: Example output from the **show lldp statistics interface** command

```
awplus# show lldp statistics interface port1.0.1,port1.0.7

Related Commands

clear lldp statistics
show lldp statistics

show location

Use this command to display selected location information configured on the switch.

Syntax

```
show location {civic-location|coord-location|elin-location}

show location {civic-location|coord-location|elin-location}
   identifier {<civic-loc-id>|<coord-loc-id>|<elin-loc-id>}

show location {civic-location|coord-location|elin-location} interface
   <port-list>
```

Parameter	Description
`civic-location`	Display civic location information.
`coord-location`	Display coordinate location information.
`elin-location`	Display ELIN location information.
<civic-loc-id>	Civic address location identifier, in the range 1 to 4095.
<coord-loc-id>	Coordinate location identifier, in the range 1 to 4095.
<elin-loc-id>	ELIN location identifier, in the range 1 to 4095.
<port-list>	Ports to display information about.

Mode User Exec and Privileged Exec

Examples To display a civic address location configured on port1.0.1, use the command:

```
awplus# show location civic-location interface port1.0.1
```

Figure 91-9: Example output from the **show location** command

```
awplus# show location civic-location interface port1.0.1
Port     ID   Element Type          Element Value
-------------------------------------------------------------
1.0.1    1    Country               NZ
              City                  Christchurch
              Street-suffix         Avenue
              House-number          27
              Primary-road-name     Nazareth
```

To display coordinate location information configured on the identifier 1, use the command:

```
awplus# show location coord-location identifier 1
```

Figure 91-10: Example output from the **show location** command

```
awplus# show location coord-location identifier 1
  ID  Element Type             Element Value
------------------------------------------------------------------
  1   Latitude Resolution      15 bits
      Latitude                 38.898648113012313842773437 5 degrees
      Longitude Resolution     15 bits
      Longitude                130.232323229312896728515625 0 degrees
      Altitude Resolution      10 bits
      Altitude                 2.50000000 meters
      Map Datum                WGS 84
```

The coordinate location information displayed may differ from the information entered because it is stored in binary format. For more information, see the location coord-location configuration command.

To display all ELIN location information configured on the switch, use the command:

```
awplus# show location elin-location
```

Figure 91-11: Example output from the show location command

```
awplus# show location elin-location
  ID  ELIN

Chapter 92: SMTP Commands

Command List 92.2
debug mail 92.2
delete mail 92.3
mail 92.4
mail from 92.5
mail smtpserver 92.6
show counter mail 92.7
show mail 92.8
undebug mail 92.8

Command List

This chapter provides an alphabetical reference for commands used to configure SMTP.

For information about modifying or redirecting the output from show commands to a file, see "Controlling "show" Command Output" on page 1.41.

debug mail

This command turns on debugging for sending emails.

The no variant of this command turns off debugging for sending emails.

Syntax

```
debug mail
no debug mail
```

Mode Privileged Exec

Examples To turn on debugging for sending emails, use the command:

```
awplus# debug mail
```

To turn off debugging for sending emails, use the command:

```
awplus# no debug mail
```

Related Commands

delete mail
mail
mail from
mail smtpserver
show mail
show counter mail
undebug mail

delete mail

This command deletes mail from the queue.

Syntax `delete mail [mail-id <mail-id>|all]`

Parameter	Description	
`mail-id`	Deletes a single mail from the mail queue.	
	<mail-id>	An unique mail ID number. Use the show mail command to display this for an item of mail.
`all`	Delete all the mail in the queue.	

Mode Privileged Exec

Examples To delete a unique mail item `20060912142356.1234` from the queue, use the command:

```
awplus# delete mail 20060912142356.1234
```

To delete all mail from the queue, use the command:

```
awplus# delete mail all
```

Related Commands
debug mail
mail
mail from
mail smtpserver
show mail

mail

This command sends an email using the SMTP protocol. If you specify a file the text inside the file is sent in the message body.

If you do not specify the to, file, or subject parameters, the CLI prompts you for the missing information.

Before you can send mail using this command, you must specify the sending email address using the mail from command and a mail server using the mail smtpserver command.

Syntax `mail [{to <to>|subject <subject>|file <filename>}]`

Parameter	Description	
`to`	The email recipient.	
	<to>	Email address.
`subject`	Description of the subject of this email. Use quote marks when the subject text contains spaces.	
	<subject>	String.
`file`	File to insert as text into the message body.	
	<filename>	String.

Mode Privileged Exec

Example To send an email to `rei@nerv.com` with the subject `dummy plug configuration`, and with the message body inserted from the file `plug.conf` use the command:

```
awplus# mail rei@nerv.com subject dummy plug configuration
        filename plug.conf
```

Related Commands
debug mail
delete mail
mail from
mail smtpserver
show mail
show counter mail

mail from

This command sets an email address for the 'mail from' SMTP command. You must specify a sending email address with this command before you can send any email.

Syntax `mail from <from>`

Parameter	Description
<from>	The email address that the mail is sent from.

Mode Global Configuration

Example To set the email address you are sending mail from to "kaji@nerv.com, use the command:

```
awplus(config)# mail from kaji@nerv.com
```

Related Commands
delete mail
mail
mail smtpserver
show mail

mail smtpserver

This command sets the IP address of the SMTP server that your device sends email to. You must specify a mail server with this command before you can send any email.

Syntax `mail smtpserver <ip-address>`

Parameter	Description
<ip-address>	Internet Protocol (IP) Address for the mail server specified.

Mode Global Configuration

Example To specify a mail server at 192.168.0.1, use the command:

```
awplus# mail smtpserver 192.168.0.1
```

Related Commands
debug mail
delete mail
mail
mail from
show mail
show counter mail

show counter mail

This command displays the mail counters.

Syntax `show counter mail`

Mode User Exec and Privileged Exec

Output Figure 92-1: Example output from the **show counter mail** command

```
Mail Client (SMTP) counters
Mails Sent            ......... 0
Mails Sent Fails      ......... 1
```

Table 92-1: Parameters in the output of the **show counter mail** command

Parameter	Description
`Mails Sent`	The number of emails sent successfully since the last device restart.
`Mails Sent Fails`	The number of emails the device failed to send since the last device restart.

Example To show the emails in the queue use the command:

```
awplus# show counter mail
```

Related Commands
debug mail
delete mail
mail
mail from
show mail

show mail

This command displays the emails in the queue.

Syntax `show mail`

Mode Privileged Exec

Example To display the emails in the queue use the command:

mail
show counter mail

undebug mail

This command applies the functionality of the no debug mail command on page 92.2.

Chapter 93: RMON Introduction and Configuration

Introduction 93.2
Overview 93.2
RMON Configuration Example 93.3

Introduction

The chapter describes the Remote Network MONitoring (RMON) service on the switch, and describes a configuration example showing how to set up an RMON alarm.

This RMON alarm configuration example described creates SNMP traps and log messages when the rate of receipt of Broadcast packets on a switch port exceeds a threshold, and creates SNMP traps and log messages when the rate of receipt of Broadcast packets on a switch drops below a lower threshold.

For detailed information about the commands used to configure RMON, see Chapter 94, RMON Commands

RMON is disabled by default in AlliedWare Plus™. No RMON alarms or events are configured.

Overview

The Remote Network MONitoring (RMON) MIB (RFC2819) was developed by the IETF to support monitoring and protocol analysis of LANs with a focus on Layer 1 and 2 information in networks. RMON is an industry standard that provides the functionality in network analyzers.

An RMON implementation operates in a client/server model. Monitoring devices (or 'probes') contain RMON agents that collect information and analyze packets. The probes are servers and the Network Management applications that communicate with them are clients. While agent configuration and data collection uses SNMP, RMON operates differently than SNMP systems:

- Probes have responsibility for data collection and processing, reducing SNMP traffic and reducing processing load for clients.
- Information is only transmitted to the management application when required, not polled.

RMON is mainly used for 'flow-based' monitoring, while SNMP is mainly used for 'device-based' management. RMON data collected deals mainly with traffic patterns on the network, and SNMP data collected usually deals with the status of individual devices on the network.

One disadvantage of flow based monitoring is that remote devices have much more of the management burden, and require more resources. AlliedWare Plus minimizes the management and resources burden by implementing a subset of the RMON MIB group to provide a minimal RMON agent implementation supporting statistics, history, alarms, and events.

The RMON groups supported in AlliedWare Plus™ are:

- Statistics - collects ethernet statistics on a switch port, such as utilization and collisions.
- History - collects a history of ethernet statistics on a switch port.
- Alarms - monitor a MIB object for a specified interval, trigger an alarm at a specified value (the 'rising threshold'), and resets the alarm at another value (the 'falling threshold'). Alarms are used with events to trigger alarms, which generate logs or SNMP traps.
- Events - specify the action to take when an event is triggered by an alarm. The action of an event can generate a log or an SNMP trap.

RMON Configuration Example

This configuration example sets up an RMON alarm to create SNMP traps and log messages. This RMON alarm creates SNMP traps and log messages when the rate of receipt of Broadcast packets on a switch port exceeds a threshold, and creates SNMP traps and log messages when the rate of receipt of Broadcast packets on a switch port drops below a lower threshold.

Step 1: Set up an RMON collection on the switch port that is being monitored.

Use the following commands to configure this functionality:

```
awplus# configure terminal
awplus(config)# interface port1.0.4
awplus(config-if)# rmon collection stats 4
```

This will cause the software to build a table in which it stores statistics relating to the switch port.

Step 2: Define an RMON event that will be called by the Alarm when the thresholds are passed.

Create this as a 'trap and log' event, so that both an SNMP trap and a log message will be generated. The trap will be sent to the SNMP community named 'public'.

Use the following command to configure this functionality:

```
awplus(config-if)# rmon event 10 log trap public
```

Step 3: Create the RMON alarm.

Every 5 seconds, the alarm checks the broadcast packet counter in RMON collection stats 4. If the change in the value of that counter over the 5 second interval exceeds 5000 (1000 broadcasts per second), the alarm will trigger the event defined in step 2 above.

Additionally, when the rate broadcast falls below 500 broadcasts per 5 seconds, then the alarm will trigger the event defined in step 2 above again.

Use the below command to configure this functionality:

```
awplus(config-if)# rmon alarm 5 etherStatsBroadcastPkts.4
                   interval 5 delta rising-threshold 5000
                   event 10 falling-threshold 500 event 10
```

For the variable '`etherStatsBroadcastPkts.4`' in this command, note that '`.4`' refers to the index number of the RMON collection stats 4 as defined on `port1.0.4`.

So, '`etherStatsBroadcastPkts.4`' refers to 'Received broadcasts' in RMON collection stats 4. Further counters for RMON are defined in section 5 of RFC 1757.

Step 4: Enable RMON traps.

To ensure that the SNMP trap is sent, you need to enabled RMON traps, and you need to define a trap host in SNMP. Use the below commands to configure this functionality:

```
awplus# configure terminal
awplus(config)# snmp-server
awplus(config)# snmp-server enable trap rmon
awplus(config)# snmp-server community public
awplus(config)# snmp-server host 192.168.2.254 version 2c
public
```

Note that the resulting log message will be of the form listed below:

```
RMON [1024]: Alarm Index 5 alarm Rising Threshold 5000 alarm
Value 5117 alarm Rising event Index 10 event description
RMON_SNMP
```

Chapter 94: RMON Commands

Command List 94.2
rmon alarm 94.2
rmon collection history 94.4
rmon collection stats 94.5
rmon event 94.6
show rmon alarm 94.7
show rmon event 94.8
show rmon history 94.10
show rmon statistics 94.12

Command List

This chapter provides an alphabetical reference for commands used to configure Remote Monitoring (RMON).

For an introduction to RMON and an RMON configuration example, see Chapter 93, RMON Introduction and Configuration

RMON is disabled by default in AlliedWare Plus™. No RMON alarms or events are configured.

For information about modifying or redirecting the output from show commands to a file, see "Controlling "show" Command Output" on page 1.41.

rmon alarm

Use this command to configure an RMON alarm to monitor the value of an SNMP object, and to trigger specified events when the monitored object crosses specified thresholds.

To specify the action taken when the alarm is triggered, use the event index of an event defined by the rmon event command.

Use the no variant of this command to remove the alarm configuration.

Note Only alarms for switch port interfaces, not for VLAN interfaces, can be configured.

Syntax

```
rmon alarm <alarm-index> <oid> interval <1-4294967295> {delta|
   absolute} rising-threshold <1-2147483647> event <rising-event-
   index> falling-threshold <1-2147483647> event <falling-event-
   index> [owner <owner>]

no rmon alarm <alarm-index>
```

Parameter	Description
<alarm-index>	*<1-65535>* Alarm entry index value.
<oid>	The variable SNMP MIB Object Identifier (OID) name to be monitored, in the format etherStatsEntry.field.<*stats-index*>. For example, etherStatsEntry.5.22 is the OID for the etherStatsPkts field in the etherStatsEntry table for the interface defined by the <*stats-index*> 22 in the rmon collection stats command.
`interval <1-4294967295>`	Polling interval in seconds.
`delta`	The RMON MIB alarmSampleType: the change in the monitored MIB object value between the beginning and end of the polling interval.
`absolute`	The RMON MIB alarmSampleType: the value of the monitored MIB object.

Parameter(cont.)	Description(cont.)
`rising-threshold <1-2147483647>`	Rising threshold value of the alarm entry in seconds.
`<rising-event-index>`	`<1-65535>` The event to be triggered when the monitored object value reaches the rising threshold value. This is an event index of an event specified by the rmon event command.
`falling-threshold <1-2147483647>`	Falling threshold value of the alarm entry in seconds.
`<falling-event-index>`	`<1-65535>` The event to be triggered when the monitored object value reaches the falling threshold value. This is an event index of an event specified by the rmon event command.
`owner <owner>`	Arbitrary owner name to identify the alarm entry.

Default By default, there are no alarms.

Mode Global Configuration

Usage Note that the SNMP MIB Object Identifier (OID) indicated in the command syntax with <*oid*> must be specified as a dotted decimal value with the form etherStatsEntry.field.<*stats-index*>.

Example To configure an alarm to monitor the change per minute in the etherStatsPkt value for interface 22 (defined by stats-index 22 in the rmon collection stats command), to trigger event 2 (defined by the rmon event command) when it reaches the rising threshold 400, and to trigger event 3 when it reaches the falling threshold 200, and identify this alarm as belonging to Maria, use the commands:

```
awplus# configure terminal

awplus(config)# rmon alarm 229 etherStatsEntry.22.5 interval 60
                delta rising-threshold 400 event 2 falling-
                threshold 200 event 3 owner maria
```

Related Commands rmon collection stats
rmon event

rmon collection history

Use this command to create a history statistics control group to store a specified number of snapshots (buckets) of the standard RMON statistics for the switch port, and to collect these statistics at specified intervals. If there is sufficient memory available, then the device will allocate memory for storing the set of buckets that comprise this history control.

Use the no variant of this command to remove the specified history control configuration.

Note Only a history for switch port interfaces, not for VLAN interfaces, can be collected.

Syntax

```
rmon collection history <history-index> [buckets <1-65535>]
   [interval <1-3600>] [owner <owner>]

no rmon collection history <history-index>
```

Parameter	Description
<history-index>	*<1-65535>* A unique RMON history control entry index value.
buckets *<1-65535>*	Number of requested buckets to store snapshots. Default 50 buckets.
interval *<1-3600>*	Polling interval in seconds. Default 1800 second polling interval.
owner *<owner>*	Owner name to identify the entry.

Default The default interval is 1800 seconds and the default buckets is 50 buckets.

Mode Interface Configuration

Example

```
awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# rmon collection history 200 buckets 500
                   interval 600 owner herbert

awplus# configure terminal
awplus(config)# interface port1.0.2
awplus(config-if)# no rmon collection history 200
```

rmon collection stats

Use this command to enable the collection of RMON statistics on a switch port, and assign an index number by which to access these collected statistics.

Use the no variant of this command to stop collecting RMON statistics on this switch port.

Note Only statistics for switch port interfaces, not for VLAN interfaces, can be collected.

Syntax

```
rmon collection stats <collection-index> [owner <owner>]
no rmon collection stats <collection-index>
```

Parameter	Description
<collection-index>	*<1-65535>* Give this collection of statistics an index number to uniquely identify it. This is the index to use to access the statistics collected for this switch port.
owner *<owner>*	An arbitrary owner name to identify this statistics collection entry.

Default RMON statistics are not enabled by default.

Mode Interface Configuration

Example

```
awplus# configure terminal
awplus(config)# interface port1.0.3
awplus(config-if)# rmon collection stats 200 owner myrtle

awplus# configure terminal
awplus(config)# interface port1.0.3
awplus(config-if)# no rmon collection stats 200
```

rmon event

Use this command to create an event definition for a log or a trap or both. The event index for this event can then be referred to by the rmon alarm command.

Use the no variant of this command to remove the event definition.

Note Only the events for switch port interfaces, not for VLAN interfaces, can be collected.

Syntax

```
rmon event <event-index> [description <description>|owner <owner>|
   trap <trap>]

rmon event <event-index> [log [description <description>|
   owner <owner>|trap <trap>] ]

rmon event <event-index> [log trap [description <description>|
   owner <owner>] ]

no rmon event <event-index>
```

Parameter	Description
<event-index>	*<1-65535>* Unique event entry index value.
log	Log event type.
trap	Trap event type.
log trap	Log and trap event type.
description *<description>*	Event entry description.
owner *<owner>*	Owner name to identify the entry.

Default No event is configured by default.

Mode Global Configuration

Example

```
awplus# configure terminal
awplus(config)# rmon event 299 log description cond3 owner
alfred

awplus# configure terminal
awplus(config)# no rmon event 299
```

Related Commands rmon alarm

show rmon alarm

Use this command to display the alarms and threshold configured for the RMON probe.

Note Only the alarms for switch port interfaces, not for VLAN interfaces, can be shown.

Syntax

```
show rmon alarm
```

Mode User Exec and Privileged Exec

Example

```
awplus# show rmon alarm
```

Related Commands rmon alarm

show rmon event

Use this command to display the events configured for the RMON probe.

Note Only the events for switch port interfaces, not for VLAN interfaces, can be shown.

Syntax

```
show rmon event
```

Mode User Exec and Privileged Exec

Output Figure 94-1: Example output from the **show rmon event** command

```
awplus#sh rmon event
 event Index = 787
       Description TRAP
        Event type log & trap
         Event community name gopher
       Last Time Sent = 0
       Owner  RMON_SNMP

 event Index = 990
       Description TRAP
        Event type trap
         Event community name teabo
       Last Time Sent = 0
       Owner  RMON_SNMP
```

Chapter 95: Triggers Introduction

Introduction 95.2
Trigger Facility 95.2
Configuring a Trigger 95.2
Troubleshooting Triggers 95.5

Introduction

This chapter provides information about the Trigger facility on this switch. For specific configuration examples, see Chapter 96, Triggers Configuration. For detailed descriptions of the commands used to configure triggers, see Chapter 97, Trigger Commands.

Trigger Facility

The Trigger facility provides a powerful mechanism for automatic and timed management of your device by automating the execution of commands in response to certain events. For example, you can use triggers to deactivate a service during the weekends, or to collect diagnostic information when the CPU usage is high.

A trigger is an ordered sequence of scripts that is executed when a certain event occurs. A script is a sequence of commands stored as a plaintext file on a file subsystem accessible to the device, such as Flash memory. Each trigger may reference multiple scripts and any script may be used by any trigger. When an event activates a trigger, the trigger executes the scripts associated with it in sequence. One script is executed completely before the next script begins. Various types of triggers are supported, each activated in a different way.

Configuring a Trigger

The following describes the general steps to configure a trigger. For specific configuration examples, see Chapter 96, Triggers Configuration.

Step 1: Create a configuration script

Create a configuration script with the commands you would like executed when the trigger conditions are met. To create the configuration script using the CLI, use the command:

```
awplus# edit [<filename>]
```

Alternatively, you can create a script on a PC then load it onto your device using the copy (URL) command.

Step 2: Enter the trigger configuration mode

You must be in the Global Configuration mode to reach the Trigger Configuration mode. Use the command:

```
awplus# configure terminal
```

To create a trigger, and enter its configuration mode, use the command:

```
awplus(config)# trigger <1-250>
```

Step 3: Set the trigger type

The trigger type determines how the trigger is activated. To set the trigger to activate:

« when a Secure Digital (SD) or Secure Digital High Capacity (SDHC) card is either inserted or removed, use the command:

```
awplus(config-trigger)# type card {in|out}
```

« when CPU usage reaches a certain level, use the command:

```
awplus(config-trigger)# type cpu <1-100> [up|down|any]
```

« when the link status of a particular interface changes, use the command:

```
awplus(config-trigger)# type interface <interface>
                        [up|down|any]
```

« when the RAM usage reaches a certain level, use the command:

```
awplus(config-trigger)# type memory <1-100> [up|down|any]
```

« periodically after a set number of minutes, use the command:

```
awplus(config-trigger)# type periodic <1-1440>
```

« when a ping poll identifies that a target device's status has changed, use the command:

```
awplus(config-trigger)# type ping-poll <1-100> {up|down}
```

« if your device reboots, use the command:

```
awplus(config-trigger)# type reboot
```

« when a stacking link goes up or down, use the command:

```
awplus(config-trigger)# type stack link {up|down}
```

« at a specific time of the day, use the command:

```
awplus(config-trigger)# type time <hh:mm>
```

Note that a combined limit of 10 triggers of the type periodic and type time can be configured. If you attempt to add more than 10 triggers the following error message is displayed:

```
% Cannot configure more than 10 triggers with the type time or
periodic
```

Step 4: Set the time and days that the trigger can activate on

By default triggers can activate at any time of the day, on all days. If you want your trigger to activate only during a specific time of the day, use the command:

```
awplus(config-trigger)# time {[after <hh:mm:ss>]
                        [before <hh:mm:ss>]}
```

If you want your trigger to activate only on a specific date, use the command:

```
awplus(config-trigger)# day <1-31> <month> <2000-2035>
```

If you want the trigger to activate only on specific days of the week, use the command:

```
awplus(config-trigger)# day <weekday>
```

Note that you can set either a specific date, or specific weekdays, but not both.

Step 5: Specify how often the trigger can activate

By default, triggers can activate an unlimited number of times, as long as the trigger conditions are met. To set a limit on the number of times a trigger can activate, use the command:

```
awplus(config-trigger)# repeat {forever|no|once|yes|
                        <1-4294967294>}
```

You device maintains two counters that track the number of times a trigger has activated. One counts the total number of times the trigger is activated and is only reset if the device restarts, or when the trigger is destroyed. The other counter tracks the permitted number of repetitions. To reset this counter, use the repeat command on page 97.6.

Step 6: Add the script to the trigger

You can add up to five scripts to the trigger. When a trigger is activated, it executes the scripts in sequence, with the lowest numbered script activated first. The first script runs to completion before the next script begins. To add a script, use the command:

```
awplus(config-trigger)# script <1-5> {<filename>}
```

Note that a script activated from a SD card trigger cannot be located on the SD or SDHC card. It must be located in Flash memory.

Step 7: Specify a description for the trigger

Specify a description for the trigger, so that you can easily identify the trigger in show commands and log output. Use the command:

```
awplus(config-trigger)# description <description>
```

Step 8: Verify the trigger's configuration

To check the configuration of the trigger, use the command:

```
awplus(config-trigger)# show trigger [<1-250>|counter|
                        full]
```

Troubleshooting Triggers

You can use the trigger diagnostic mode and trigger debugging to test your triggers and troubleshoot any issues.

Diagnostic mode is set per trigger. In this mode the trigger activates if its trigger conditions are met, but does not run any of its scripts. Your device generates a log message to indicate that the trigger was activated. To place a trigger in diagnostic mode, enter the trigger's configuration mode and use the command:

```
awplus(config-trigger)# test
```

To start debugging for triggers, use the command:

```
awplus(config-trigger)# debug trigger
```

This generates detailed messages about how your device is processing the trigger commands and activating the triggers.

Enabling and Disabling

Triggers are enabled by default. This allows the trigger to activate as soon as its trigger conditions are met. If you need to disable a trigger but do not want to delete the trigger, use the command:

```
awplus(config-trigger)# no active
```

To enable the trigger again, use the command:

```
awplus(config-trigger)# active
```

To delete the trigger, use the command:

```
awplus(config-trigger)# no trigger <1-250>
```

Chapter 96: Triggers Configuration

Introduction 96.2
Restrict Internet Access 96.2
Capture Unusual CPU and RAM Activity 96.4
See Daily Statistics 96.6
Turn Off Power to Port LEDs 96.7
Capture Show Output and Save to a SD Card 96.9
Load a Release File From a SD Card 96.10

Introduction

The chapter describes how to configure triggers to:

- Restrict Internet Access
- Capture Unusual CPU and RAM Activity
- See Daily Statistics
- Turn Off Power to Port LEDs
- Capture Show Output and Save to a SD Card

For more information about triggers, see Chapter 95, Triggers Introduction. For detailed descriptions of the commands used to configure triggers, see Chapter 97, Trigger Commands.

Restrict Internet Access

In the following configuration the ACME company wants to restrict its employees from accessing popular video sharing websites as this is causing bandwidth problems during work hours. The ACME company is happy for workers to access the site after work hours.

Employee PCs at ACME are on vlan2. Two triggers with associated scripts are needed:

- Trigger 1 activates at 8.30am and runs a script called shutdown.scp. This script adds commands to restrict access to the specified sites
- Trigger 2 activates at 5.30pm and runs the script called open.scp. This script removes the configuration specified by shutdown.scp

1. Create the shutdown.scp script

   Create a configuration script using Access Control List commands to restrict users on vlan2 from accessing the specific sites.

2. Create the open.scp script

   Create a script to remove the ACL configuration specified in the shutdown.scp file.

3. Configure trigger 1

   To create trigger 1, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 1
```

   Set the trigger to activate at 8:30am, by using the command:

```
awplus(config-trigger)# type time 08:30
```

   Set the trigger to activate on Monday, Tuesday, Wednesday, Thursday and Friday:

```
awplus(config-trigger)# day mon tue wed thur fri
```

   Add the script shutdown.scp to the trigger:

```
awplus(config-trigger)# script 1 shutdown.scp
```

Specify a helpful description, such as Stops access to video sharing sites. Use the command:

```
awplus(config-trigger)# description Stops access to video
                        sharing sites
```

Change to Global Configuration mode:

```
awplus(config-trigger)# exit
```

4. Configure trigger 2

   To create trigger 2, use the command:

   ```
   awplus(config)# trigger 2
   ```

   Set the trigger to activate at 5.30pm:

   ```
   awplus(config-trigger)# type time 17:30
   ```

   Set the trigger to activate on Monday, Tuesday, Wednesday, Thursday and Friday:

   ```
   awplus(config-trigger)# day mon tue wed thur fri
   ```

   Add the script open.scp to the trigger:

   ```
   awplus(config-trigger)# script 1 open.scp
   ```

   Specify a helpful description, such as Access allowed to video sharing sites. Use the command:

   ```
   awplus(config-trigger)# description Access allowed to video
                           sharing sites
   ```

5. Verify the configuration

   To check the configuration of the triggers, use the commands:

   ```
   awplus# show trigger 1

   awplus# show trigger 2
   ```

Capture Unusual CPU and RAM Activity

The following configuration allows you to troubleshoot high CPU or RAM usage by the device. It uses two triggers to capture show output, and places this output in a file.

- Trigger 3 activates the script cpu-usage.scp when CPU usage is over 90% and can activate up to 5 times
- Trigger 4 activates the script ram-usage.scp when RAM usage is over 95%, and can activate up to 10 times

1. Create the cpu-usage.scp configuration script

   Create a script with the appropriate show command:

   ```
   awplus# show cpu | redirect showcpu.txt
   ```

   The output of the show cpu command has been redirected into a file. It is not possible to display trigger script output on the terminal. Redirecting the command output to a file means it is available for later inspection.

   If the trigger activates on more than one occasion the contents of showcpu.txt will be overwritten with the latest output. To keep a full record for all activations of this trigger an ASH shell script can be added to the trigger to manage the output of the configuration script. For example:

   ```
   #!/bin/ash
   date >> showcpu_bkup.txt
   cat showcpu.txt >> showcpu_bkup.txt
   ```

   This script concatenates that date and time of activation and the contents of showcpu.txt onto the end of the backup file showcpu_bkup.txt in flash memory.

   Note that the files may grow large accumulating data and consume available flash memory.

2. Create the ram-usage.scp configuration script

   Create a script with the appropriate show command:

   ```
   awplus# show memory | redirect showmem.txt
   ```

   The output of the show memory command has been redirected into a file. It is not possible to display trigger script output on the terminal. Redirecting the command output to a file means it is available for later inspection.

   If the trigger activates on more than one occasion the contents of showcpu.txt will be overwritten with the latest output. To keep a full record for all activations of this trigger an ASH shell script can be added to the trigger to manage the output of the configuration script. For example:

   ```
   #!/bin/ash
   date >> showmem_bkup.txt
   cat showmem.txt >> showmem_bkup.txt
   ```

   This script concatenates that date and time of activation and the contents of showmem.scp onto the end of the backup file showmem_bkup.scp in flash memory.

   Note that the files may grow large accumulating data and consume available flash memory.

3. Configure trigger 3

   To create trigger 3, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 3
```

   Set the trigger to activate when CPU usage exceeds 80%:

```
awplus(config-trigger)# type cpu 90 up
```

   Add the script cpu-usage.scp to the trigger:

```
awplus(config-trigger)# script 1 cpu-usage.scp
```

   Return to Global Configuration mode:

```
awplus(config-trigger)# exit
```

4. Configure trigger 4

   To create trigger 4, use the command:

```
awplus(config)# trigger 4
```

   Set the trigger to activate when RAM usage exceeds 95%:

```
awplus(config-trigger)# type cpu 95 up
```

   Add the script cpu-usage.scp to the trigger:

```
awplus(config-trigger)# script 1 ram-usage.scp
```

5. Verify the configuration

   To check the configuration of the triggers, use the command:

```
awplus# show trigger 3
awplus# show trigger 4
```

See Daily Statistics

The ACME company has recently set up QoS on its traffic to give traffic different priorities to the ISP. ACME wants to assess how much traffic is dropped with the QoS bandwidths set over the next week. To do this, they want to generate an hourly report on QoS traffic on the first day that this is implemented.

- Trigger 5 activates the script qos-stats.scp every 60 minutes.
  The trigger is set to only activate during work hours.

1. Create the qos-stats.scp script

   Create a configuration script with the appropriate show commands. You can either create the configuration script using the CLI with the edit command or create a script on a PC then load it onto your device using the copy (URL) command.

2. Configure trigger 5

   To create trigger 5, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 5
```

   Set the trigger to activate periodically every 60 minutes:

```
awplus(config-trigger)# type periodic 60
```

   Set the trigger to activate only during the hours of 8:00am and 6:00pm:

```
awplus(config-trigger)# time after 8:00 before 18:00
```

   Add the script qos-stats.scp to the trigger:

```
awplus(config-trigger)# script 1 qos-stats.scp
```

3. Verify the configuration

   To check the configuration of the trigger, use the command:

```
awplus# show trigger 5
```

Turn Off Power to Port LEDs

The following configuration allows you to conserve power by using the eco-friendly feature to turn off power to the port LEDs during non-work hours.

- Trigger 6 activates at 5.30pm and runs a script called LEDoff.scp. This script adds commands to turn off power to all the port LEDs
- Trigger 7 activates at 8.30am and runs the script called LEDon.scp. This script removes the configuration specified by LEDoff.scp

1. Create the LEDoff.scp script

   Create a configuration script with the commands that are executed when the trigger conditions are met. You can either create the configuration script using the CLI with the edit command or create a script on a PC then load it onto your device using the copy (URL) command. The configuration script for this example is:

```
!
enable
configure terminal
ecofriendly led
exit
exit
!
```

2. Create the LEDon.scp script

   Create a script to remove the configuration specified in the LEDoff.scp file. The configuration script for this example is:

```
!
enable
configure terminal
no ecofriendly led
exit
exit
!
```

3. Configure trigger 6

   To create trigger 6, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 6
```

   Set the trigger to activate at 5:30pm, by using the command:

```
awplus(config-trigger)# type time 17:30
```

   Set the trigger to activate on Monday, Tuesday, Wednesday, Thursday and Friday:

```
awplus(config-trigger)# day mon tue wed thur fri
```

   Add the script LEDoff.scp to the trigger:

```
awplus(config-trigger)# script 1 powershutdown.scp
```

Specify a helpful description, such as Shutdown power to LEDs. Use the command:

```
awplus(config-trigger)# description Shutdown power to LEDs
```

Change to Global Configuration mode:

```
awplus(config-trigger)# exit
```

4. Configure trigger 7

   To create trigger 7, use the command:

   ```
   awplus(config)# trigger 9
   ```

   Set the trigger to activate at 8.30am:

   ```
   awplus(config-trigger)# type time 08:30
   ```

   Set the trigger to activate on Monday, Tuesday, Wednesday, Thursday and Friday:

   ```
   awplus(config-trigger)# day mon tue wed thur fri
   ```

   Add the script LEDon.scp to the trigger:

   ```
   awplus(config-trigger)# script 1 poweropen.scp
   ```

   Specify a helpful description, such as Turn on power to LEDs. Use the command:

   ```
   awplus(config-trigger)# description Turn on power to LEDs
   ```

5. Verify the configuration

   To check the configuration of the triggers, use the commands:

   ```
   awplus# show trigger 6
   awplus# show trigger 7
   ```

Capture Show Output and Save to a SD Card

The following configuration allows you to automatically capture output from the show tech-support command when a SD (or SDHC) card is inserted into the switch. It uses a script called by the SD card trigger to capture the show tech-support output and places this output in a file on the SD card.

- Trigger 8 activates the script shtech-sup.scp when an SD card is inserted in the switch

1. Create the shtech-sup.scp script

   Create a configuration script with the commands that are executed when the trigger conditions are met. You can either create the configuration script using the CLI with the edit command or create a script on a PC then load it onto your device using the copy (URL) command. The configuration script for this example is:

```
!
enable
show tech-support outfile card:support.txt.gz
exit
end
!
```

2. Configure trigger 8

   To create trigger 8, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 8
```

   Set the trigger to activate on the insertion of a SD card:

```
awplus(config-trigger)# type card in
```

   Add the script shtech-sup.scp to the trigger:

```
awplus(config-trigger)# script 1 shtech-sup.scp
```

3. Verify the configuration

   To check the configuration of the triggers, use the command:

```
awplus# show trigger 8
```

Load a Release File From a SD Card

The following configuration allows you to automatically load a release file from a SD (or SDHC) card into Flash memory when a card is inserted into the switch. It uses a script called by the SD card trigger to load the release file from the SD card.

Note that you can only specify that the release file is on a SD card if there is a backup release file already specified in Flash. See the boot system command for further information.

Caution Anyone with physical access to the switch and who knows the name of the release file loaded by the trigger could insert an SD card and overwrite the boot configuration in flash memory.

- Trigger 10 activates the script copy.scp when an SD card is inserted in the switch

1. Create the copy.scp script

   Create a configuration script with the commands that are executed when the trigger conditions are met. You can either create the configuration script using the CLI with the edit command or create a script on a PC then load it onto your device using the copy (URL) command. The configuration script for this example is:

```
!
enable
copy card flash x900-5.4.2.rel
wait 5
configure terminal
boot system x900-5.4.2.rel
exit
end
!
```

2. Configure trigger 10

   To create trigger 10, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 10
```

   Set the trigger to activate on the insertion of a SD card:

```
awplus(config-trigger)# type card in
```

   Add the script copy.scp to the trigger:

```
awplus(config-trigger)# script 1 copy.scp
```

   Specify a helpful description, such as Load a release file. Use the command:

```
awplus(config-trigger)# description Load a release file
```

After a SD card has been inserted in the switch, use the following two steps to check the trigger and current boot configuration details.

1. Verify the trigger configuration

   To check the configuration of the trigger, use the command:

```
awplus# show trigger 10
```

   Example output from this command is shown below:

```
awplus#show trigger 10
Trigger Configuration Details
-------------------------------------------------------------
Trigger ..................... 10
Description ................. Load a release file
Type and details ............ Card (in)
Days ........................ smtwtfs
After ....................... 00:00:00
Before ...................... 23:59:59
Active ...................... Yes
Test ........................ No
Trap ........................ Yes
Repeat ...................... Continuous
Modified .................... Wed Sep 15 16:25:33 2010
Number of activations ....... 1
Last activation ............. Wed Sep 15 16:26:49 2010

  1. copy.scp
  2. <not configured>
  3. <not configured>
  4. <not configured>
  5. <not configured>
-------------------------------------------------------------
```

2. Display the current boot configuration

   To display the current boot configuration, use the command:

```
awplus# show boot
```

   Example output from this command is shown below:

```
awplus#show boot
Boot configuration
-------------------------------------------------------------
Current software   : x900-5.4.2.rel
Current boot image : flash:/x900-5.4.2.rel
Backup  boot image : flash:/x900-5.4.2.rel
Default boot config: flash:/default.cfg
Current boot config: flash:/atplab.cfg (file exists)
Backup  boot config: flash:/default.cfg (file exists)
```

Command List

This chapter provides an alphabetical reference for commands used to configure Triggers. For more information, see Chapter 95, Triggers Introduction and Chapter 96, Triggers Configuration.

For information about modifying or redirecting the output from show commands to a file, see "Controlling "show" Command Output" on page 1.41.

active (trigger)

This command enables a trigger. This allows the trigger to activate when its trigger conditions are met.

The no variant of this command disables a trigger. While in this state the trigger cannot activate when its trigger conditions are met.

Syntax

```
active
no active
```

Mode Trigger Configuration

Examples To enable trigger 172, so that it can activate when its trigger conditions are met, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 172
awplus(config-trigger)# active
```

To disable trigger 182, preventing it from activating when its trigger conditions are met, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 182
awplus(config-trigger)# no active
```

Related Commands show trigger
trigger

day

This command specifies the days or date that the can trigger activate on. You can specify either:

- A specific date
- A specific day of the week
- A list of days of the week
- every day

By default, the trigger can activate on any day.

Syntax

```
day every-day
day <1-31> <month> <2000-2035>
day <weekday>
```

Parameter	Description
`every-day`	Sets the trigger so that it can activate on any day.
<1-31>	Day of the month the trigger is permitted to activate on.
<month>	Sets the month that the trigger is permitted to activate on. Valid keywords are: january, february, march, april, may, june, july, august, september, october, november, and december.
<2000-2035>	Sets the year that the trigger is permitted to activate in.
<weekday>	Sets the days of the week that the trigger can activate on. You can specify one or more week days in a space separated list. Valid keywords are: monday, tuesday, wednesday, thursday, friday, saturday, and sunday.

Mode Trigger Configuration

Usage For example trigger configurations that use the day command, see "Restrict Internet Access" on page 96.2 and "Turn Off Power to Port LEDs" on page 96.7.

Examples To permit trigger 55 to activate on the `1 Jun 2010`, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 55
awplus(config-trigger)# day 1 Jun 2010
```

To permit trigger 12 to activate on a Mondays, Wednesdays and Fridays, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 12
awplus(config-trigger)# day monday wednesday friday
```

Related Commands
show trigger
trigger

debug trigger

This command enables trigger debugging. This generates detailed messages about how your device is processing the trigger commands and activating the triggers.

The no variant of this command disables trigger debugging.

Syntax

```
debug trigger
```

```
no debug trigger
```

Mode

Privilege Exec

Examples

To start trigger debugging, use the command:

```
awplus# debug trigger
```

To stop trigger debugging, use the command:

```
awplus# no trigger
```

Related Commands

show trigger
test
trigger
undebug trigger

description (trigger)

This command adds an optional description to help you identify the trigger. This description is displayed in show command outputs and log messages.

The no variant of this command removes a trigger's description. The show command outputs and log messages stop displaying a description for this trigger.

Syntax

```
description <description>
no description
```

Parameter	Description
<description>	A word or phrase that uniquely identifies this trigger or its purpose. Valid characters are any printable character and spaces, up to a maximum of 40 characters.

Mode Trigger Configuration

Examples To give trigger 240 the description `daily status report`, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 240
awplus(config-trigger)# description daily status report
```

To remove the description from trigger `36`, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 36
awplus(config-trigger)# no description
```

Related Commands

show trigger
test
trigger

repeat

This command specifies the number of times that a trigger is permitted to activate. This allows you to specify whether you want the trigger to activate:

- only the first time that the trigger conditions are met
- a limited number of times that the trigger conditions are met
- an unlimited number of times

Once the trigger has reached the limit set with this command, the trigger remains in your configuration but cannot be activated. Use the repeat command again to reset the trigger so that it is activated when its trigger conditions are met.

By default, triggers can activate an unlimited number of times. To reset a trigger to this default, specify either yes or forever.

Syntax `repeat {forever|no|once|yes|<1-4294967294>}`

Parameter	Description
`yes|forever`	The trigger repeats indefinitely, or until disabled.
`no|once`	The trigger activates only once.
<1-4292967294>	The trigger repeats the set number of times.

Mode Trigger Configuration

Examples To allow trigger `21` to activate only once, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 21
awplus(config-trigger)# repeat no
```

To allow trigger `22` to activate an unlimited number of times whenever its trigger conditions are met, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 22
awplus(config-trigger)# repeat forever
```

To allow trigger `23` to activate only the first `10` times the conditions are met, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 23
awplus(config-trigger)# repeat 10
```

Related Commands show trigger
trigger

script

This command specifies one or more scripts that are to be run when the trigger activates. You can add up to five scripts to a single trigger.

The sequence in which the trigger runs the scripts is specified by the number you set before the name of the script file. One script is executed completely before the next script begins.

Scripts may be either ASH shell scripts, indicated by a .sh filename extension suffix, or AlliedWare Plus™ scripts, indicated by a .scp filename extension suffix. AlliedWare Plus™ scripts only need to be readable.

The no variant of this command removes one or more scripts from the trigger's script list. The scripts are identified by either their name, or by specifying their position in the script list. The all parameter removes all scripts from the trigger.

Syntax

```
script <1-5> {<filename>}
no script {<1-5>|<filename>|all}
```

Parameter	Description
<1-5>	The position of the script in execution sequence. The trigger runs the lowest numbered script first.
<filename>	The path to the script file.

Mode Trigger Configuration

Examples To configure trigger 71 to run the script flash:/cpu_trig.sh in position 3 when the trigger activates, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 71
awplus(config-trigger)# script 3 flash:/cpu_trig.sh
```

To configure trigger 99 to run the scripts flash:reconfig.scp, flash:cpu_trig.sh and flash:email.scp in positions 2, 3 and 5 when the trigger activates, use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 99
awplus(config-trigger)# script 2 flash:/reconfig.scp 3 flash:/
cpu_trig.sh 5 flash:/email.scp
```

To remove the scripts 1, 3 and 4 from trigger 71's script list, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 71
awplus(config-trigger)# no script 1 3 4
```

To remove the script flash:/cpu_trig.sh from trigger 71's script list, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 71
awplus(config-trigger)# no script flash:/cpu_trig.sh
```

To remove all the scripts from trigger 71's script list, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 71
awplus(config-trigger)# no script all
```

Related Commands show trigger
trigger

show running-config trigger

This command displays the current running configuration of the trigger utility.

Syntax

```
show running-config trigger
```

Mode Privileged Exec

Example To display the current configuration of the trigger utility, use the command:

```
awplus# show running-config trigger
```

Output Figure 97-1: Example output from the **show running-config trigger** command

```
trigger 1
 type card in
trigger 2
 type card out
!
```

Related Commands show trigger

show trigger

This command displays configuration and diagnostic information about the triggers configured on the device. Specify the show trigger command without any options to display a summary of the configuration of all triggers.

Syntax `show trigger [<1-250>|counter|full]`

Parameter	Description
<1-250>	Displays detailed information about a specific trigger, identified by its trigger ID.
`counter`	Displays statistical information about all triggers.
`full`	Displays detailed information about all triggers.

Mode Privileged Exec

Example To get summary information about all triggers, use the following command:

```
awplus# show trigger
```

Figure 97-2: Example output from the **show trigger** command

```
awplus#show trigger
TR# Type & Details       Name                  Ac Te Tr Repeat     #Scr Days/Date

```

Table 97-1: Parameters in the output of the **show trigger** command

Parameter	Description
`TR#`	Trigger identifier (ID).
`Type & Details`	The trigger type, followed by the trigger details in brackets.
`Name`	Descriptive name of the trigger configured with the description (trigger) command.
`Ac`	Whether the trigger is active (Y), or inactive (N).
`Te`	Whether the trigger is in test mode (Y) or not (N).
`Tr`	Whether or not the trigger is enabled to send SNMP traps. See the trap command.

Table 97-1: Parameters in the output of the **show trigger** command(cont.)

Parameter	Description
Repeat	Whether the trigger repeats continuously, and if not, the configured repeat count for the trigger. To see the number of times a trigger has activated, use the show trigger <1-250> command.
#Scr	Number of scripts associated with the trigger.
Days/Date	Days or date when the trigger may be activated. For the days options, the days are shown as a seven character string representing Sunday to Saturday. A hyphen indicates days when the trigger cannot be activated.

To display detailed information about trigger 3, use the command:

```
awplus# show trigger 3
```

Figure 97-3: Example output from the **show trigger** command for a specific trigger

```
awplus#show trigger 3

Table 97-2: Parameters in the output of the s**how trigger full** and **show trigger** commands for a specific trigger

Parameter	Description
Trigger	The ID of the trigger.
Description	Descriptive name of the trigger.
Type and details	The trigger type and its activation conditions.
Days	The days on which the trigger is permitted to activate.
Date	The date on which the trigger is permitted to activate. Only displayed if configured, in which case it replaces “Days”.
Active	Whether or not the trigger is permitted to activate.
Test	Whether or not the trigger is operating in diagnostic mode.
Trap	Whether or not the trigger is enabled to send SNMP traps.
Repeat	Whether the trigger repeats an unlimited number of times (Continuous) or for a set number of times. When the trigger can repeat only a set number of times, then the number of times the trigger has been activated is displayed in brackets.
Modified	The date and time of the last time that the trigger was modified.
Number of activations	Number of times the trigger has been activated since the last restart of the device.
Last activation	The date and time of the last time that the trigger was activated.
Number of scripts	How many scripts are associated with the trigger, followed by the names of the script files in the order in which they run.

To display counter information about all triggers use the command:

```
awplus# show trigger counter
```

Figure 97-5: Example output from the **show trigger counter** command

```
awplus#show trigger counter

-------------------------------------------------------
```

Table 97-3: Parameters in the output of the **show trigger counter** command

Parameter	Description
`Trigger activations`	Number of times a trigger has been activated.
`Time triggers activated today`	Number of times a time trigger has been activated today.
`Periodic triggers activated today`	Number of times a periodic trigger has been activated today.
`Interface triggers activated today`	Number of times an interface trigger has been activated today.
`Resource triggers activated today`	Number of times a CPU or memory resource trigger has been activated today.
`Ping-poll triggers activated today`	Number of times a ping-poll trigger has been activated today.

Related Commands trigger

test

This command puts the trigger into a diagnostic mode. In this mode the trigger may activate but when it does it will not run any of the trigger's scripts. A log message will be generated to indicate when the trigger has been activated.

The no variant of this command takes the trigger out of diagnostic mode, restoring normal operation. When the trigger activates the scripts associated with the trigger will be run, as normal.

Syntax

```
test
no test
```

Mode Trigger Configuration

Examples To put trigger 5 into diagnostic mode, where no scripts will be run when the trigger activates, use the commands:

```
                awplus# configure terminal
        awplus(config)# trigger 5
awplus(config-trigger)# test
```

To take trigger 205 out of diagnostic mode, restoring normal operation, use the commands:

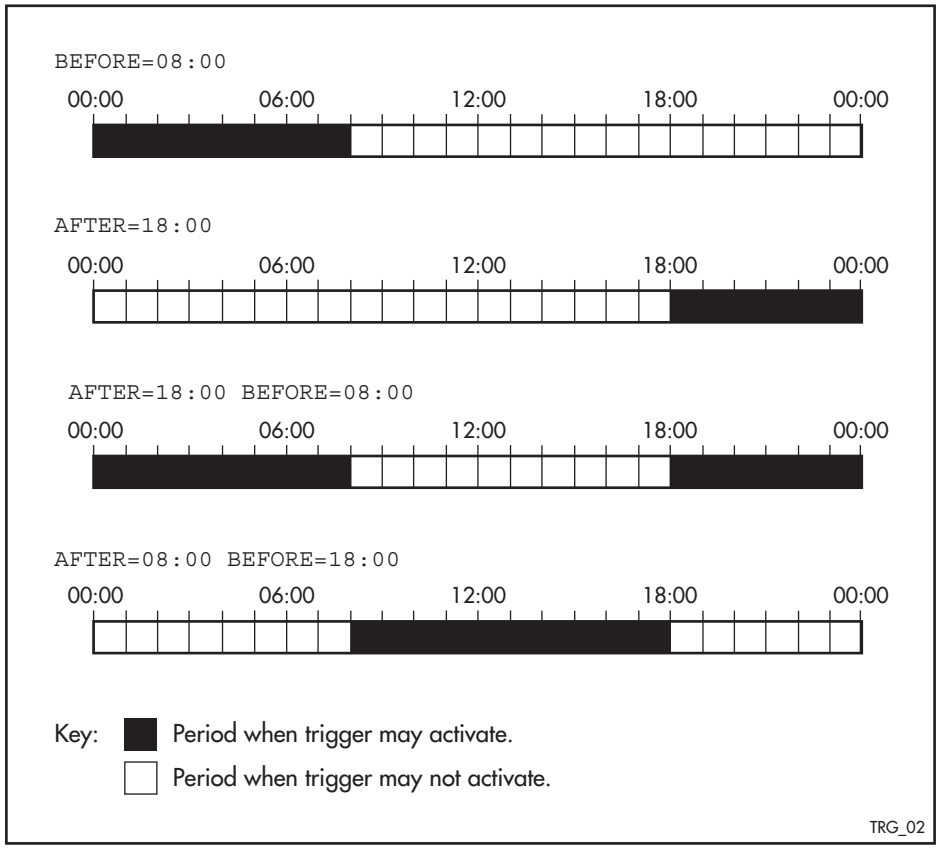
```
                awplus# configure terminal
        awplus(config)# trigger 205
awplus(config-trigger)# no test
```

Related Commands show trigger
trigger

time (trigger)

This command specifies the time of day when the trigger is permitted to activate. The after parameter specifies the start of a time period that extends to midnight during which trigger may activate. By default the value of this parameter is 00:00:00 (am); that is, the trigger may activate at any time. The before parameter specifies the end of a time period beginning at midnight during which the trigger may activate. By default the value of this parameter is 23:59:59; that is, the trigger may activate at any time. If the value specified for before is later than the value specified for after, a time period from "after" to "before" is defined, during which the trigger may activate. This command is not applicable to time triggers (type time).

The following figure illustrates how the before and after parameters operate.



Syntax `time {[after <hh:mm:ss>] [before <hh:mm:ss>]}`

Parameter	Description
`after` *<hh:mm:ss>*	The earliest time of day when the trigger may be activated.
`before` *<hh:mm:ss>*	The latest time of day when the trigger may be activated.

Mode Trigger Configuration

Usage For example trigger configurations that use the time (trigger) command, see "Restrict Internet Access" on page 96.2 and "Turn Off Power to Port LEDs" on page 96.7.

Examples To allow trigger `63` to activate between midnight and 10:30am, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 63
awplus(config-trigger)# time before 10:30:00
```

To allow trigger `64` to activate between 3:45pm and midnight, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 64
awplus(config-trigger)# time after 15:45:00
```

To allow trigger `65` to activate between 10:30am and 8:15pm, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 65
awplus(config-trigger)# time after 10:30:00 before 20:15:00
```

Related Commands show trigger
trigger

trap

This command enables the specified trigger to send SNMP traps.

Use the no variant of this command to disable the sending of SNMP traps from the specified trigger.

Syntax

```
trap
no trap
```

Default SNMP traps are enabled by default for all defined triggers.

Mode Trigger Configuration

Usage You must configure SNMP before using traps with triggers. See the following SNMP chapters:
Chapter 87, SNMP Introduction
Chapter 88, SNMP Commands
Chapter 89, SNMP MIBs

Since SNMP traps are enabled by default for all defined triggers, a common usage will be for the no variant of this command to disable SNMP traps from a specified trap if the trap is only periodic. Refer in particular to AT-TRIGGER-MIB for further information about the relevant SNMP MIB.

Examples To enable SNMP traps to be sent from trigger 5, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 5
awplus(config-trigger)# trap
```

To disable SNMP traps being sent from trigger 205, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 205
awplus(config-trigger)# no trap
```

Related Commands
trigger
show trigger

trigger

This command is used to access the Trigger Configuration mode for the specified trigger. Once Trigger Configuration mode has been entered the trigger type information can be configured and the trigger scripts and other operational parameters can be specified. At a minimum the trigger type information must be specified before the trigger can become active.

The no variant of this command removes a specified trigger and all configuration associated with it.

Syntax

```
trigger <1-250>
no trigger <1-250>
```

Parameter	Description
<*1-250*>	A trigger ID.

Mode Global Configuration

Examples To enter trigger configuration mode for trigger `12` use the command:

```
awplus# trigger 12
```

To completely remove all configuration associated with trigger `12`, use the command:

```
awplus# no trigger 12
```

Related Commands

show trigger
trigger activate

trigger activate

This command is used to manually activate a specified trigger from the Privileged Exec mode, which has been configured with the trigger command from the Global Configuration mode.

Syntax `trigger activate <1-250>`

Parameter	Description
<*1-250*>	A trigger ID.

Mode Privileged Exec

Usage This command manually activates a trigger without the normal trigger conditions being met.

The trigger is activated even if it is configured as inactive. The scripts associated with the trigger will be executed even if the trigger is in the diagnostic test mode.

Triggers activated manually do not have their repeat counts decremented or their 'last triggered' time updated, and do not result in updates to the '[type] triggers today' counters.

Example To manually activate trigger `12` use the command:

```
awplus# trigger activate 12
```

Related Commands show trigger
trigger

type card

Use this command to configure a trigger that activates on either the removal or the insertion of a Secure Digital (SD) or Secure Digital High Capacity (SDHC) card.

Syntax `type card {in|out}`

Parameter	Description
`in`	Trigger activates on insertion of a card.
`out`	Trigger activates on removal of a card.

Mode Trigger Configuration

Usage Card triggers cannot execute script files from a card.

In a VCStack configuration, card triggers are activated on the master for either the insertion or removal of a card on the master only.

For example trigger configurations that use the type card command, see "Capture Show Output and Save to a SD Card" on page 96.9 .

Examples To configure `trigger 1` to activate on the insertion of a card, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 1
awplus(config-trigger)# type card in
```

Related Commands
trigger
show running-config trigger
show trigger

type cpu

This command configures a trigger to activate based on CPU usage level. Selecting the up option causes the trigger to activate when the CPU usage exceeds the specified usage level. Selecting the down option causes the trigger to activate when CPU usage drops below the specified usage level. Selecting any causes the trigger to activate in both situations. The default is any.

Syntax `type cpu <1-100> [up|down|any]`

Parameter	Description
`<1-100>`	The percentage of CPU usage at which to trigger.
`up`	Activate when CPU usage exceeds the specified level.
`down`	Activate when CPU usage drops below the specified level
`any`	Activate when CPU usage passes the specified level in either direction

Mode Trigger Configuration

Usage For an example trigger configuration that uses the type cpu command, see "Capture Unusual CPU and RAM Activity" on page 96.4.

Examples To configure trigger `28` to be a CPU trigger that activates when CPU usage exceeds 80% use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 28
awplus(config-trigger)# type cpu 80 up
```

To configure trigger `5` to be a CPU trigger that activates when CPU usage either rises above or drops below 65%, use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 5
awplus(config-trigger)# type cpu 65
```

or

```
awplus# configure terminal
awplus(config)# trigger 5
awplus(config-trigger)# type cpu 65 any
```

Related Commands show trigger
trigger

type interface

This command configures a trigger to activate based on the link status of an interface. The trigger can be activated when the interface becomes operational by using the up option, or when the interface closes by using the down option. The trigger can also be configured to activate when either one of these events occurs by using the any option.

Syntax `type interface <interface> [up|down|any]`

Parameter	Description
`<interface>`	Interface name. This can be the name of a switch port, an eth-management port, or a VLAN.
`up`	Activate when interface becomes operational.
`down`	Activate when the interface closes.
`any`	Activate when any interface link status event occurs.

Mode Trigger Configuration

Example To configure trigger `19` to be an interface trigger that activates when `port1.0.2` becomes operational, use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 19
awplus(config-trigger)# type interface port1.0.2 up
```

Related Commands
show trigger
trigger

type memory

This command configures a trigger to activate based on RAM usage level. Selecting the up option causes the trigger to activate when memory usage exceeds the specified level. Selecting the down option causes the trigger to activate when memory usage drops below the specified level. Selecting any causes the trigger to activate in both situations. The default is any.

Syntax

```
type memory <1-100> [up|down|any]
```

Parameter	Description
<1-100>	The percentage of memory usage at which to trigger.
up	Activate when memory usage exceeds the specified level.
down	Activate when memory usage drops below the specified level.
any	Activate when memory usage passes the specified level in either direction.

Mode

Trigger Configuration

Examples

To configure trigger `12` to be a memory trigger that activates when memory usage exceeds 50% use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 12
awplus(config-trigger)# type memory 50 up
```

To configure trigger `40` to be a memory trigger that activates when memory usage either rises above or drops below 65%, use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 40
awplus(config-trigger)# type memory 65
```

or

```
awplus# configure terminal
awplus(config)# trigger 40
awplus(config-trigger)# type memory 65 any
```

Related Commands

show trigger
trigger

type periodic

This command configures a trigger to be activated at regular intervals. The time period between activations is specified in minutes.

Syntax `type periodic <1-1440>`

Parameter	Description
<1-1440>	The number of minutes between activations.

Mode Trigger Configuration

Usage A combined limit of 10 triggers of the type periodic and time can be configured. If you attempt to add more than 10 triggers the following error message is displayed:

```
% Cannot configure more than 10 triggers with the type time or
periodic
```

For an example trigger configuration that uses the type periodic command, see "See Daily Statistics" on page 96.6.

Example To configure trigger `44` to activate periodically at `10` minute intervals use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 44
awplus(config-trigger)# type periodic 10
```

Related Commands
show trigger
trigger

type ping-poll

This command configures a trigger that activates when Ping Polling identifies that a target device's status has changed. This allows you to run a configuration script when a device becomes reachable or unreachable.

Syntax `type ping-poll <1-100> {up|down}`

Parameter	Description
<1-100>	The ping poll ID.
`up`	The trigger activates when ping polling detects that the target is reachable.
`down`	The trigger activates when ping polling detects that the target is unreachable.

Mode Trigger Configuration

Example To configure trigger `106` to activate when ping poll `12` detects that its target device is now unreachable, use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 106
awplus(config-trigger)# type ping-poll 12 down
```

Related Commands show trigger
trigger

type reboot

This command configures a trigger that activates when your device is rebooted.

Syntax `type reboot`

Mode Trigger Configuration

Example To configure trigger `32` to activate when your device reboots, use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 32
awplus(config-trigger)# type reboot
```

Related Commands show trigger
trigger

type stack disabled-master

This command (configured to the stack) configures a trigger to activate on a stack member if it becomes the disabled master.

A disabled master has the same configuration as the active master, but has all its links shutdown.

Although this command could activate any trigger script, the intention here is that the script will reactivate the links from their previously shutdown state, to enable the user to manage the switch. An appropriate trigger script must already exist that will apply the no shutdown command on page 11.13 on the deactivated links.

Caution

It is important that any ports that are configured as trunked ports across master and stack members are disabled at their stack member termination when operating in the fallback configuration. Otherwise, the trunked ports will not function correctly on the switch that is connected downstream.

If the stack virtual-mac command on page 103.38 command is enabled, the stack uses a virtual MAC address. The stack will always use this MAC address and the new elected master will still retain the originally configured virtual MAC address. If the stack virtual-mac command is disabled, the stack will use the MAC address of the current master. If the stack master fails, the stack MAC address changes to reflect the new master's MAC address. See "Fixed or Virtual MAC Addressing" on page 102.13 for information on virtual MAC addresses.

Syntax

```
type stack disabled-master
```

Mode

Trigger Configuration

Examples

To configure trigger `82` to activate on a device if it becomes the disabled master, use the commands:

Command	Description
`awplus#` `configure terminal`	Enter the Global Configuration mode
`awplus(config)#` `trigger 82`	Enter the Trigger Configuration mode for trigger 82
`awplus(config-trigger)#` `type stack disabled master`	Sets the type of trigger
`awplus(config-trigger)#` `script 1 flash:/disabled.scp`	
`awplus(config-trigger)#` `exit`	

Related Commands

stack disabled-master-monitoring
trigger
type stack master-fail
type stack member
type stack link

type stack master-fail

This command (configured to the stack) initiates the action of a pre-configured trigger to occur when the stack enters the fail-over state.

Syntax `type stack master-fail`

Mode Trigger Configuration

Example To configure trigger `86` to activate when stack master fail-over event occurs, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 86
awplus(config-trigger)# type stack master-fail
```

Related Commands
stack disabled-master-monitoring
trigger
type stack disabled-master
type stack member
type stack link

type stack member

This command (configured to the stack) initiates the action of a pre-configured trigger to occur when a switch either joins or leaves the stack.

Syntax `type stack member {join|leave}`

Parameter	Description
`join`	Neighbor join event
`leave`	Neighbor leave event

Mode Trigger Configuration

Example To configure a pre-configured trigger number `86` to activate when a new switch joins the stack Note that the number `86` has no particular significance; you can assign any (previously created) numbered trigger

```
awplus# configure terminal
awplus(config)# trigger 86
awplus(config-trigger)# type stack member join
```

Related Commands
trigger
type stack master-fail
type stack link

type stack link

This command (configured to the stack) initiates the action of a pre-configured trigger to occur when a stacking link is either activated or deactivated.

Syntax

```
type stack link {up|down}
```

Parameter	Description
up	Stack link up event
down	Stack link down event

Mode Trigger Configuration

Example To configure trigger 86 to activate when the stack link down event occurs, use the commands:

```
awplus# configure terminal
awplus(config)# trigger 86
awplus(config-trigger)# type stack link down
```

Related Commands

show trigger
trigger
type stack master-fail

type time

This command configures a trigger that activates at a specified time of day.

Syntax `type time <hh:mm>`

Parameter	Description
<hh:mm>	The time to activate the trigger.

Mode Trigger Configuration

Usage A combined limit of 10 triggers of the type time and type periodic can be configured. If you attempt to add more than 10 triggers the following error message is displayed:

```
% Cannot configure more than 10 triggers with the type time or
periodic
```

Example To configure trigger `86` to activate at `15:53`, use the following commands:

```
awplus# configure terminal
awplus(config)# trigger 86
awplus(config-trigger)# type time 15:53
```

Related Commands show trigger
trigger

undebug trigger

This command applies the functionality of the no debug trigger command.

Chapter 98: Ping Polling Introduction and Configuration

Introduction 98.2
How Ping Polling Works 98.2
Configuring Ping Polling 98.4
- Creating a Polling Instance 98.4
- Customizing a Polling Instance 98.5
- Troubleshooting Ping Polling 98.6

Interaction with Other Protocols 98.7

Introduction

Ping polling lets your device regularly check whether it can reach other hosts on a network. It works by sending ICMP Echo Requests to a host and waiting for replies sent back. If ping polling indicates that a host's status has changed, then your device can respond to the new status. When a host is unreachable, ping polling continues monitoring the host's reachability.

You can configure triggers to activate when ping polling determines that the host's status has changed. For example, you could configure a trigger to run a script that opens and configures an alternative link if the host at the other end of a preferred link becomes unavailable. You could then configure a second trigger to run a script that automatically returns traffic to the preferred link as soon as it is available again.

How Ping Polling Works

To determine a host's reachability, your device regularly sends ICMP Echo Request packets ("pings") to the host. As long as your device receives ping responses from the host, it considers the host to be reachable. If your device does not receive a reply to a set number of ICMP Echo Requests, it considers that the host is unreachable. It continues to try to ping the device, at an increased rate. After it receives a set number of responses, it considers the device to be reachable again.

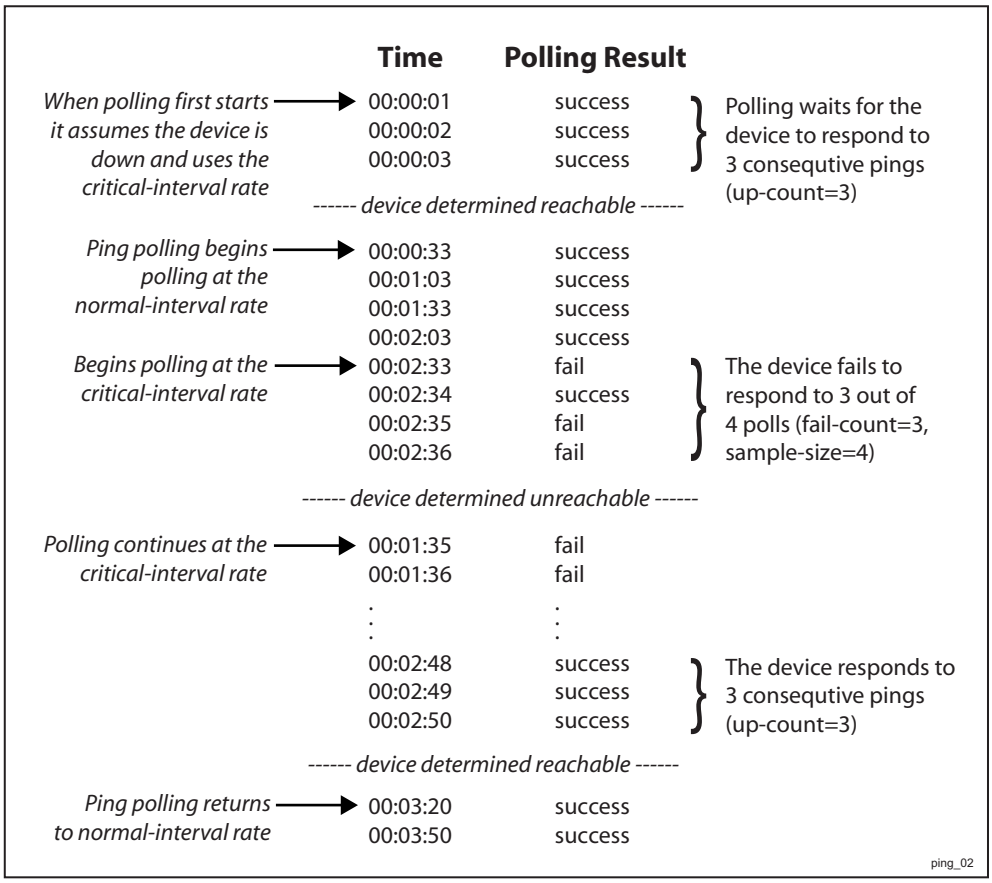
By default, a polling instance sends a ping every 30 seconds as long as it is receiving replies. The frequency of this polling is controlled by the normal-interval command. When a reply is not received, the polling instance increases the frequency at which it polls the device. This frequency is controlled by the critical-interval command, and by default, is set to send a packet every one second. It maintains this higher rate of polling until it has received sufficient consecutive replies.

The polling instance determines whether a device is reachable or unreachable based on the settings of the fail-count, sample-size, and up-count commands. To determine whether a device is reachable, the polling instance counts the number of failed pings within a set sample size. The sample size is set by the sample-size command, and by default is 5 ping responses. Within the sample size, the number of failed pings that means that the device is down is set by the fail-count command. By default this is set to 5. Once a polling instance has determined that a device is unreachable, it must receive a set number of consecutive replies before it changes the device's status back to reachable. This number is configured with the up-count command.

The following figure illustrates a polling instance where the device becomes unreachable, then reachable. It uses this configuration:

```
awplus(config-ping-poll)# fail-count 4
awplus(config-ping-poll)# sample-size 5
awplus(config-ping-poll)# up-count 3
awplus(config-ping-poll)# critical-interval 1
awplus(config-ping-poll)# normal-interval 30
```

Figure 98-1: Interaction between states and parameters for ping polling



On some operating systems, some servers may respond to a ping even if no other functionality is available, and therefore remain in an Up state while malfunctioning.

Responding to status changes

To configuring your device to determine and respond to changes in a device's reachability, you will need to:

- create a polling instance to periodically ping the device
- create scripts to run when the device becomes unreachable and when it becomes reachable again
- configure triggers to run these scripts

To set a trigger to activate when a device's status changes, its trigger type must be ping-poll. This is with the following command in the trigger's configuration mode:

```
awplus(config-trigger)# type ping-poll <1-100> {up|down}
```

where up activates the trigger when the device is reachable, and down activates the trigger when the device is unreachable.

If you use triggers to open a backup link to a remote device in the event of the primary link failing (rather than the remote device failing), the backup link and primary link must point to different IP addresses on the remote device. Otherwise, when the backup link points to the IP address that your device is polling, your device receives ping replies through the backup link, considers the device to be reachable again, and attempts to reopen the primary link instead of using the backup link. See Chapter 95, Triggers Introduction for more information about configuring Triggers with Ping Polling.

Configuring Ping Polling

This section contains:

- Creating a Polling Instance
  This explains how to quickly create a polling instance using the ping polling defaults.
- Customizing a Polling Instance
  This explains how to customize a ping poll and explains the other ping poll commands.
- Troubleshooting Ping Polling
  This explains how to use the debugging and monitoring commands for ping polling.

Creating a Polling Instance

The Ping Polling feature in the AlliedWare Plus™ OS allows you to easily configure polling instances with a minimum of commands. To configure a ping poll suitable for most network situations:

1. Create a polling instance by using the command:

```
awplus(config)# ping-poll <1-100>
```

   The range <1-100> identifies the polling instance in the trigger commands and in other ping poll commands. Your device can poll up to 100 IP addresses at once.

2. Set the IP address of the device you are polling by using the command:

```
awplus(config-ping-poll)# ip {<ip-address>|<ipv6-address>}
```

3. Enable the polling instance by using the command:

```
awplus(config-ping-poll)# active
```

4. If desired, set an optional description to identify the polling instance, by using the command:

```
awplus(config-ping-poll)# description <description>
```

You do not need to configure any other commands for most networks, because convenient defaults exist for all other ping poll settings. The following table summarizes the default configuration created.

Command	Default
Critical-interval	1 second
Fail-count	5
Length	32 bytes
Normal-interval	30 seconds
Sample-size	5

Command(cont.)	Default(cont.)
Source-ip	The IP address of the interface from which the ping packets are transmitted
Time-out	1 second
Up-count	30

Customizing a Polling Instance

Once you've created a polling instance using the ping-poll and ip (ping-polling) command, you may wish to customize the polling instance for your network.

Packet size

If you find that larger packet types in your network are not reaching the polled device while smaller ones such as ping do, you can increase the data bytes included in the ping packets sent by the polling instance. This encourages the polling instance to change the device's status to unreachable when packet of the size you are interested in are being dropped. To change the number of bytes sent in the data portion of the ping packets, use the command:

```
awplus(config-ping-poll)# length <4-1500>
```

Response timeout

The polling instance determines that a device hasn't responded to a ping if one second elapses without a response to the ping. In networks where ping packets have a low priority, you may need to set the allowed response time to a longer time period. To change this, use the command:

```
awplus(config-ping-poll)# timeout <1-30>
```

Polling frequency

By default, a polling instance polls a reachable device every 30 seconds. You can change this by using the command:

```
awplus(config-ping-poll)# normal-interval <1-65536>
```

Once the polling instance has determined that a ping has failed, it starts polling the device at the frequency set as the critical interval—by default, one second. To change the frequency set by the critical interval, use the command:

```
awplus(config-ping-poll)# critical-interval <1-65536>
```

The critical interval enables the polling instance to quickly observe changes in the state of the device, and should be set to a much lower value than the normal interval.

Configuring when the device's status changes

The number of pings that the polling instance examines to consider a change in state is controlled by the interaction of the sample-size, fail-count, and up-count commands. See "How Ping Polling Works" on page 98.2 for an example showing this interaction.

To determine whether a device is reachable, the polling instance counts the number of failed pings within a sample of a set size. The sample size is 5 pings by default. To change the sample size, use the command:

```
awplus(config-ping-poll)# sample-size <1-100>
```

To change the number of failed pings that the sample must have, use the command:

```
awplus(config-ping-poll)# fail-count <1-100>
```

If the sample size and fail count are the same, the unanswered pings must be consecutive. If the sample size is greater than the fail count, a device that does not always reply to pings may be declared unreachable.

The upcount is the number of consecutive pings that must be answered for the polling instance to consider the device reachable again. To change this from the default of 30, use the command:

```
awplus(config-ping-poll)# up-count <1-100>
```

Checking the configuration

To check the settings and status of the polling instance, use the command:

```
awplus(config-ping-poll)# show ping-poll [<1-100>|state {up|
                          down}] [brief]
```

Troubleshooting Ping Polling

To disable a polling instance, use the command:

```
awplus(config-ping-poll)# no active
```

The polling instance no longer sends ICMP echo requests to the polled device and the counters for this polling instance are reset.

To clear the counters and change the status of a device to unreachable, enter the Privileged Exec mode and use the command:

```
awplus# clear ping-poll {<1-100>|all}
```

The polling instance changes to the polling frequency specified with the critical-interval command. The device status changes to reachable once the device responses have reached the up-count.

To start debugging for ping polling, use the command:

```
awplus# debug ping-poll <1-100>
```

Interaction with Other Protocols

Ping polling does not work if the polled host, your device, or any intermediate routers or switches are configured to drop ICMP Echo Requests and Replies.

Ping and Traceroute

Ping and Traceroute are not affected by ping polling. You can enter ping and trace commands at any time and independent of the polling.

Chapter 99: Ping-Polling Commands

Command List 99.2
active (ping-polling) 99.3
clear ping-poll 99.4
critical-interval 99.5
debug ping-poll 99.6
description (ping-polling) 99.7
fail-count 99.8
ip (ping-polling) 99.9
length (ping-poll data) 99.10
normal-interval 99.11
ping-poll 99.12
sample-size 99.13
show counter ping-poll 99.14
show ping-poll 99.16
source-ip 99.20
timeout (ping polling) 99.21
up-count 99.22
undebug ping-poll 99.22

Command List

This chapter provides an alphabetical reference for commands used to configure Ping Polling. For more information, see Chapter 98, Ping Polling Introduction and Configuration.

For information about modifying or redirecting the output from show commands to a file, see "Controlling "show" Command Output" on page 1.41.

Table 99-1: The following table lists the default values when configuring a ping poll.

Default	Value
Critical-interval	1 second
Description	No description
Fail-count	5
Length	32 bytes
Normal-interval	30 seconds
Sample-size	5
Source-ip	The IP address of the interface from which the ping packets are transmitted
Time-out	1 second
Up-count	30

active (ping-polling)

This command enables a ping-poll instance. The polling instance sends ICMP echo requests to the device with the IP address specified by the ip (ping-polling) command.

By default, polling instances are disabled. When a polling instance is enabled, it assumes that the device it is polling is unreachable.

The no variant of this command disables a ping-poll instance. The polling instance no longer sends ICMP echo requests to the polled device. This also resets all counters for this polling instance.

Syntax

```
active
no active
```

Mode Ping-Polling Configuration

Examples To activate the ping-poll instance 43, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 43
awplus(config-ping-poll)# active
```

To disable the ping-poll instance 43 and reset its counters, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 43
awplus(config-ping-poll)# no active
```

Related Commands

debug ping-poll
ip (ping-polling)
ping-poll
show ping-poll

clear ping-poll

This command resets the specified ping poll, or all ping poll instances. This clears the ping counters, and changes the status of polled devices to unreachable. The polling instance changes to the polling frequency specified with the critical-interval command. The device status changes to reachable once the device responses have reached the up-count.

Syntax

```
clear ping-poll {<1-100>|all}
```

Parameter	Description
<1-100>	A ping poll ID number. The specified ping poll instance has its counters cleared, and the status of the device it polls is changed to unreachable.
`all`	Clears the counters and changes the device status of all polling instances.

Mode

Privileged Exec

Examples

To reset the ping poll instance 12, use the command:

```
awplus# clear ping-poll 12
```

To reset all ping poll instances, use the command:

```
awplus# clear ping-poll all
```

Related Commands

active (ping-polling)
ping-poll
show ping-poll

critical-interval

This command specifies the time period in seconds between pings when the polling instance has not received a reply to at least one ping, and when the device is unreachable.

This command enables the device to quickly observe changes in state, and should be set to a much lower value than the normal-interval command.

The no variant of this command sets the critical interval to the default of one second.

Syntax

```
critical-interval <1-65536>
no critical-interval
```

Parameter	Description
<1-65536>	Time in seconds between pings, when the device has failed to a ping, or the device is unreachable.

Default The default is 1 second.

Mode Ping-Polling Configuration

Examples To set the critical interval to 2 seconds for the ping-polling instance 99, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 99
awplus(config-ping-poll)# critical-interval 2
```

To reset the critical interval to the default of one second for the ping-polling instance 99, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 99
awplus(config-ping-poll)# no critical-interval
```

Related Commands

fail-count
normal-interval
sample-size
show ping-poll
timeout (ping polling)
up-count

debug ping-poll

This command enables ping poll debugging for the specified ping-poll instance. This generates detailed messages about ping execution.

The no variant of this command disables ping-poll debugging for the specified ping-poll.

Syntax

```
debug ping-poll <1-100>
no debug ping-poll {<1-100>|all}
```

Parameter	Description
<1-100>	A unique ping poll ID number.
`all`	Turn off all ping-poll debugging.

Mode Privileged Exec

Examples To enable debugging for ping-poll instance 88, use the command:

```
awplus# debug ping-poll 88
```

To disable all ping poll debugging, use the command:

```
awplus# no debug ping-poll all
```

To disable debugging for ping-poll instance 88, use the command:

```
awplus# no debug ping-poll 88
```

Related Commands

active (ping-polling)
clear ping-poll
ping-poll
show ping-poll
undebug ping-poll

description (ping-polling)

This command specifies a string to describe the ping-polling instance. This allows the ping-polling instance to be recognized easily in show commands. Setting this command is optional.

By default ping-poll instances do not have a description.

Use the no variant of this command to delete the description set.

Syntax

```
description <description>
no description
```

Parameter	Description
<description>	The description of the target. Valid characters are any printable character and spaces. There is no maximum character length.

Mode Ping-Polling Configuration

Examples To add the text “Primary Gateway” to describe the ping-poll instance 45, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 45
awplus(config-ping-poll)# description Primary Gateway
```

To delete the description set for the ping-poll instance 45, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 45
awplus(config-ping-poll)# no description
```

Related Commands

ping-poll
show ping-poll

fail-count

This command specifies the number of pings that must be unanswered, within the total number of pings specified by the sample-size command, for the ping-polling instance to consider the device unreachable.

If the number set by the sample-size command and the fail-count commands are the same, then the unanswered pings must be consecutive. If the number set by the sample-size command is greater than the number set by the fail-count command, then a device that does not always reply to pings may be declared unreachable.

The no variant of this command resets the fail count to the default.

Syntax

```
fail-count <1-100>
no fail-count
```

Parameter	Description
<1-100>	The number of pings within the sample size that a reachable device must fail to respond to before it is classified as unreachable.

Default The default is 5.

Mode Ping-Polling Configuration

Examples To specify the number of pings that must fail within the sample size to determine that a device is unreachable for ping-polling instance 45, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 45
awplus(config-ping-poll)# fail-count 5
```

To reset the fail-count to its default of 5 for ping-polling instance 45, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 45
awplus(config-ping-poll)# no fail-count
```

Related Commands

critical-interval
normal-interval
ping-poll
sample-size
show ping-poll
timeout (ping polling)
up-count

ip (ping-polling)

This command specifies the IPv4 address of the device you are polling.

Syntax `ip {<ip-address>|<ipv6-address>}`

Parameter	Description
<ip-address>	An IPv4 address in dotted decimal notation `A.B.C.D`
<ipv6-address>	An IPv6 address in hexadecimal notation `X:X::X:X`

Mode Ping-Polling Configuration

Examples To set ping-poll instance 5 to poll the device with the IP address `192.168.0.1`, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 5
awplus(config-ping-poll)# ip 192.168.0.1
```

To set ping-poll instance 10 to poll the device with the IPv6 address `2001:db8::`, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 10
awplus(config-ping-poll)# ip 2001:db8::
```

Related Commands
ping-poll
source-ip
show ping-poll

length (ping-poll data)

This command specifies the number of data bytes to include in the data portion of the ping packet. This allows you to set the ping packets to a larger size if you find that larger packet types in your network are not reaching the polled device, while smaller packets are getting through. This encourages the polling instance to change the device's status to unreachable when the network is dropping packets of the size you are interested in.

The no variant of this command resets the data bytes to the default of 32 bytes.

Syntax

```
length <4-1500>
no length
```

Parameter	Description
<4-1500>	The number of data bytes to include in the data portion of the ping packet.

Default The default is 32.

Mode Ping-Polling Configuration

Examples To specify that ping-poll instance 12 sends ping packet with a data portion of 56 bytes, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 12
awplus(config-ping-poll)# length 56
```

To reset the number of data bytes in the ping packet to the default of 32 bytes for ping-poll instance 3, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 3
awplus(config-ping-poll)# ping-poll 3
```

Related Commands

ping-poll
show ping-poll

normal-interval

This command specifies the time period between pings when the device is reachable.

The no variant of this command resets the time period to the default of 30 seconds.

Syntax

```
normal-interval <1-65536>
no normal-interval
```

Parameter	Description
<1-65536>	Time in seconds between pings when the target is reachable.

Default The default is 30 seconds.

Mode Ping-Polling Configuration

Examples To specify a time period of 60 seconds between pings when the device is reachable for ping-poll instance 45, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 45
awplus(config-ping-poll)# normal-interval 60
```

To reset the interval to the default of 30 seconds for ping-poll instance 45, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 45
awplus(config-ping-poll)# no normal-interval
```

timeout (ping polling)
up-count

ping-poll

This command enters the ping-poll configuration mode. If a ping-poll exists with the specified number, then this command enters its configuration mode. If no-ping poll exists with the specified number, then this command creates a new ping poll with this ID number.

To configure a ping-poll, create a ping poll using this command, and use the ip (ping-polling) command to specify the device you want the polling instance to poll. It is not necessary to specify any further commands unless you want to change a command's default.

The no variant of this command deletes the specified ping poll.

Syntax

```
ping-poll <1-100>
no ping-poll <1-100>
```

Parameter	Description
<1-100>	A unique ping poll ID number.

Mode Global Configuration

Examples To create ping-poll instance 3 and enter ping-poll configuration mode, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 3
awplus(config-ping-poll)#
```

To delete ping-poll instance 3, use the commands:

```
awplus# configure terminal
awplus(config)# no ping-poll 3
```

Related Commands

length (ping-poll data)
show ping-poll
source-ip

sample-size

This command sets the total number of pings that the polling instance inspects when determining whether a device is unreachable. If the number of pings specified by the fail-count command go unanswered within the inspected sample, then the device is declared unreachable.

If the numbers set in this command and fail-count command are the same, the unanswered pings must be consecutive. If the number set by this command is greater than that set with the fail-count command, a device that does not always reply to pings may be declared unreachable.

You cannot set this command's value lower than the fail-count value.

The polling instance uses the number of pings specified by the up-count command to determine when a device is reachable.

The no variant of this command resets this command to the default.

Syntax

```
sample-size <1-100>
no sample size
```

Parameter	Description
<1-100>	Number of pings that determines critical and up counts.

Default The default is 5.

Mode Ping-Polling Configuration

Examples To set the sample-size to 50 for ping-poll instance 43, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 43
awplus(config-ping-poll)# sample-size 50
```

To reset sample-size to the default of 5 for ping-poll instance 43, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 43
awplus(config-ping-poll)# no sample-size
```

show counter ping-poll

This command displays the counters for ping polling.

Syntax `show counter ping-poll [<1-100>]`

Parameter	Description
<1-100>	A unique ping poll ID number. This displays the counters for the specified ping poll only. If you do not specify a ping poll, then this command displays counters for all ping polls.

Mode User Exec and Privileged Exec

Output Figure 99-1: Example output from the **show counter ping-poll** command

```
Ping-polling counters
Ping-poll: 1
PingsSent               ......... 15
PingsFailedUpState      ......... 0
PingsFailedDownState    ......... 0
ErrorSendingPing        ......... 2
CurrentUpCount          ......... 13
CurrentFailCount        ......... 0
UpStateEntered          ......... 0
DownStateEntered        ......... 0

Ping-poll: 2
PingsSent               ......... 15
PingsFailedUpState      ......... 0
PingsFailedDownState    ......... 0
ErrorSendingPing        ......... 2
CurrentUpCount          ......... 13
CurrentFailCount        ......... 0
UpStateEntered          ......... 0
DownStateEntered        ......... 0

Ping-poll: 5
PingsSent               ......... 13

UpStateEntered          ......... 0
DownStateEntered        ......... 0
```

Table 99-2: Parameters in output of the **show counter ping-poll** command

Parameter	Description
`Ping-poll`	The ID number of the polling instance.
`PingsSent`	The total number of pings generated by the polling instance.
`PingsFailedUpState`	The number of unanswered pings while the target device is in the Up state. This is a cumulative counter for multiple occurrences of the Up state.
`PingsFailedDownState`	Number of unanswered pings while the target device is in the Down state. This is a cumulative counter for multiple occurrences of the Down state.

Table 99-2: Parameters in output of the **show counter ping-poll** command(cont.)

Parameter	Description
ErrorSendingPing	The number of pings that were not successfully sent to the target device. This error can occur when your device does not have a route to the destination.
CurrentUpCount	The current number of sequential ping replies.
CurrentFailCount	The number of ping requests that have not received a ping reply in the current sample-size window.
UpStateEntered	Number of times the target device has entered the Up state.
DownStateEntered	Number of times the target device has entered the Down state.

Example To display counters for the polling instances, use the command:

```
awplus# show counter ping-poll
```

Related Commands
debug ping-poll
ping-poll
show ping-poll

show ping-poll

This command displays the settings and status of ping polls.

Syntax `show ping-poll [<1-100>|state {up|down}] [brief]`

Parameter	Description	
<1-100>	Displays settings and status for the specified polling instance.	
`state`	Displays polling instances based on whether the device they are polling is currently reachable or unreachable.	
	`up`	Displays polling instance where the device state is reachable.
	`down`	Displays polling instances where the device state is unreachable.
`brief`	Displays a summary of the state of ping polls, and the devices they are polling.	

Mode User Exec and Privileged Exec

Output Figure 99-2: Example output from the **show ping-poll brief** command

```
Ping Poll Configuration
-------------------------------------------------------------
Id Enabled State Destination
-------------------------------------------------------------
1  Yes     Down  192.168.0.1
2  Yes     Up    192.168.0.100
```

Table 99-3: Parameters in output of the show ping-poll brief command

Parameter	Meaning	
Id	The ID number of the polling instance, set when creating the polling instance with the ping-poll command.	
Enabled	Whether the polling instance is enabled or disabled.	
`State`	The current status of the device being polled:	
	`Up`	The device is reachable.
	`Down`	The device is unreachable.
	`Critical Up`	The device is reachable but recently the polling instance has not received some ping replies, so the polled device may be going down.
	`Critical Down`	The device is unreachable but the polling instance received a reply to the last ping packet, so the polled device may be coming back up.

Table 99-3: Parameters in output of the show ping-poll brief command(cont.)

Parameter	Meaning
Destination	The IP address of the polled device, set with the ip (ping-polling) command.

Figure 99-3: Example output from the show ping-poll command

```
Ping Poll Configuration
-------------------------------------------------------

Poll 1:
Description                          : Primary Gateway
Destination IP address               : 192.168.0.1
Status                               : Down
Enabled                              : Yes
Source IP address                    : 192.168.0.10
Critical interval                    : 1
Normal interval                      : 30
Fail count                           : 10
Up count                             : 5
Sample size                          : 50
Length                               : 32
Timeout                              : 1
Debugging                            : Enabled

Poll 2:
Description                          : Secondary Gateway
Destination IP address               : 192.168.0.100
Status                               : Up
Enabled                              : Yes
Source IP address                    : Default
Critical interval                    : 5
Normal interval                      : 60
Fail count                           : 20
Up count                             : 30
Sample size                          : 100
Length                               : 56
Timeout                              : 2
Debugging                            : Enabled
```

Table 99-4: Parameters in output of the show ping-poll command

Parameter	Description
Description	Optional description set for the polling instance with the description (ping-polling) command.
Destination IP address	The IP address of the polled device, set with the ip (ping-polling) command.

Table 99-4: Parameters in output of the show ping-poll command(cont.)

Parameter	Description	
Status	The current status of the device being polled:	
	Up	The device is reachable.
	Down	The device is unreachable.
	Critical Up	The device is reachable but recently the polling instance has not received some ping replies, so the polled device may be going down.
	Critical Down	The device is unreachable but the polling instance received a reply to the last ping packet, so the polled device may be coming back up.
Enabled	Whether the polling instance is enabled or disabled. The active (ping-polling) and no active commands enable and disable a polling instance.	
Source IP address	The source IP address sent in the ping packets. This is set using the source-ip command.	
Critical interval	The time period in seconds between pings when the polling instance has not received a reply to at least one ping, and when the device is unreachable. This is set with the critical-interval command.	
Normal interval	The time period between pings when the device is reachable. This is set with the normal-interval command.	
Fail count	The number of pings that must be unanswered, within the total number of pings specified by the sample-size command, for the polling instance to consider the device unreachable. This is set using the fail-count command.	
Up count	The number of consecutive pings that the polling instance must receive a reply to before classifying the device reachable again. This is set using the up-count command.	
Sample size	The total number of pings that the polling instance inspects when determining whether a device is unreachable. This is set using the sample-size command.	
Length	The number of data bytes to include in the data portion of the ping packet. This is set using the length (ping-poll data) command.	
Timeout	The time in seconds that the polling instance waits for a response to a ping packet. This is set using the timeout (ping polling) command.	
Debugging	Indicates whether ping polling debugging is Enabled or Disabled. This is set using the debug ping-poll command.	

Examples To display the ping poll settings and the status of all the polls, use the command:

```
awplus# show ping-poll
```

To display a summary of the ping poll settings, use the command:

```
awplus# show ping-poll brief
```

To display the settings for ping poll 6, use the command:

```
awplus# show ping-poll 6
```

To display a summary of the state of ping poll 6, use the command:

```
awplus# show ping-poll 6 brief
```

To display the settings of ping polls that have reachable devices, use the command:

```
awplus# show ping-poll state up
```

To display a summary of ping polls that have unreachable devices, use the command:

```
awplus# show ping-poll 6 state down brief
```

Related Commands debug ping-poll
ping-poll

source-ip

This command specifies the source IP address to use in ping packets.

By default, the polling instance uses the address of the interface through which it transmits the ping packets. It uses the device's local interface IP address when it is set. Otherwise, the IP address of the interface through which it transmits the ping packets is used.

The no variant of this command resets the source IP in the packets to the device's local interface IP address.

Syntax

```
source-ip {<ip-address>|<ip-address>}

no source-ip
```

Parameter	Description
<ip-address>	An IPv4 address in dotted decimal notation `A.B.C.D`
<ipv6-address>	An IPv6 address in hexadecimal notation `X:X::X:X`

Mode Ping-Polling Configuration

Examples To configure the ping-polling instance 43 to use the source IP address `192.168.0.1` in ping packets, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 43
awplus(config-ping-poll)# source-ip 192.168.0.1
```

To configure the ping-polling instance 43 to use the source IPv6 address `2001:db8::` in ping packets, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 43
awplus(config-ping-poll)# source-ip 2001:db8::
```

To reset the source IP address to the device's local interface IP address for ping-poll instance 43, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 43
awplus(config-ping-poll)# no source-ip
```

Related Commands

description (ping-polling)
ip (ping-polling)
length (ping-poll data)
ping-poll
show ping-poll

timeout (ping polling)

This command specifies the time in seconds that the polling instance waits for a response to a ping packet. You may find a higher time-out useful in networks where ping packets have a low priority.

The no variant of this command resets the set time out to the default of one second.

Syntax

```
timeout <1-30>
no timeout
```

Parameter	Description
<*1-30*>	Length of time, in seconds, that the polling instance waits for a response from the polled device.

Default The default is 1 second.

Mode Ping-Polling Configuration

Examples To specify the timeout as 5 seconds for ping-poll instance 43, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 43
awplus(config-ping-poll)# timeout 5
```

To reset the timeout to its default of 1 second for ping-poll instance 43, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 43
awplus(config-ping-poll)# no timeout
```

Related Commands

sample-size
show ping-poll
up-count

up-count

This command sets the number of consecutive pings that the polling instance must receive a reply to before classifying the device reachable again.

The no variant of this command resets the up count to the default of 30.

Syntax

```
up-count <1-100>
no up-count
```

Parameter	Description
<1-100>	Number of replied pings before an unreachable device is classified as reachable.

Default The default is 30.

Mode Ping-Polling Configuration

Examples To set the upcount to 5 consecutive pings for ping-polling instance 45, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 45
awplus(config-ping-poll)# up-count 5
```

To reset the upcount to the default value of 30 consecutive pings for ping-polling instance 45, use the commands:

```
awplus# configure terminal
awplus(config)# ping-poll 45
awplus(config-ping-poll)# no up-count
```

The sFlow MIB 100.14

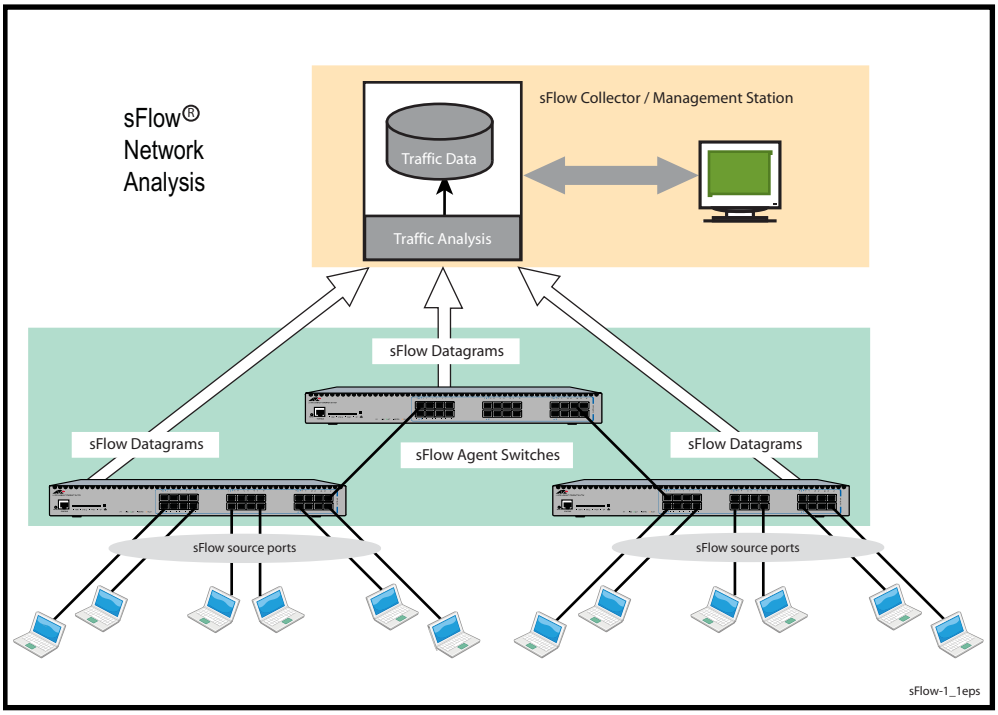
sFlow Introduction

sFlow®[1] provides the ability to monitor traffic in data networks containing switches and routers. A network employing sFlow typically comprises a number of network (sFlow) agents that accumulate sampled data and traffic counter information. The agents then forward this data to a collector. The collector then analyses the information supplied by its agents in order to compile and display statistical profiles of the network and its traffic. The sFlow feature on your switch provides the sFlow Agent capability.

1. sFlow® is a registered trademark belonging to InMon Corp, San Francisco, CA.

Figure 100-1 on page 100.2 shows a basic sFlow network structure. The three network switches also function as sFlow agents. Each agent switch captures samples of the traffic passing through its monitored ports, and sends these samples together with counter information back to the sFlow collector. The agents sample data from a number of switch ports, each acting as an sFlow data source.

Figure 100-1: Basic sFlow Network



The sFlow Agent

Your switch can act as an sFlow agent. The key capabilities of the agent are to:

- sample frames as they pass through selected ports on the switch, and provide sampled extracts of the network traffic.
- periodically capture interface counter data.
- package together the sampled frame and counter information that can be sent to the collector for analysis and display.
- be configurable via SNMP MIB objects.
- communicate to heterogeneous collector devices by means of standard protocols.

Agent components and functionality

sFlow functionality on your switch is based on the requirements defined in of RFC 3176 and its updates defined in the sFlow version 5 memo dated July 2004. This memo can be found at the web site, www.sflow.org/sflow_version_5.txt.

The terms defined in Table 100-1 are used to describe the agent and its functionality on your switch:

Table 100-1: sFlow Terminology

sFlow® Component	Definition
Network Device	Typically either a network switch or router that has the ability to forward frames across an Ethernet network; or between Ethernet networks, in the case of a router.
Data Source (sFlow Source Port)	The location of a sampling point within the switch. This is typically a switch port.
Packet Flow	The path taken by the data (frames) as they traverse a network device.
Sampling Rate	The ratio of frames passing through the data source, to those captured and forwarded as sFlow data. See sflow sampling-rate command on page 101.12.
Counter Sampling	The periodic polling of counters taken at the data source.
sFlow Datagram	A UDP datagram that contains details of sFlow captured data, and counters sent by the sFlow Agent to its Collector.

The sFlow agent (switch) uses sampling technology to derive traffic statistics from its monitored ports. Samples are taken at the sFlow source ports. After collecting its information, the switch then packetizes its samples and statistical data, and sends both to a remote sFlow collector.

Sampling Methods

Two sampling methods are employed within the sFlow agent, frame sampling, and counter sampling. Both sample types are combined within the datagrams sent to the collector. The frame sample data will result in a relatively constant traffic stream, but the counter information is sent where it can fill available space within each datagram. Datagrams are normally sent to the collector at the rate of one each second. However, several datagrams can be sent in rapid succession, where more information exists than can be sent in a single datagram.

Frame Sampling

As frames enter or leave an sFlow source port, they are sampled at a rate determined by the sflow sampling-rate command on page 101.12for that particular port.

Sampling occurs every N frames (on average), where N is the rate value set via sflow sampling-rate command. The sampling rate applies to ingress and egress frames independently. For example, a value of 1000, will sample one frame in every 1000 frames received, one in every 1000 frames sent from the specified port.

Caution

Setting the sFlow sampling rate to a very low value (frequent sampling) can place a heavy load on the switch's CPU. The severity of this loading will increase with the number of ports configured for sampling, the port speeds, and their data sampling rates.

Data Confidentiality

Sampling operates by capturing the initial portion of frames (statistically) selected. The portion sampled is set by the sflow max-header-size command on page 101.9, or SNMP. If the maximum header size is greater than the actual headers in the sampled frames, then portions of the user data (payload) will also be captured and encapsulated in the datagrams sent to the collector. The amount of user data captured can be minimized by careful selection of the maximum header size.

Counter Polling

The function of counter polling is to provide snapshots of various system counters. This produces a series of data counter sets for each port, which can be independently polled at user defined rates, and sent (once a second or less) to the collector. Allied Telesis switches running AlliedWare Plus software support generic interface counters only. For more information on the data types included in the sampling count, see "sFlow Datagrams" on page 100.13.

The sFlow Collector

The sFlow collector receives traffic samples and counter information from a number of sFlow agents. These samples are received as a series of UDP datagrams. From the data contained within these datagrams, the collector is able to provide statistical and or graphical information of network traffic.

The sFlow agent application on your switch supports only a single collector configuration.

sFlow collectors are proprietary third party products. Your switch, running as an sFlow agent has been designed for interoperability with any sFlow collector that supports the sFlow Version 5 specification, including the inMon sFlow collector.

The sFlow Collector may also contain an SNMP Manager that is able to configure sFlow on its agent switches.

Configuring sFlow on your Switch

This section provides some guidelines for setting up the sFlow® agent on your switch. sFlow can be configured directly on your switch - using the CLI, or it can be configured via an SNMP manager. The SNMP management function can be carried out either by a the sFlow collector, or a separate SNMP manager. The configuration examples in this section are shown using the CLI.

Caution

On an x908 with a XEM-2XP module fitted, sFlow sampling does not operate for this XEM when the XEM-2XP is installed in the lowest numbered x908 bay. Ensure that any XEM-2XP modules are not fitted in the lowest bay in an x908.

If a XEM module that is installed in a lower numbered x908 bay is hot swapped then a XEM-2XP module installed in a higher numbered x908 bay may become the XEM in the lowest numbered bay, resulting in sFlow sampling not operating. Ensure that any XEM-2XP modules will not become the XEM in the lowest numbered bay in an x908 by fitting the XEM-2XP in the highest numbered bay.

Caution

The sFlow configurations set either by the switch's CLI, or the sFlow collector. Sometimes the collector will overide the sFlow settings that were initially configured by the CLI, in order to apply "its" own default settings.

If you want to apply the sFlow settings set by the CLI, or by an external network management system, then turn off network management at the collector.

We also advise that as part of your sFlow commissioning process, you review your security access procedures relating to sFlow access and its data traffic management.

sFlow configuration can vary greatly with your overall configuration, data profile, and monitoring intensity. Also, many interdependencies existing between parameter settings. For this reason, few firm configuration settings are recommended in this software reference, but instead these parameter relationships are explained and some typical configuration examples are shown.

The default settings on your switch have sFlow turned off for all ports.
The following commands are used to setup and configure sFlow on your switch. These are introduced in the order in which you would logically need to use them.

sFlow Command	Functionality
sflow enable	enables sFlow on your switch (or stack).
sflow max-header-size	sets the maximum sFlow data capture size.
sflow collector max-datagram-size	sets the maximum size for the agent to collector datagrams.
sflow agent (address)	sets the sFlow agent IP address on the switch.
sflow polling-interval	sets the counter polling interval for specified ports.
sflow sampling-rate	sets the mean sampling rate for specified ports.
sflow collector (address)	the sFlow agent's collector IP address and/or UDP port.

Configuration Procedure

The following process sets out a systematic procedure to configure sFlow on your switch:

Information Gathering

sFlow configuration is dependant on your network structure and its data. Start by gathering together the following information.

- Obtain (or determine) the sFlow collector IP address.
- Select an appropriate UDP port for your sFlow datagrams. The recommended value is 6343, and is the default value preconfigured on your switch.
- Select an appropriate IP address for your sFlow agent. We recommend that you use the local IP address of your switch. For more information on local addresses and how to set them up, see the interface (to configure) command on page 11.3.
- Assess the sensitivity of the data that your sFlow agent will be sampling.
- Obtain details of the protocols that your sFlow agent will be sampling. If you intend sampling unusual or proprietary protocols, obtain details of their header lengths.
- Calculate the most appropriate max-header-size for your sFlow sampling.
- Select the ports that you want to sample, and their sample rate.
  These two factors vary (not quite) proportionally; so if you double the number of ports and double your sampling rate (i.e. sample half as many frames) then you will “almost” return to your earlier situation. Also note the speeds of the ports you have selected, because - for the same port utilization - the faster the port speed, the greater the load on the CPU.
- Review the speed of the port used to transport the sFlow datagrams to the collector. Unless configured to a specific port, the collector traffic will share the same network port with other traffic.

  The capacity of the collector port should be sufficient to carry the volume of sFlow traffic. This topic is expanded on in the Configuration Examples later in this chapter.

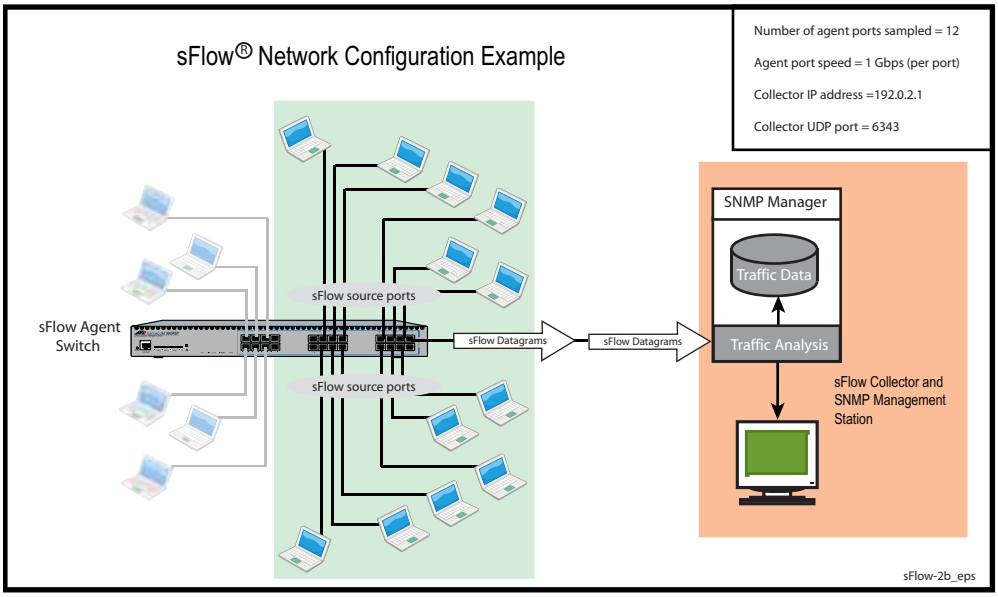
Managing the sFlow processing overhead

The sFlow data sampled on the ports converges into the CPU for processing and UDP packetizing. Therefore one of the major factors when configuring sFlow is to prevent the sFlow data volumes from placing a significant overhead on the CPU processing. The two most significant factors here are, the number of ports sampled, and the sampling rate. The other (and lessor) factors in this equation are the frame size distribution and the maximum header size. The shorter the frames are on the network, the heavier the sFlow processing load will be (for the same number of frames per second). Conversely the shorter the maximum header size selected, the lighter the sFlow processing load will be (because less data per frame is sent to the CPU).

Configuration Examples

This section provides a configuration example based on the network shown below:

Figure 100-2: sFlow Configuration Example



Step 1: Determine the IP addresses and UDP ports.

Collector IP address is 192.0.2.65

sFlow UDP port uses the default of 6343

Agent (local) IP address 192.0.2.33. This is the address that the collector may use to configure the agent via SNMP.

Step 2: Determine the maximum sFlow Datagram size.

Datagrams will be sent at one second intervals regardless of the amount of data they contain. If the amount of data to be sent is greater than the maximum datagram size, then several datagrams will be sent in quick succession - within the 1 second interval. The objective is to contain the sFlow information in a the minimum number of datagrams. That is. to fragment datagrams when necessary, but do it as little as possible.

Find the maximum datagram size that will pass through all network components without fragmenting. Then set the sFlow datagram size a little less than this value.

The maximum datagram size should be less than the MTU size.

For this example, the MTU is assumed to be set to its default of 1500 bytes. In this situation we could leave the maximum Datagram size at its default of 1400 bytes; but in order to show this as a configuration step, we will change it to 1200 bytes.

Note

sFlow datagrams are generally transmitted at 1 second intervals. However, where there is more information than can fit into one datagram, several datagrams are sent sequentially, within the 1 second time frame.

Step 3: Determine the max-header-size for the sampled data.

The maximum header size for the sampled data is set by the sflow max-header-size command. The optimum setting is to capture only the header portion of the frame and discard the user-data portion. This is especially important where the user data contains sensitive information.

Keeping the max-header-size as small as possible has the additional benefit of lightening the CPU load.

First, inspect the nature of the data to be sampled and the protocols used to carry it.

For this example we will assume that the network contains Ethernet II frames with the 4 byte 802.1Q header component, IP, TCP protocols. In this situation the following rules can be applied:

For an environment using standard TCP\IPv4 over Ethernet frames, consider the following protocol basics.

Ethernet header (including the 4 byte 802.1Q header component) = 18 bytes

IPv4 header = 24 bytes

TCP header = 24 bytes

Total = 66 bytes

A similar calculation can be made for an environment using IPv6 over Ethernet.

Ethernet header (including the 4 byte 802.1Q component) = 18 bytes

IPv6 header = 40 bytes

TCP header = 24 bytes

Total = 82 bytes

Caution In the above network scenarios:

- For IPv4 - any data existing between 66 bytes and the value set by this command will be included in the sFlow packet samples. For example, with the default of 128 applied, up to 128-66=62 bytes of user data could be included in the sFlow datagram samples sent between the Agent and the Collector.
- For IPv6 - any data existing between 82 bytes and the value set by this command will be included in the sFlow packet samples. For example, with the default of 128 applied, up to 128-82=46 bytes of user data could be included in the sFlow datagram samples sent between the Agent and the Collector.

For this example the sflow max-header-size will be set to 68 bytes (assuming an Ethernet - IPv4 - TCP environment).

Step 4: Select ports to sample

Each sampled sFlow port speed is 1 Gbps

12 ports have been selected for sampling

Check that none of the ports selected have mirroring configured. sFlow will not operate if any port on the switch is configured for mirroring.

Note When sampling is across ports that form an aggregated link, statistics will be extracted on traffic across all links, but their display is shown as if all traffic is flowing through the first physical link created.

Step 5: Determine the sampling rate

Selecting the sampling rate involves a trade-off between sFlow requirements, and system loading. The greater the sampling rate, the more samples will be taken, and the more accurate their results will be. Unfortunately, taking more samples increases the load on the switch CPU and on the network connection to the collector.

For this particular configuration, the value of the sampling rate was set to 512 so as to present a light load on the CPU.

Step 6: Review and adjust settings

Because sFlow traffic loading will vary with the traffic profile, the following general assumptions are made. The following traffic profile is assumed.

- 50 % of frames are <200 bytes long
- 40 % of frames are >1400 bytes long

The following settings are:

- 12 x 1 Gbps ports are being sampled
- sFlow max-header size = 68 bytes
- sampling rate (N = 512)
- average port utilization is assumed to be approximately 60 %
- average data rate to the collector is assumed to be approximately 1.5 Mbps

When setting the sampling rate, consider the following factors that will affect the CPU load. This load will increase (not necessarily linearly) as you:

- increase the number of ports configured
- increase the port speeds
- decrease the sampling rate
- increase the max-header-size

For this configuration the average sFlow collector traffic is expected to be approximately 1.5 Mbps. In this example the agent-to-collector traffic will be shared with non-sFlow traffic. Although not described in this example, you can specifically configure the collector port to route only sFlow traffic. To do this you would need to assign a separate VLAN (and IP address) to the agent-to collector interface and direct your sFlow traffic to this interface.

We advise that you ensure adequate bandwidth is provided for both the sFlow and general traffic that could share its network connection.

We will now use these settings to configure the network.

Configuration Procedure

The following steps apply the settings obtained in the previous section.

Step 1: Configure sFlow

Enable sFlow on the switch

`awplus#`	
`configure terminal`	Enter Global Configuration Mode.
`awplus(config)#`	
`sflow enable`	Enable the sFlow agent globally on the switch.

Step 2: Configure the sFlow Collector Settings

Set the sFlow collector max-datagram size

`awplus(config)#`	
`sflow collector max-datagram-size 1200`	Set the maximum size of the sFlow datagrams to 1200 bytes.

Set the sFlow collector (address)

`awplus(config)#`	
`sflow collector ip 192.0.2.65`	Set the sFlow collector address to 192.0.2.65.

Step 3: Configure the sFlow Agent Settings

Set the sFlow agent (address)

`awplus(config)#`	
`sflow agent ip 192.0.2.33`	Set the sFlow agent address to 192.0.2.33.

Set the sFlow sampling rate on sFlow Source Ports

`awplus(config)#`	
`interface port1.0.11-port1.0.22`	Select the port range to configure (ports 1.0.11 to 1.0.22).
`awplus(config-if)#`	
`sflow sampling-rate 512`	Set the sampling rate on the selected ports.

Step 4: Check the Configuration

View the sFlow Configuration	
awplus(config-if)#	
do sh running-config sflow	Validate that sFlow is enabled Note that the prefix “do” enables you to run an Exec Mode command from an Interface Mode prompt.

Figure 100-3: Output from the **show running-config sFlow** command

```
awplus#sh run sflow
!
sflow agent ip 192.0.2.33
sflow collector ip 192.0.2.65
sflow collector max-datagram-size 1200
sflow enable
!
interface port1.0.11-port1.0.22
 sflow sampling-rate 512
```

sFlow Datagrams

After data sampling and counter information has been gathered, each sFlow agent packetizes the data and sends it to an sFlow collector where it can be analyzed and displayed in charts and tables etc.

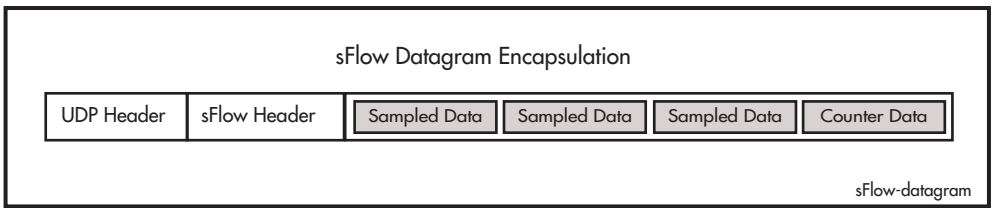
This packetized data is sent to the collector in UDP datagrams. These datagrams bear the IP address of the collector and the port number 6343. Using a standardized port helps to avoid configuration problems between the sFlow agents and collectors.

Although an analysis of the sFlow datagrams is outside the scope of this document, some basic information is provided here for those interested in knowing the basic components of the sFlow datagrams. The full specification of the sFlow protocol can be found at www.sflow.org/sflow_version_5.txt.

sFlow datagrams comprise three basic components:

- Datagram header information
- Flow sample information - may contain several samples
- Counter statistical information - fitted in where space permits

Figure 100-4: sFlow Datagram Encapsulation



The content of these datagram components is listed below:

sFlow Header Fields

- Version (The sFlow version being used)
- IP Address Type (Can be either an IPv4 or IPv6 address type)
- Source IP Address (The IP address of the sFlow agent)
- Sequence Number (The datagram sequence number)
- System Up-time
- Sample Count (The number of samples in the datagram)
- Sample Dataset

sFlow Flow Sample Fields

- Flow Sample 1 (The first sample)
- Sample Type (Flow Sample, 0x0001)
- Sample Sequence Number (of flow samples)
- Sampler ID
- Sampling Rate (as set by the "sflow sampling-rate" on page 101.12 or SNMP)
- Sample Pool (the total number of packets that could have been sampled)
- Packets Dropped (the number of packets dropped, due to a lack of resources)
- Input (the interface that the packet was received on - not supported)
- Output (the index number of the interface that the packet was sent from) (Note that your collector should have the ability via SNMP to resolve index numbers to physical port numbers)
- Packet Type
- Header Protocol - Ethernet ISO 88023(1)
- Packet Size (Frame Length including the FCS)
- Header Length - The sampled portion of the frame as set by the "sflow max-header-size" on page 101.9. May be shorter for small frames.
- Header Bytes

- Extended Elements Number
- Extended Elements

Note that in practice the Ethernet header is usually followed by components for the IP, TCP, and user data.

sFlow Flow Sample Fields

- Counter Sample
- Sample Type (Counter Sample, 0x0002)
- 'Sample Sequence Number
- Sample ID (source ID index value)
- Sample Interval (as set by the "sflow polling-interval" on page 101.11)
- Counter Type (1=generic, 2=Ethernet)

Generic Interface Counters

- ifIndex
- ifType
- ifSpeed
- ifDirection (0=unknown, 1=full-duplex, 2=half-duplex, 3=in, 4=out
- ifStatus
- InOctets
- InUcastpackets
- InMulticast packets
- InBroadcast packets
- InDiscarded packets (= 0)
- InPackets containing errors
- InPackets containing unknown protocols (= 0)
- OutOctets
- OutUcast packets
- OutMulticast packets
- OutBroadcast packets
- OutDiscarded packets
- OutPackets containing errors
- ifPromiscuous Mode

Ethernet Interface Counters

- dot3Stats Alignment Errors (= 0)
- dot3Stats FCS Errors
- dot3Stats Single Collision Frames (= 0)
- dot3Stats Multiple Collision Frames
- dot3Stats SQE Test Errors
- dot3Stats Deferred Transmissions (= 0)
- dot3Stats Late Collisions
- dot3Stats Excessive Collisions
- dot3Stats Internal Mac Transmit Errors
- dot3Stats Carrier Sense Errors (= 0)
- dot3Stats Frame Too Longs
- dot3Stats Internal Mac Receive Errors
- dot3Stats Symbol Errors (= 0)

The sFlow MIB

Your switch fully supports inMon's sFlow MIB. For more information, see "Private MIBs" on page 89.70, and the website www.sflow.org/SFLOW-MIB5.txt.

Chapter 101: sFlow Commands

show sflow interface 101.16
undebug sflow 101.16

Command List

This chapter provides an alphabetical reference for sFlow commands.

debug sflow

This command enables sFlow® debug message logging, for sFlow sampling and polling activity on the specified ports. If no ports are specified, sampling and/or polling debug messages are enabled for all ports.

The no variant of this command disables sFlow sampling and or polling debug message logging on the ports selected. If no ports are specified, sampling and/or polling debug messages are disabled on all ports.

Syntax

```
debug sflow [interface <port-list>] [sampling][polling]
no debug sflow [interface <port-list>] [sampling][polling]
```

Parameter	Description
`interface`	Interface information.
`<port-list>`	The ports for which sFlow debug is to be enabled. The ports to display information about. The port list can be: ■ a switch port (e.g. `port1.2.12`) ■ a continuous range of ports separated by a hyphen, e.g. `port1.0.1-1.0.24` ■ a comma-separated list of ports and port ranges, e.g. `port1.0.1,port1.1.1-1.2.24`.
`sampling`	Debug sFlow sampling for the specified port(s).
`polling`	Debug sFlow polling for the specified port(s).

Default The sFlow sampling and or polling debug is disabled.

Mode Privileged Exec

Examples To enable sFlow debug message logging for polling and sampling on `port1.0.1` and `port1.0.7`, use the commands:

```
awplus# debug sflow interface port1.0.1,port1.0.7 sampling
       polling
```

To enable logging and polling of sFlow debug messages for polling and sampling on all ports, use the command:

```
awplus# debug sflow sampling polling
```

Related Commands show debugging sflow
no debug all

debug sflow agent

This command enables sFlow® debug message logging that is not specific to particular ports. For example, sending an sFlow datagram to the collector.

The no variant of this command applies the command default.

Syntax

```
debug sflow agent
no debug sflow agent
```

Default The sFlow agent debug message logging (that is not port specific) is disabled.

Mode Privileged Exec

Example To enable logging of sFlow agent debug messages, use the following command:

```
awplus# debug sflow agent
```

Related Commands show debugging sflow
debug sflow

sflow agent (address)

This command sets the sFlow® agent IP address on the switch. This address is inserted into every sFlow datagram sent from the sFlow agent switch to the sFlow collector device. The sFlow collector can then uses this address to uniquely identify and to access the switch, such as for SNMP. We therefore recommend that you change this address as little as possible.

Although the agent address can be set to any valid IPv4 or IPv6 address; we recommended that you set the sFlow® agent IP address to be the local address[1] that is configured on the switch. This ensures that the sFlow collector can maintain connectivity to the switch irrespective of the addition or deletion of VLAN interfaces (each of which will have its own specific IP address). Note that sFlow is rendered inactive whenever the agent address is not set.

1. For information on local addresses and how to set them up, see the interface (to configure) command on page 11.3.

The no variant of this command applies its default setting to remove a configured address.

Syntax

```
sflow agent {ip <ip-address>|ipv6 <ipv6-address>}
no sflow agent {ip|ipv6}
```

Parameter	Description
<ip-address>	The IPv4 address of the switch that is acting as the sFlow agent.
<ipv6-address>	The IPv6 address of the switch that is acting as the sFlow agent. The IPv6 address uses the format X:X::X:X.

Default The sFlow agent address is unset.

Mode Global Configuration

Examples To set the sFlow agent (IPv4) address to `192.0.2.23`, use the command:

```
awplus# configure terminal
awplus(config)# sflow agent ip 192.0.2.23
```

To remove the sFlow agent (IPv4) address, use the command:

```
awplus# configure terminal
awplus(config)# no sflow agent ip
```

To set the sFlow agent (IPv6) address to `2001:0db8::1`, use the command:

```
awplus# configure terminal
awplus(config)# sflow agent ipv6 2001:0db8::1
```

To remove the sFlow agent (IPv6) address, use the command:

```
awplus# configure terminal
awplus(config)# no sflow agent ipv6
```

Related Commands show running-config sflow
show sflow

sflow collector (address)

This command sets the sFlow® agent's collector IP address and/or UDP port. This is the destination IP address and UDP port, for sFlow datagrams sent from the sFlow agent. The IP address can be any valid IPv4 or IPv6 address. Note that sFlow is rendered inactive whenever the collector address is set to 0.0.0.0 (for IPv4) or `::` (for IPv6).

The no variant of this command returns the IP address and UDP port values to their defaults, which will result in sFlow being deactivated.

Syntax

```
sflow collector {[ip <ip-address>|ipv6 <ipv6-address>]|
   [port <1-65535>]}

no sflow collector {[ip|ipv6]|[port]}
```

Parameter	Description
<ip-address>	IPv4 address of the remote sFlow collector.
<ipv6-address>	IPv6 address of remote sFlow collector. The IPv6 address uses the format X:X::X:X.
`port`	Destination UDP port for sFlow datagrams sent to the collector.
<1-65535>	UDP port number (default: 6343).

Default The collector address is `0.0.0.0` (which renders sFlow inactive), and the UDP port is `6343`.

Mode Global Configuration

Examples To set the sFlow collector address to `1920.2.25` and UDP port to `9000`, use the command:

```
awplus# configure terminal
awplus(config)# sflow collector ip 192.0.2.25 port 9000
```

To remove the sFlow collector IPv4 address and leave the UDP port unchanged, use the command:

```
awplus# configure terminal
awplus(config)# no sflow collector ip
```

To remove the sFlow collector IPv4 address and to remove the UDP port, use the command:

```
awplus# configure terminal
awplus(config)# no sflow collector ip port
```

To set the sFlow collector address to `2001:0db8::1` and leave the UDP port unchanged, use the command:

```
awplus# configure terminal
awplus(config)# sflow collector ipv6 2001:0db8::1
```

To remove the sFlow collector IPv6 address and leave the UDP port unchanged, use the command:

```
awplus# configure terminal
awplus(config)# no sflow collector ipv6
```

To remove the sFlow collector IPv6 address and to remove the UDP port, use the command:

```
awplus# configure terminal
awplus(config)# no sflow collector ipv6 port
```

Related Commands show running-config sflow
show sflow

sflow collector max-datagram-size

This command sets the maximum size of the sFlow® datagrams sent to the collector.

The no variant of this command resets the maximum-datagram-size to the default.

Syntax

```
sflow collector max-datagram-size <200-1500>
no sflow collector max-datagram-size
```

Parameter	Description
<200-1500>	The maximum number of bytes that can be sent in an sFlow datagram sent from the agent to the collector.

Default 1400 bytes

Mode Global Configuration

Example To set the maximum datagram size to 1200, use the command:

```
awplus# configure terminal
awplus(config)# sflow collector max-datagram-size 1200
```

Related Commands show running-config sflow
show sflow

sflow enable

This command enables sFlow® globally on the switch. Note that sFlow cannot be enabled if Tx port mirroring is enabled on any port on the device.

The no variant of this command disables sFlow globally on the switch.

Note that enabling sFlow does not automatically set its operational status to active. To activate sFlow the following conditions need to be met:

- sFlow is enabled.
- The sFlow agent address is set.
- The sFlow collector address is set to a valid (non zero) IPv4 or IPv6 address.
- Polling or sampling is enabled on the ports to be sampled or polled.

Syntax

```
sflow enable
no sflow enable
```

Default sFlow is disabled globally on the switch.

Mode Global Configuration

Example To enable sFlow operation, use the command:

```
awplus# configure terminal
awplus(config)# sflow enable
```

Related Commands

show running-config sflow
show sflow

sflow max-header-size

This command sets the maximum header size of the ethernet frames sampled on a specified port. The maximum header size is measured in bytes, referenced from the first byte of the ethernet destination address and excludes the ethernet FCS fields.

If a sampled ethernet frame is longer than the maximum header size set by this command, then the frame will be truncated to the first N bytes before being placed in the sFlow datagram, where N is the maximum header size set by this command.

The no variant of this command resets the max-header-size to its default.

Syntax

```
sflow max-header-size <14-200>

no sflow max-header-size
```

Parameter	Description
<14-200>	The maximum number of header bytes to be sampled.

Default The max-header-size is 128 bytes.

Mode Interface Configuration

Usage The header size is measured from the first byte of the Ethernet frame MAC Destination Address.

For an environment using standard TCP IPv4 over Ethernet frames, consider the following basic protocol structure:

Ethernet header (including the 4 byte 802.1Q header component) = 18 bytes

IPv4 header = 24 bytes

TCP header = 24 bytes

Total = 66 bytes

See “Determine the max-header-size for the sampled data.” on page 100.9 for more information on configuring this command

A similar consideration can be made for an environment using TCP IPv6 over Ethernet:

Ethernet header (including the 4 byte 802.1Q header component) = 18 bytes

IPv6 header = 40 bytes

TCP header = 24 bytes

Total = 82 bytes

Caution

In the above network scenarios:

- For IPv4 - any data existing between 66 bytes and the value set by this command will be included in the sFlow packet samples. For example, with the default of 128 applied, up to 128-66=62 bytes of user data could be included in the sFlow datagram samples sent between the Agent and the Collector.
- For IPv6 - any data existing between 82 bytes and the value set by this command will be included in the sFlow packet samples. For example, with the default of 128 applied, up to 128-82=46 bytes of user data could be included in the sFlow datagram samples sent between the Agent and the Collector.

Note that the agent-to-collector datagrams contain their own UDP headers, which are outside this calculation.

Example To set the maximum header size to 160 bytes for ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# sflow max-header-size 160
```

Related Commands

show running-config sflow
show sflow interface
sflow max-header-size

sflow polling-interval

This command sets the sFlow® counter polling interval (in seconds) for the specified ports. A value of 0 disables polling. A counter sample is taken every N seconds where N is the value set by this command.

The no variant of this command applies the default.

Syntax

```
sflow polling-interval {0|<1-16777215>}
no sflow polling-interval
```

Parameter	Description
0	Disable polling (the default).
<1-16777215>	The polling interval in seconds.

Default The polling-interval is 0 (polling disabled).

Mode Interface Configuration

Example To set the polling interval to 60 seconds for ports 1.0.1 and 1.0.7, use the following commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# sflow polling-interval 60
```

Related Commands

show running-config sflow
show sflow interface

sflow sampling-rate

This command sets the mean sFlow® sampling rate for the specified ports. Sampling occurs every N frames (on average), where N is the rate value set via this command. The sampling rate applies to ingress and egress frames independently. For example, a value of 1000 will sample one frame in every 1000 frames received. One in every 1000 frames sent from the specified port. A value of 0 disables sampling on the specified ports.

The no variant of this command applies the default.

Syntax

```
sflow sampling-rate {0|<50-2147483647>}
no sflow sampling-rate
```

Parameter	Description
0	Sets the default.
<50-2147483647>	The sampling rate N, measured in ethernet frames.

Default The sampling-rate is 0 (sampling disabled).

Mode Interface Configuration

Example To set the sampling rate to 500 for ports 1.0.1 and 1.0.7, use the commands:

```
awplus# configure terminal
awplus(config)# interface port1.0.1,port1.0.7
awplus(config-if)# sflow sampling-rate 500
```

Related Commands

show running-config sflow
show sflow interface

show debugging sflow

This command displays sFlow® debug settings for agent operation, and for sampling and polling on specific interface ports. If no interface ports are specified, sampling and polling will be applied to all ports.

Syntax

```
show debugging sflow [interface <port-list>]
```

Parameter	Description
`interface`	The interface information.
`<port-list>`	The ports for which the sFlow debug settings are to be shown. The ports to display information about. The port list can be: ■ a switch port (e.g. `port1.2.12`) ■ a continuous range of ports separated by a hyphen, e.g. `port1.0.1-1.0.24` ■ a comma-separated list of ports and port ranges, e.g. `port1.0.1,port1.1.1-1.2.24`.

Mode User Exec and Privileged Exec

Example To display sFlow debug settings on the agent, and for sampling and polling on ports 1.0.1 to 1.0.9, use the command:

```
awplus# show debugging sflow interface port1.0.1-1.0.9
```

Output

Figure 101-1: Sample obtained for an sFlow agent

```
awplus# show debugging sflow interface port1.0.1-1.0.9

sFlow Agent Debug:    Enabled

          Sampling      Polling
Port       Debug         Debug
-------------------------------
1.0.1     Enabled       Enabled
1.0.2     Enabled          -
1.0.3        -             -
1.0.4        -             -
1.0.5        -             -
1.0.6        -          Enabled
1.0.7        -             -
1.0.8        -          Enabled
1.0.9        -          Enabled
```

To display sFlow debug settings for all ports, use the command:

```
awplus# show debugging sflow
```

Related Commands

show running-config sflow
show sflow interface

show running-config sflow

This command displays the running system information specific to the sFlow feature.

Syntax `show running-config sflow`

Mode Privileged Exec and Global Configuration

Example To display the sFlow running configuration information, use the command:

```
awplus# show running-config sflow
```

Output Figure 101-2: Example output from the **show running-config sflow** command

```
awplus#sh run sflow
!
sflow agent ip 192.0.2.33
sflow collector ip 192.0.2.65
sflow collector max-datagram-size 1200
sflow enable
!
interface port1.0.11-port1.0.22
 sflow sampling-rate 512
```

Related Commands show running-config

show sflow

This command displays non-port-specific sFlow agent configuration and operational status.

Syntax `show sflow`

Mode Privileged Exec

Example To display sFlow configuration and operational status, use the command:

```
awplus#  show sflow
```

Output

Figure 101-3: Example output from the **show sflow** command

```
sFlow Agent Configuration:                    Default Values
  sFlow Admin Status ........ Disabled        [Disabled]
  sFlow Agent Address ....... [not set]       [not set]
  Collector Address ......... 0.0.0.0         [0.0.0.0]
  Collector UDP Port ........ 6343            [6343]
  Tx Max Datagram Size ...... 1200            [1400]

sFlow Agent Status:
  Polling/sampling/Tx ....... Inactive because:
                                - sFlow is disabled
                                - Agent Addr is not set
                                - Collector Addr is 0.0.0.0
                                - Polling & sampling disabled
                                  on all ports
```

Table 101-1: Parameters in the output of the **show sflow** command

Output Parameter	Description
`sFlow Admin Status`	Whether sFlow agent operation is administratively enabled.
`sFlow Agent Address`	The sFlow agent IPv4 or IPv6 address for the device. sFlow is rendered inactive whenever the agent address is not set.
`Collector Address`	The IPv4 or IPv6 collector address to which sFlow datagrams are sent. sFlow is rendered inactive whenever the collector address is set to 0.0.0.0 or 0:0::0.0.
`Collector UDP Port`	The UDP port on the collector to which sFlow datagrams are sent.
`Tx Max Datagram Size`	The maximum size of the sFlow datagrams sent to the collector.
`Polling/sampling/Tx`	Whether sFlow sampling and/or polling (and hence sFlow datagram transmission) are active. If inactive the reasons are listed.

Related Commands show running-config sflow
show sflow interface

show sflow interface

This command displays sFlow agent sampling and polling configuration for specified ports.

Syntax `show sflow interface <ifrange>`

Parameter	Description
<ifrange>	The interface range.

Mode Privileged Exec

undebug sflow

This command applies the functionality of the no debug sflow command.

VCStack Introduction

This chapter describes Virtual Chassis Stacking (VCStack), its features, and basic connection examples. For detailed descriptions of the commands used to configure VCStack, see Chapter 103, Stacking Commands.

A Virtual Chassis Stack (VCStack) is a group of physically separate switches that are connected so as to function as a single logical switch. In order to function as a VCStack, its component switches are connected using high-speed stacking links.

Features of Virtual Chassis Stacking

Creating a VCStack greatly eases network management, because you can configure all the stacked devices via a single IP address. Creating a VCStack will often eliminate your need to configure protocols such as VRRP and Spanning Tree. VCStack also enables you to create highly resilient networks. This resiliency can be applied in several ways.

Within the stack itself, switch interconnection is via two links. The second link is able to provide an alternative data path, thus the stack will continue to function if a single switch fails. Degraded performance might occur however, due to the reduced VCStack bandwidth.

User ports can also be made extremely resilient by utilizing link aggregation. Aggregated links can span ports, modules, and even switches within the stack. Creating aggregated links that span multiple switches within a stack creates an extremely resilient configuration. Communication will still exist even if a switch and its aggregated ports fail. Refer to Figure 102-4 on page 102.6.

VCStack Supported Platforms

VCStack is supported on the following switch types:

- x900-24XT, x900-24XS, x900-24XT-N
- x900-12XT/s
- SwitchBlade® x908

VCStack supports a maximum of two devices per stack on the x900 and SwitchBlade x908 series switches. Switches must be of the same product type to exist within the same stack. The principles of product / stack compatibility are shown in the following table.

Table 102-1: Stacking compatibility by product type

Product Types	x900-24XS, x900-24XT, x900-24XT-N	Via XEM-STK ports.
Product Type	x900-12XT/s	Via XEM-STK ports.
Product Type	SwitchBlade® x908	Via either XEM-STK ports, or high speed rear chassis ports.

The Physical Stack

A stack comprises two individual stack members interconnected via a high-speed stacking link. A stack always has a primary stack member called the stack master, and a secondary stack member called the backup member.

The basic stack configurations are:

- Two stack members connected in a ring topology via their stack XEM modules. All models.
- On SwitchBlade® x908 two stack members can connected via their back-plane chassis connections—a variation of the ring topology.

XEM module - cables and connections

The XEMStack ports use special cables to construct the physical stack; these are:

- AT-XEM-STK-CBL0.5 (0.5 metres long)
- AT-XEM-STK-CBL2.0 (2 metres long)

Chassis rear - cables and connections

The chassis rear stacking ports use special cables to construct the physical stack; these are:

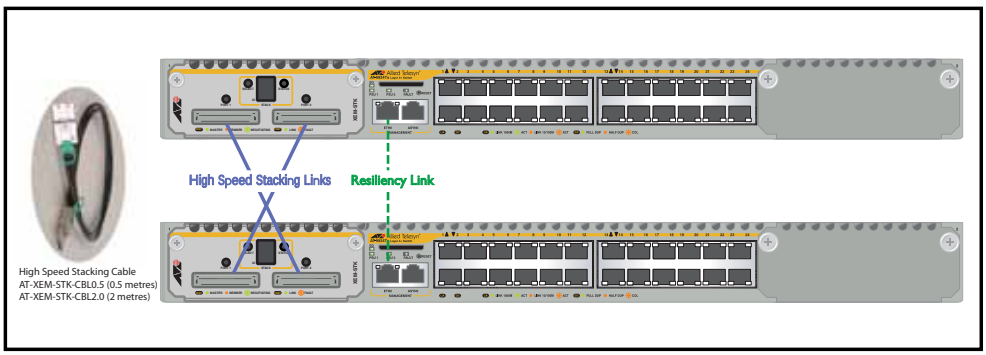
For the back panel chassis connections on the SwitchBlade x908, use the cable type AT-HS-STK-CBL1.0 (1 metre long).

Note Port 1 on one switch must connect to port 2 on the other (or next) switch.

Two Switch Stack Configuration

This configuration, shown in Figure 102-1 on page 102.3, uses two switches that are connected via their high-speed stacking links and an optional resiliency link. Note that stacking ports labeled 1 must connect to stacking ports labeled 2. In this configuration the stack can still function using only a single high speed link.

Figure 102-1: Two Switch Stack Configuration



On the SwitchBlade® x908, the two switch configuration can use either the connections on a XEM stacking module, or use stacking ports 1 and 2 located on the chassis rear panel. The chassis rear panel connections have a faster data rate, but do require a special cable.

Resiliency link

The resiliency link carries no network data. Its function is to provide additional stack status information to enable the stack members to more accurately decide whether it is appropriate for one of them to take over the role of stack master if the existing master fails. See "Stack Resiliency Link" on page 102.14.

A resiliency link can be created using a single physical connection between two eth0 ports, or it can use a VLAN (resiliency link VLAN) to which the switch ports can be attached.

To create a resiliency link using eth0 ports, connect a standard twisted pair LAN cable (either straight through, or crossover—MDI-MDIX negotiation is supported on these ports) between the two eth0 ports on both devices. Once you have connected the cable you can run the stack resiliencylink command on page 103.34 to create the resiliency link.

Resiliency link configurations via switch ports

Two resiliency-link configurations that use switch ports are shown below. Figure 102-2 shows the resiliency link connecting in a ring topology, whilst Figure 102-3 shows the resiliency link connecting to the switch ports via a network hub. In both configurations, the resiliency link connections are made using a designated VLAN running over switch-port connections between each stack member. For more information on using the resiliency link commands see: stack resiliencylink command on page 103.34 and switchport resiliencylink command on page 103.40.

Figure 102-2: Resiliency link connecting to switch ports over the ResiliencyLink VLAN

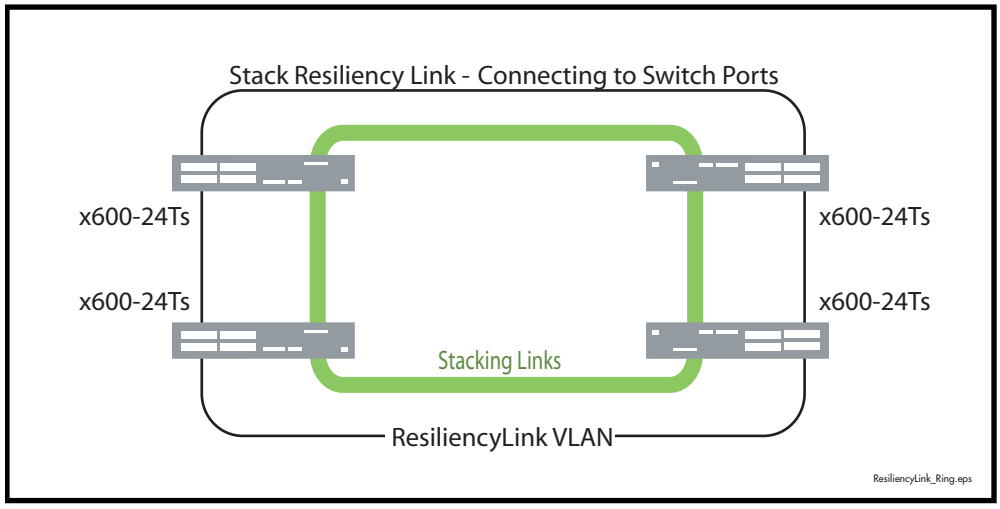


Figure 102-3: Resiliency link connecting to switch ports over the ResiliencyLink VLAN using a network hub.

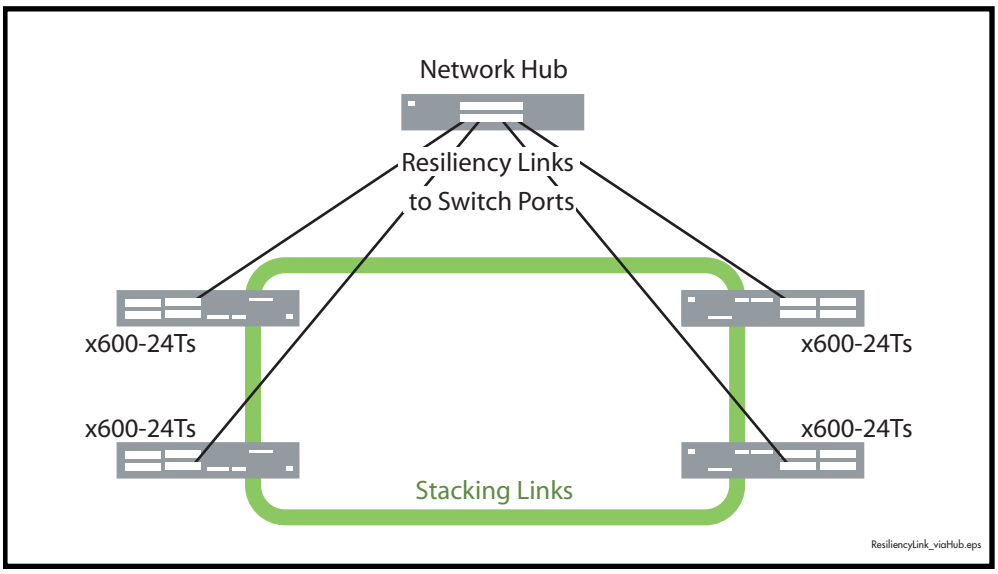
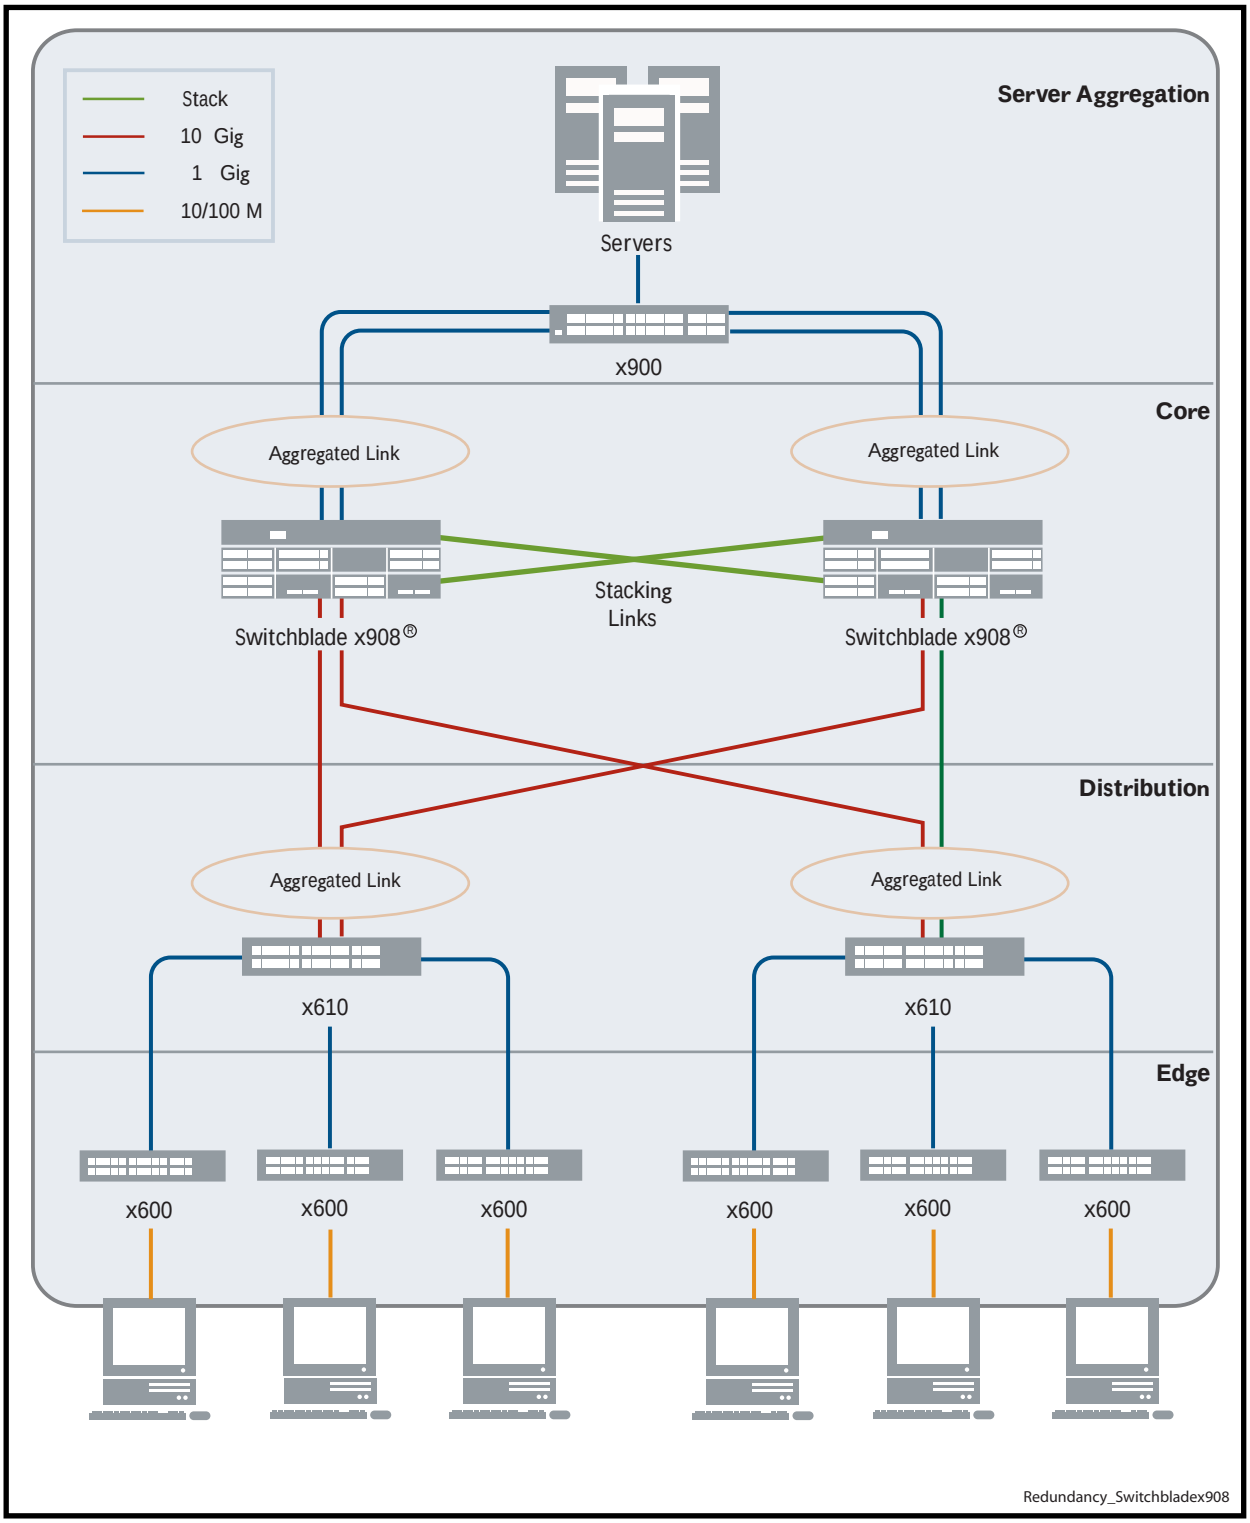


Resilient Stacked Topology

Where network connectivity uptime is a major criteria, you can use virtual chassis stacking to create highly reliable network configurations. The network shown in Figure 102-4 employs duplicate links and switches to create a stacked network that offers extremely reliable user connectivity.

Figure 102-4: VCStack Resilient Stacked Topology Example



This network employs two SwitchBlade® x908 switches to form an expandable network core. These switches are stacked and so appear as a single logical switch (note that smaller switches such as the x610 can be also be used to form the stacked core).

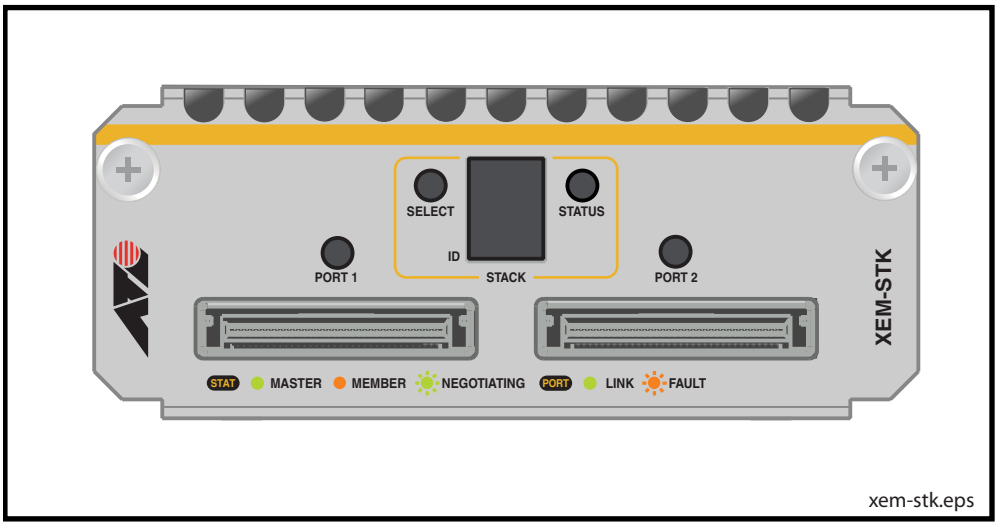
This network topology supplies multiple dual connections to a number of downstream distribution switches that can in turn connect to user devices. Similarly, the dual network paths provide very reliable connectivity to the server aggregation portion of the network.

Employing link aggregation rather than spanning tree to manage the parallel paths, enables the bandwidth of both data links to be utilized under normal conditions, whilst enabling a single data link to operate should its partner link fail.

Stack Formation

As previously mentioned, a VCStack always contains a stack master and a stack member. To be part of a stack, a switch must connect to the other potential stack member via dedicated stacking ports. These ports can either be those on the front of a XEM-STK stacking module, or in the case of the SwitchBlade x908, the stacking ports located on the back panel. Figure 102-5 on page 102.8 shows a stacking XEM-STK module.

Figure 102-5: VCStack Stacking Module (XEM-STK)



On the SwitchBlade® x908, at least one non XEM-STK must be installed in the switch before it is able to participate as a stack member. The SwitchBlade x908 will remain a standalone node until a non-stacking XEM is inserted, at which point it will initiate a topology discovery sequence and join the stack. Note that when the SwitchBlade x908 is operating as a standalone node it will not switch data around the stacking ring.

Once the switches have been physically connected to form a stack, powering all the members on automatically sets off a number of processes that enable the stack members to detect the presence of the other stack members and form themselves into a VCStack.

The Role of the Stack Master

In addition to being a member of its VCStack, the stack master manages functions such as software version control and distribution, routing processing, and network management.

Selecting the stack master

The stack members are able to automatically select which switch will become the stack master. This selection is based on two components:

1. The stack member's priority setting.
2. The stack member's MAC address.

For both components, the lower the number the higher the priority. To set the stack priority, run the stack priority command on page 103.31. Note that changes to these settings will not take effect until the next master re-election. To display these components run the show stack command on page 103.20.

The master is the switch with the lowest 'priority setting', or if the 'priority settings' are equal, the switch with the lowest MAC address will become the stack master. When a stack member is initially booted, its priority value defaults to 128. Therefore if all switches retain their defaults, then the stack master will be determined by MAC address comparison.

The stack also assigns a Stack Member-ID number to each member. This number provides a unique reference number for switches within the stack; it plays no part in selecting the stack master. The Stack Member-ID is the entity used as the first digit of the three component port identifier numbers. For example, port number 2.0.14 has the Stack Member-ID of 2.

Note

This last point is an important one to remember when using configuration scripts. You should ensure that you modify your configuration scripts to match any changes you have made to the Stack Member-ID assignments.

Note

The ability to independently set both a stack member's priority and its ID means that the stack master does not need to have an ID of `1`; although configuration is simplified by arranging for ID `1` to be the device with the lowest priority value - and thereby forcing it to be the stack master. If you create a stack using new switches, the following (simplified) process should ensure that the master member has an ID of `1`.

New switches are shipped with a Stack Member-ID of `1` and a priority of 128. If two such switches are created as a stack, the switch with the lowest MAC address will be selected to be the stack master (because all priority settings are 128). The remaining stack member device will then reboot. The stack master does not reboot and retains its Stack Member-ID of `1`.

You can change the Stack Member-ID by using either the ID select button on the XEM-STK, or by using the stack renumber command on page 103.32.

Common Stack Configuration

Once the switches have configured themselves into a VCStack, they all share the same configuration information and startup scripts.

Caution

Once the stack is formed, each stack member's configuration is associated with its Stack Member-ID number. Pressing the select button on a XEM-STK will set its switch member to have Stack Member-ID 1, and it will acquire the configuration settings assigned to that particular ID number. The other switch in the stack will then realign its Stack Member-IDs according to the stack's physical topology.

Stack Management VLAN

Managing the stack is the same as managing an individual switch. You can connect to the asynchronous console port of any stack member, or you can set an IP address on a network VLAN (for example, VLAN 1) and use SSH for remote access.

As the switches form themselves into a stack, each switch creates a common stack management VLAN and a management IP address. Both the VLAN ID and the IP address are internal entities that are used between the stacked switches, via either the stack XEM or rear panel interfaces, and therefore do not appear on the user network.

Initially the stack assigns the default VLAN tag ID of 4094 to the management VLAN, and assigns an IP address from the subnet 192.168.255.0 / 28 to this VLAN as the management IP address. Once the stack has formed, you can change both these settings. To change the VLAN ID use the stack management vlan command on page 103.30. To change the management IP address use the stack management subnet command on page 103.29. Note however, that you must keep the 28 bit subnet mask, (/28 or 255.255.255.240). Also note that because the stack's internal address mapping tables will register the management VLAN ID and the management IP address, these must be unique across the stack's internal and external network. To view the current settings for the stack management VLAN ID and IP address, use the show stack command on page 103.20.

Stack member identification

When a switch that is connected via a XEM-STK module, becomes a stack member, the numeric display on the XEM-STK indicates the switch's member ID, see the Figure 102-6 on page 102.11. If the switch is not a stack member, the XEM-STK seven-segment display will be blank. The following LEDs indicate the switch's status within the stack.

Table 102-2: Stacking LED Functions

LED	State	Meaning
Port 1 and Port 2	Green	A stacking link is established
	Amber (flashing slowly)	The link has transmission fault
	Off	The stacking link is down
Status	Green	The switch is the stack master
	Amber	The switch is a (non master) stack member
	Green (flashing)	The stack is selecting a stack master
	Off	The switch is not a stack member
Numeric ID	1 to 4	The stack member ID
	Off	The switch is not a stack member

The following figure shows the XEM-STK ports and LEDs.

Figure 102-6: XEM-STK LEDs

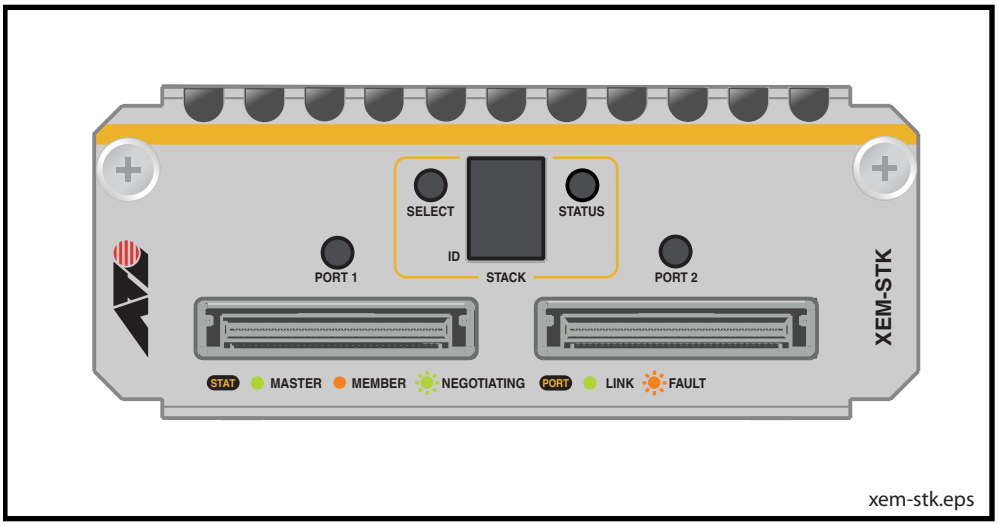


Figure 102-7: SB x908 Stacking LEDs (SwitchBlade x908)

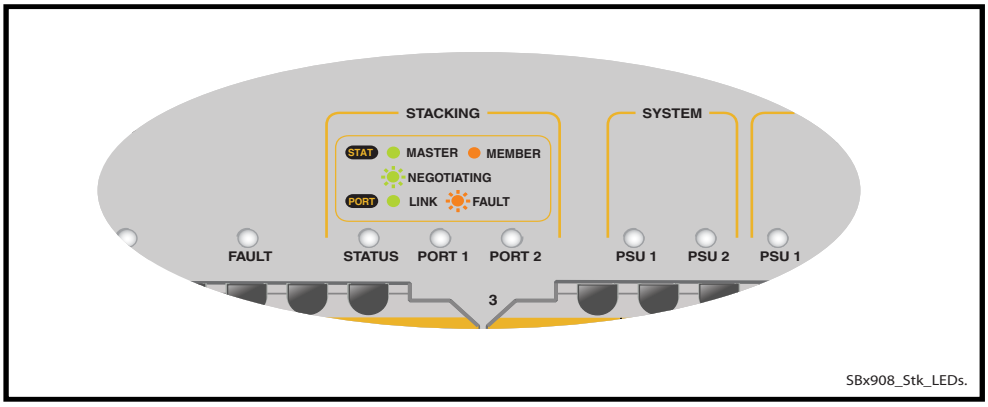

Running commands on specific stack members

In some situations, you may want to obtain information that is specific to a particular stack member. To achieve this you can use the remote-command feature. For example, to see the processes running on stack member 3, you can run the following remote-command:

```
awplus# remote-command 3 show process
```

For more information and options on this feature, see the remote-command command on page 103.8 of this manual.

Running QoS within a VCStack

In general you can apply the same principles when configuring QoS on a VCStack as you would for single switch; however there are a few specific changes that you will need to make.

Switches within a VCStack exchange their stack management information and user data over their high speed inter-stacking links. The stack management information is pre-assigned to the egress queue 7. This is the highest value queue, and (in a stacked configuration) its traffic should not be shared with any user data. However, any CoS tagging of 7 applied to the incoming data will automatically be assigned to queue 7 as it crosses the internal stacking links. You will therefore need to reconfigure your CoS to Queue settings to ensure that no user data is sent to queue 7.

To prevent this from happening, we recommend that you make appropriate changes to your queue settings (mappings) to reflect the stacking requirement previously described. For more information on this topic, see “Mapping CoS tags to traffic types” on page 60.12.

This process should include (but not be limited to) running the following command to ensure that any remaining user packets still carrying a CoS 7 tag, will be mapped to egress queue 6.

To remap priority CoS traffic to egress queue 6, run the following commands:

```
awplus# config terminal
awplus(config)# mls qos map cos-queue 7 to 6
```

Stack Member Failure and Recovery

Fixed or Virtual MAC Addressing

A VCStack operates using a single virtual MAC address. This address is configurable by using the stack virtual-mac command on page 103.38.

Enabling the stack virtual-mac

When the stack virtual-mac command is enabled, the stack uses a virtual MAC address that is either manually entered, or has been randomly selected from an allocated pool of MAC addresses. The stack will then always use this MAC address even if the stack master fails or is removed from the stack. In this situation, the new elected master will still retain the originally configured virtual MAC address.

The virtual MAC address will be used for all external ports, and VLAN interfaces, except the management VLAN. Although each individual switch in the stack retains its own native MAC address; this is only used over the stack management VLAN.

Note

If one stack member has the virtual MAC address feature enabled and another has the virtual MAC address feature disabled then they will be able to form together as a stack. From master election onwards, the stack master's virtual MAC address setting will be used by the rest of the stack.

Virtual MAC format and value

The virtual MAC address is selected from within the range 0000.cd37.0000 to 0000.cd37.0FFF. This can be considered as a MAC prefix component of 0000.cd37.0xxx.
Where xxx is called the stack virtual-chassis-ID, and has the range 000 to FFF.

Manually selected virtual address

To manually select a virtual MAC address you enable the stack virtual MAC feature by using the commands:

```
awplus# configure terminal
awplus(config)# stack virtual-mac
```

Then configure the stack virtual-chassis-id command on page 103.37 to set a stack virtual-chassis-ID of your chosen value - entered as a decimal number within the range 0 to 4095. The value 120 is used in the following example:

```
awplus# configure terminal
awplus(config)# stack virtual-chassis-id 120
```

Automatically selected virtual address

If you set the stack virtual-mac command without entering a value for the stack virtual-chassis-ID, the switch will randomly select a virtual-chassis-ID from the allocated range.

Disabling the stack virtual-mac

When the stack virtual-mac command is disabled, the stack will use the MAC address of the current Master. If the stack master fails, the stack MAC address changes to reflect the new master's MAC address. If the stack MAC address does change, ARP tables of devices on the network will update to reflect the change in MAC address via ip gratuitous-arp-link command on page 25.29.

Stack Resiliency Link

The purpose of the resiliency link is to provide the stack members with status information that allows them to detect whether the stack master is still operational after a stack failure occurs.

Using the resiliency link, a stack member can differentiate between the master suffering a power-down or a software lock-up, where the master is offline, compared with a stacking-link failure, where the master is still online but connectivity over the stacking cables has been lost.

This enables the other stack members to either operate in the fall-back Disabled Master mode, or to re-elect a new stack master. The "State Change Table" on page 102.14 shows how the stack members respond to various problems occurring on the master node.

Stack recovery states

The following state-change-table shows stack member failure conditions and recovery actions in situations where the resiliency link is present or absent.

Table 102-3: State Change Table

Event on Master Node	Reaction on Master	Reaction on Stack Member	Reaction on Stack Member
		With Resiliency Link	Without Resiliency Link
Both stack links removed	No change	Disabled Master	Re-elect master [2]
XEM-STK Removed or Faulty	No change	Disabled Master	Re-elect master [2]
Hardware reset (or fault)	Reset / offline	Re-elect master	Re-elect master [2]
Run the no stack enable command[3]	No change	Disabled Master	Not allowed Displays Error Message
Software application problem (lock-up or continual crashes)	Reboot as stack member	Re-elect master	Re-elect master
Software crash or lock-up	Frozen[4]	Re-elect master	Re-elect master
Power-down or PSU failure	Powered down	Re-elect master	Re-elect master
Event on Stack Member Node	**Reaction on Master**	**Reaction on Stack Member**	**Reaction on Stack Member**
Both stack links removed	No change	Disabled Master[1]	Re-elect master [2]
XEM-STK removed or faulty	No change	Disabled Master[1]	Re-elect master [2]
Hardware reset (or fault)	No change	Reset/offline	Reset/offline

Table 102-3: State Change Table

Run the no stack enable command[3]	No change	Disabled Master	Disabled Master
Software application failover (lock-up or continual crashes)	No change	Re-boot as backup member	Reboot as stack member
software crash or lock-up	No change	Frozen[4]	Frozen[4]
Power-down / PSU failure	No change	Powered Down	Powered down

1. When a backup member becomes the Disabled Master it will first disable all its switch ports, then activate any triggers specified with the type stack disabled-master command that have been configured.
2. The stack member assumes the role of stack master. In specific situations this condition could result in a stack containing two masters. This would present problems with network management and the control of links that were previously aggregated.
3. The following situation will apply to a switch that has been removed from the stack by the using the “no stack enable” command:
   - The switch will be unaware of further faults within the stack it was previously a member of.
   - Should this switch then be powered down, all links previously shutdown (as a result of running the no stack enable command) will remain down.
4. If the backup member’s ports are still up, this may cause downstream switches with trunked ports to operate incorrectly.

Stack Failure Recovery

If the stack master either fails, or is removed, the other stack members will re-elect a new stack master. The stack members automatically determine which of them becomes the new stack master. See the Disabled Master Monitoring (DMM) and the Disabled Master sections for more information. Alternatively, you can manually configure a trigger with the type stack disabled-master command on page 97.26 to activate on a stack member if it becomes the disabled master.

Table 102-3 shows how the stack backup members would respond to various problems occurring on the stack master stack.

Note

When VCStack is used with EPSR, the EPSR failovertime must be set to at least 5 seconds to avoid any broadcast storms during failover. Broadcast storms may occur if the switch cannot failover quickly enough before the EPSR failovertime expires. See the epsr command for further information about the EPSR failovertime. See the reboot rolling command for further information about stack failover.

Stack Separation and Recovery

Stack stubs occur when a fault results in the stack splitting into two, with one of the stack members taking on the role of stack master. Where the stack master is still active after a fault, and other stack members are not aware that the stack master is still active, the result can be two independently operating stacks, or stubs.

When two stub stacks are reconnected, a dual master situation will be detected, and the console log will display the message that a 'duplicate master' was detected. This situation results in the re-election of the stack master based upon the lowest Priority ID, or, where both members have the same Priority ID, the lowest MAC address. The 'losing' master and other prospective stack members will then reboot and join the new stack as backup stack members.

Note

Stubs are unlikely to cause network connectivity problems if a resiliency link is used.

Stack Maintenance

Adding a stack member

An unstacked switch can be added to an existing stack (hot-swapped in) with minimal impact on traffic. To do this, power down the new member switch, then connect its stacking ports and power on the switch. The switch will boot as a member of the stack.

Note

The existing Stack Member-ID and the device MAC address will have no effect on the status of the new member switch. The stack will admit the new device as an ordinary stack member and allocate it a new Stack Member-ID if its ID is one that already exists.

However, for good practice we recommend pre-configuring the new member with settings that are appropriate for when the new switch becomes a stack member. This is to avoid unexpected situations occurring when the stack is rebooted. For example, if the new member had a priority setting that was lower than 128 and all the existing stack members were configured with the default; then, when the stack is rebooted, the new member would be elected as the stack master.

Replacing a stack member

A stack member can be removed from a stack (hot-swapped out) with minimal impact on stack traffic. To do this, power-down the stack member, disconnect its XEM-STK ports. Insert the new stack member, reconnect the stacking ports and power-up the new stack member.

You can seamlessly swap a stack member switch into the stack to replace another with the same configuration. This provides a simple way to replace an out-of-service switch with minimal impact, and minimal administration requirement. You should configure the replacement switch with the same member ID as its replacement prior to inserting it into the stack.

Disabled Master

The technical term for the stack master, as displayed in the show stack command, is the active master. There is another variant of stack master called the disabled master. The disabled master will rarely, if ever, be seen because it is only used if the stack separates into two stubs. By disabling all its switchports, the disabled master avoids potentially detrimental network connectivity problems caused by having two stack masters using the same configuration. The active master's ports are unaffected by this, and it will continue to forward traffic normally.

To bring down its switchports, the disabled master actually applies the shutdown command to every switchport in its running configuration. Apart from this, the operation and 'look and feel' of a disabled master is very similar to an active master.

A disabled master trigger also allows you to specify a script to reconfigure the disabled master on the fly, should a catastrophic failure separate the stack. This is useful to configure an alternate IP address so you can still login to the disabled master via an SSH or a Telnet connection. The trigger script should use the no shutdown command to re-enable any switchports needed for an SSH or a Telnet management connection. For trigger command information see the type stack disabled-master command on page 97.26.

Note

In a stack of more than two units, several stack members could become separated from the stack master. In this case, these stack members will form a stack stub together. Only one stack member will become the disabled master. The other switches will remain as backup stack members, but their switchports will still be disabled. Status information for the stack members can be accessed by logging into the disabled master, in the same way as obtaining status information for a normal stack.

Disabled Master Monitoring (DMM)

The stack resiliency link and disabled master state offer a unique prevention of catastrophic network connectivity problems. However, when stack members become separated, the network is still left in a fragile state where the stack master no longer has the redundancy of a backup stack member. If the original stack master were to subsequently fail whilst the stack was separated, then all network connectivity would be lost if the disabled master's switchports remained shutdown.

The Disabled Master Monitoring (DMM) feature avoids this situation by continuing to monitor the status of the original stack master (the active master) via the stack resiliency link. When the DMM feature is enabled, the disabled master can detect a failure of the original stack master within a few seconds. If a failure is detected, the disabled master transitions to the active master state and automatically re-enables all its switchports. This allows traffic forwarding via the stack to continue.

For more information about the disabled master state, see the section "Disabled Master" on page 102.17. Note that a disabled master has the same configuration as an active master, but a disabled master has all its links shutdown.

Table 102-4: Stack behavior comparison

Stack behavior with DMM disabled	Stack behavior with DMM enabled
■ The VCStack breaks with the Stack Resiliency Link configured and enabled.	■ The VCStack breaks with the Stack Resiliency Link configured and enabled.
■ The separated stack member becomes a disabled master.	■ The separated stack member becomes a disabled master.
■ The disabled master does not monitor the active master.	■ The disabled master monitors the active master.
■ If the active master fails then the disabled master does not become the active master (no state transition).	■ If the active master fails then the disabled master becomes the active master (disabled to active transition).
■ No switchports are re-enabled on the disabled master. No traffic is forwarded.	■ Switchports on the disabled master are re-enabled. Traffic is still forwarded,

To enable the DMM feature, use the commands:

```
awplus# configure terminal
awplus(config)# stack disabled-master-monitoring
```

To disable the DMM feature, use the commands:

```
awplus# configure terminal
awplus(config)# no stack disabled-master-monitoring
```

To show the status of DMM on the VCStack, use the command:

```
awplus# show stack detail
```

To apply a trigger upon transition from active master state to disabled master state, use the command:

```
awplus# type stack disabled-master
```

To apply a trigger upon transition from disabled master state to active master state, use the command:

```
awplus# type stack master-fail
```

Note

A disabled master trigger allows you to specify a script to reconfigure the disabled master on the fly, should a catastrophic failure separate the stack. This is useful to configure an alternate IP address so you can still log in to the disabled master via an SSH or a Telnet connection. The trigger script should use the no shutdown command to re-enable any switchports needed for an SSH or a Telnet management connection.

Provisioning (Stack Members)

Stack member provisioning is the pre-configuration of a stack member's position ready for insertion at a later time. Provisioning enables a network administrator to pre-configure vacant stack member capacity within a VCStack, ready to be hot-swapped in at a later time. Later, when the stack member switch is physically added, its configuration is automatically applied with the minimum network disruption. Provisioning is ON by default, and cannot be disabled.

Provisioned capacity can be applied by either of the following actions:

- applying the switch provision command on page 103.39
- installing, then removing a provisionable device from its physical location, that is, a switch from its stack.

When a vacant switch is provisioned, its ports are assigned the shutdown state and are therefore not able to be activated. Applying the shutdown or no shutdown commands to a provisioned port will change only its administrative state.

Provisioned Board Classes

Provisioning introduces the concept of defined board classes. Table 102-5 on page 102.20 lists the stack member classes that have been defined for provisioning. Each board class is assigned a class and an appropriate port count. Presently no further definitions have been made for additional features such as media type, or PoE capability. This structure simplifies configuration.

Table 102-5: Provisioned Stack Member Classes

Board Classes		
Class	**Port Count**	**Bays**
x900-12	12	1
x900-24	24	2
SBx908	0	8

Provisioning limits for devices and ports

These devices have the following device and port limits.

Table 102-6: Maximum Device and Port Limits per Product Type

Device Type	Device Limit	Port Limit
SBx908	2	192
x900	2	96

Note that although the SBx908 switch can be provisioned with VCStack IDs of 1-4, and x900 switches are able to be provisioned with VCStack IDs of 1-8, both of these switch families have the limit of two switches per stack.

Applying Hardware Provisioning

As previously mentioned, provisioning is the pre-configuration of vacant (i.e. unused) device capacity ready for device insertion at a later time.

Without provisioning

On software versions prior to version 5.3.4 - trying to configure an unused port will result in the following error message:

```
awplus(config)# interface port4.0.1
% Can't find interface port4.0.1
```

With provisioning

With provisioning, you can configure stack members and their ports ready for future addition, even though they are not currently physically present:

```
awplus(config)# switch 4 provision x600-24
```

Now that the switch is provisioned within the stack—although not yet physically present—you can move on to provisionally configure the switch ports themselves. The following example sets the port speed of port 4.0.1 to be 1000 Mbps.

```
awplus(config)# interface port4.0.1
awplus(config-if)# speed 1000
```

You can apply provisional configuration to all interface related commands. However, you cannot apply provisioning where it changes the network's physical topology. For example, you can't provision a switch as stack member 3 and then later change it - while its position is still vacant - to stack member 4. In this situation, you would need to unprovision the switch, then provision it again as stack member 4.

The following example creates a provisioned configuration that shows the association of ports with a VLAN:

```
awplus# configure terminal
awplus(config)# vlan database
awplus(config-vlan)# vlan 12 state enable
awplus(config-vlan)# exit
awplus(config)# interface port2.0.1
awplus(config-if)# switchport mode access
awplus(config-if)# switchport access vlan 12
awplus(config-if)# exit
awplus(config)# interface port2.0.2-port2.0.26
awplus(config-if)# switchport mode access
```

Provisioning Error Messages

The following error messages may appear when configuring provisioning.

Table 102-7: Provisioning Error Messages (switch x [bay y] provision)

Error Message	Comment
`% Maximum port count (208) reached. No more devices can be provisioned`	Allows for a maximum eight 24 port x600 switches in a VCStack
`% Maximum stack size (%d) reached. No more switches can be provisioned`	`%d` = 2 for x908 or x900
`Switch %d must be provisioned before bays can be provisioned.`	`%d` = stack member id
`% Switch %d (%s) has 0 expansion bays.`	`%d` = stack member id `%s` = board class
`% Board class %s is incompatible with this system.`	`%s` = board class from cmd line. Indicates x600/x900 class mismatch
`% Board class %s is incompatible with existing stack members.`	`%s` = board class from cmd line. Indicates a mismatch between x900-class devices.
`% switch %d is already populated with %s.`	Indicates an attempt to provision a switch that is already present.
`% switch %d is already provisioned for %s.`	Indicates an attempt to provision a switch that is already provisioned.
`% switch %d bay %d is already populated with %s.`	Indicates an attempt to provision a XEM bay that is already populated.
`% switch %d bay %d is already provisioned for %s.`	Indicates an attempt to provision a XEM bay that is already provisioned.

Table 102-8: Provisioning Error Messages (no switch x [bay y] provision)

Error Message	Comment
`% switch %d bay %d is currently populated by %s`	You must remove hardware before unprovisioning

Removing Hardware Provisioning

Hardware capacity that has been previously provisioned *and is presently unoccupied* can be unprovisioned with the no switch provision command. This removes the provisioned configurations for hardware that has either not yet been physically added to a switch or VCStack, or has previously existed, but has been removed.

The no switch provision command will also delete any switch bay commands with the same unit number and all associated interfaces, as well as all configuration for that switch or XEM module.

You cannot unprovision hardware that is currently installed. A no switch command will not succeed if the unit/unit.bay location is currently occupied. For example:

```
awplus(config)# no switch 2 bay 8 provision
                % switch 2 bay 8 is currently populated by xem-1
```

The following example displays the output of a show stack that includes a provisioned VCStack member 3:

```
Virtual Chassis Stacking summary information
ID  Pending ID  MAC address        Priority  Status    Role
1   -           0000.cd28.5377     128       Ready     ActiveMaster
2   -           0000.cd29.95bf     128       Ready     BackupMember
3   -           0000.0000.0000     -         -         Provisioned
```

Switch ID 3 is then unprovisioned:

```
awplus(config)# no switch 3 provision
```

Run the show stack command to confirm that switch 3 has been unprovisioned.

```
awplus# show stack
```

```
Virtual Chassis Stacking summary information
ID  Pending ID  MAC address        Priority  Status    Role
1   -           0000.cd28.5377     128       Ready     ActiveMaster
2   -           0000.cd29.95bf     128       Ready     BackupMember
```

Note Ensure that you save your running configuration to your startup configuration after making any provisioning changes using copy running-config startup-config

Displaying Provisioned Configurations

In this respect the major difference associated with provisioning, is that interface configurations will still exist in the config files and will appear in show commands, even though a device itself may not be physically installed. This (provisioning) could result from device capability that has been preconfigured for future installation, or could result from the removal of an installed device.

The show running-config command includes switch commands for existing hardware, plus all non-existent, but provisioned, hardware. The following example output of the show running-config command illustrates how provisioned and existing hardware is displayed.

Figure 102-8: Sample display of existing and provisioned show output

```
sh running-config
.
.
switch 1 provision x908
switch 1 bay 1 provision xem-12
switch 1 bay 2 provision xem-12
switch 1 bay 3 provision xem-12
switch 1 bay 5 provision xem-12
switch 1 bay 7 provision xem-1
switch 1 bay 8 provision xem-1
switch 2 provision x908
switch 2 bay 1 provision xem-12
switch 2 bay 2 provision xem-12
switch 2 bay 3 provision xem-1
switch 2 bay 8 provision xem-1
!
interface port1.1.1-1.1.12
 switchport
 switchport mode access
!
interface port1.2.1-1.2.12
 switchport
 switchport mode access
!
interface port1.3.1-1.3.12
 switchport
 switchport mode access
.
.
.end
```

Displaying provisioned hardware status

The status, present or provisioned, appears in monitoring commands such as the show interface brief command. The following sample output from the show interface brief command shows the provisioning status of two configured stack members.

Figure 102-9: Sample **show interface brief** output showing hardware provisioning status

```
awplus#show interface brief
Interface              Status          Protocol
port2.0.24             admin up        down
port3.0.1              admin up        provisioned
port3.0.2              admin up        provisioned
```

A more detailed inspection of the provisioned port 2.8.1 is shown below. Note that the MAC address of 0000.0000.0000, which is the value applied as a placeholder for all provisioned ports. Also note that although the port is in the link DOWN state its administrative state of UP PROVISIONED means that it can be further configured. For example, it can be associated with a VLAN, or added to a link aggregation group etc.

Figure 102-10: Sample display showing provisioning status of a specific port

```
Interface port2.8.1
  Scope: both
  Link is DOWN, administrative state is UP PROVISIONED
  Thrash-limiting
    Status Unknown, Action learn-disable, Timeout 1(s)
  Hardware is Ethernet, address is 0000.0000.0000
  index 6801 metric 1 mtu 1500 mru 1522
  <BROADCAST,MULTICAST>
  VRF Binding: Not bound
  SNMP link-status traps: Disabled
    input packets 0, bytes 0, dropped 0, multicast packets 0
    output packets 0, bytes 0, multicast packets 0 broadcast
pks0
```

Provisioning and Configuration Management

A benefit of provisioning is configuration settings are no longer dependant on the existence of hardware devices. When a device is removed, all the interfaces for that device are shutdown and its provisioning status is set. This means that you can add or remove physical hardware without affecting your network interfaces. Of course when ports go down (i.e. are physically removed) there will be other changes to network configuration, as protocols may re-converge or, for example, routes may be removed etc.

Switches within a VCStack (or XEMs within a switch) can be hot-swapped without the need for reconfiguration.

The configuration of a newly inserted device that matches the provisioned board-class is achieved on a best-effort basis. For example inserting a non-POE switch into a stack member location configured for PoE will result in the failure of the PoE configuration commands.

Take care that your provisioned configurations, match with the type of hardware that you plan to install. For example, the XEM-12 configuration shown below has the port speed set for one of its ports:

```
awplus(config)# switch 2 bay 4 provision xem-12
awplus(config)# int port2.4.1
awplus(config-if)# speed 10
```

This will be fine if a XEM-12T is installed; however installing a XEM-12S (a device that cannot run its ports at 10 Mbps) would result in an error condition.

Software Version Auto Synchronization

Introduction

Different software releases have functional and operational differences between them. To maintain consistent behavior across the stack, all new member switches must be running the same software release before they can fully join the stack.

Manually upgrading the software release of each new stack member that joins a stack would be a cumbersome process. The VCStack software version auto synchronization feature automates this process by ensuring the same software release is used on all stack members, and automatically upgrading stack members where required.

How auto synchronization works

Software version comparison

When the stack is formed, it elects one of its switches to become the master. The software release running on the stack master will then become the software version used throughout the stack. After a master is elected, all the stack members compare their current software version with the version that is running on the stack master.

If the comparison process detects differences between software versions, the software version synchronization feature will automatically copy the master's software release onto the appropriate stack members. Once the software release has successfully been copied, this version will become the boot software for that particular stack member, which will then reboot in order to load the new software release.

If a software version running on a stack member is incompatible with that running on the master, and software-auto-synchronization is turned off, then that switch will be removed as a stack member. See stack software-auto-synchronize command on page 103.36.

From release 5.4.1 onwards, when auto-synchronization upgrades a stack member, the member's current running software will be set as the backup software release. If there are any problems loading the new software, then the backup software release will be used to recover.

If the stack member does not have enough free Flash memory space for the new release, then the new release will replace up to two older release files in Flash memory, which is determined by software build dates of the older release files. The oldest release files are replaced first.

Auto synchronization limitations

Because the stack master's software version gets applied to the rest of the stack, care must be taken to ensure the correct switch is elected master. If the master is running an older software release, then software version auto synchronization may actually downgrade the software releases running on other stack members. For configuring which stack member becomes the master, see the stack priority command on page 103.31.

Software auto-synchronization will not work if stack members are booting using either one-off boot or from TFTP or ymodem. In these situations, any stack members running different software will boot as standalone devices.

If software-auto-synchronization is configured as off for a stack member that is running a different software release to the master, by applying the command, no stack software-auto-synchronize, then that switch will boot as a standalone device. For more information, see the stack software-auto-synchronize command on page 103.36.

Incompatible software releases

The auto-synchronization feature will not always work if there have been significant VCStack or system changes between the two different software releases. The VCStack discovery of other stack members uses an internal 'stack S/W version' to detect compatibility between builds.

If the VCStack software between two stack members is incompatible, the software auto-synchronization feature will not work. Instead, a “incompatible stack S/W version” log message will be displayed and both stack members will boot as standalone devices. This is an undesirable situation because both devices may load the same configuration file, which could cause network conflicts. In order to avoid this situation when upgrading the stack to a new major release, ensure the 'boot system' command succeeds.

In general, the software-auto-synchronize feature will always work between maintenance releases, such as between 5.3.2-0.1 and 5.3.2-0.2, but may not work between major releases that have new VCStack features, such as between 5.2.2-0.9 and 5.3.2-0.2.

Upgrading stack software reliably

When upgrading a stack to a new software release, the boot system command on page 7.7 will automatically synchronize the new software release across all stack members. If there is insufficient file space on a backup member, the boot system command has an interactive mode that prompts you to delete old releases to free up file space. However, if you choose not to delete any release files, or if Flash space is taken up with other types of files, then the boot system command can fail to set the preferred release on the backup member. If this situation occurs, it is recommended to manually free up file space on the stack member and then reenter the boot system command.

If you are unsure which files to delete, the following process may assist you.

```
awplus# remote-login 2
awplus-2# enable
awplus-2# dir
```

Use the remote-login command to login to the backup member with insufficient free file space, in this example member-2.

Look for any .rel (release) files, .jar (GUI), or .tgz and .gz (diagnostic) files that are no longer needed and use the delete command to remove them from the back-up member's file system.

Alternatively, you can use the file system commands directly from the master's console prompt using the filepath of the backup member's Flash. Substitute awplus for the hostname in the configuration, and use awplus-3 for stack member-3, and so on.

```
dir awplus-2/flash:*
delete awplus-2/flash:/x900-5.4.2.rel
```

Stack License Management

You can manage feature licenses across all members of a stack concurrently. This means that a feature license for a product family, which is defined as a set of devices containing variants of the same product type that are able to be stacked together, can be enabled or disabled on all members of the stack at the same time. Previously, you had to configure each member of the stack individually.

Feature licenses across a stack can be managed either via the CLI with the license member command or via SNMP using the AT-LICENSE-MIB Enterprise MIB.

The stack does not have to be restarted when a feature license is enabled or disabled. When a new feature license is enabled across the stack some protocol modules may need to be restarted before the license is activated. A warning is given about the need to restart the protocol modules and a “y/n” prompt is given to proceed with the license installation. If SNMP is used to enable a feature license, the affected protocol modules are restarted automatically.

When you remove a feature license across all members of the stack via the CLI you are prompted for confirmation before the license is disabled. If SNMP is used to disable a feature license no warning is generated.

To maintain consistent behavior across the stack, all member switches should have the same feature licenses enabled. However, you can enable or disable a feature license on a single stack member if required. Note that doing so could result in the stack failing to operate correctly or in the stack separating. If you enable or disable a feature license on a single stack member via the CLI a warning message is generated. A warning message is not generated if you manage the stack via SNMP.

A license key can be purchased that includes a limit on the number of switches that it can be applied to. If the license is applied to a stack that has more members than the license is valid for via the CLI, a warning message is generated and the event is logged.

For feature licenses, contact your authorized distributor or reseller. If a license key expires or a proper key is not installed, some software features will not be available.

Note

See the AlliedWare Plus™ datasheet for a list of current feature licenses available by product, and the AlliedWare Plus™ How To notes for information on obtaining them.

To enable a feature license on all stack members, use the command:

```
awplus# license <name> <key> member all
```

To enable a feature license on a specific stack member, use the command:

```
awplus#  license <name> <key> member <1-8>
```

To disable a feature license on all stack members, use the command:

```
awplus# no license <name> member all
```

To disable a feature license on a single stack member, use the command:

```
awplus# no license <name> member <1-8>
```

To display detailed information about feature licenses on all stack members, use the command:

```
awplus# show license [<name>] member all
```

To display brief information about feature licenses on all stack members, use the command:

```
awplus# show license [<name>] brief member all
```

To display detailed information about feature licenses on a single stack member, use the command:

```
awplus# show license [<name>] member <1-8>
```

To display brief information about feature licenses on a single stack member, use the command:

```
awplus# show license [<name>] brief member <1-8>
```

Chapter 103: Stacking Commands

Introduction 103.2
Command List 103.3
clear counter stack 103.3

switch provision 103.39
switchport resiliencylink 103.40
undebug stack 103.40

Introduction

This chapter provides an alphabetized reference for each of the Stacking commands. Also note the following stacking trigger commands that are documented in the Triggers chapter:

type stack disabled-master command on page 97.26
type stack master-fail command on page 97.27
type stack member command on page 97.27
type stack link command on page 97.28

In addition to the stacking commands shown in this chapter, stacking content also exists in the following commands:

hostname command on page 8.18
reload command and reboot command on page 8.23
show cpu command on page 8.27
show cpu history command on page 8.31
show exception log command on page 10.39
show file systems command on page 7.33
show memory command on page 8.39
show memory allocations command on page 8.41
show memory history command on page 8.44
show process command on page 8.49
show system command on page 8.53

Command List

clear counter stack

This command clears all VCStack counters for all stack members.

Syntax `clear counter stack`

Mode Privileged Exec

Example To clear all VC Stack counters:

```
awplus# clear counter stack
```

Related Commands show counter stack

debug stack

This command enables the Virtual Chassis Stacking (VCStack) debugging facilities.

Syntax

```
debug stack [link|topology|trace]
no debug stack [link|topology|trace]
```

Parameter	Description
`link`	Stacking neighbor discovery events on stack links.
`topology`	Stacking topology discovery messages.
`trace`	Notable stacking events.

Default Stack trace debugging is enabled.

Mode Privileged Exec and Global Configuration

Usage This command enables the Virtual Chassis Stacking (VCStack) debugging facilities. It can only be entered on the stack master.

The command displays debug information about the stacked devices. If no parameter is specified, all the stack debugging information will be displayed, including link events, topology discovery messages and all notable stacking events. If link parameter is specified, only the link events debugging information will be displayed.

Examples To enable debugging, enter the following command on the stack master:

```
awplus# debug stack
```

To enable link debugging, enter the following command on the stack master:

```
awplus# debug stack link
```

To enable topology discovery debugging, enter the following command on the stack master:

```
awplus# debug stack topology
```

To enable stack trace debugging, enter the following command on the stack master:

```
awplus# debug stack trace
```

Related Commands undebug stack

license member

This command enables a licensed software feature set on either a specific stack member, or on all stack members.

Use the no variant of this command to disable a licensed software feature set on either a specific stack member, or on all stack members provided the specified license has the same set of features on each stack member.

For feature licenses, contact your authorized distributor or reseller. If a license key expires or a proper key is not installed, some software features will not be available.

Note

See the AlliedWare Plus™ datasheet for a list of current feature licenses available by product, and the AlliedWare Plus™ How To notes for information on obtaining them.

Syntax

```
license <name> <key> member [<1-8>|all]
no license <name> member [<1-8>|all]
```

Parameter	Description
<name>	A unique user-defined name for the license. To determine names already in use, use the show license member command.
<key>	The encrypted license key to enable this set of software features.
<1-8>	The ID of the stack member on which the license is to be installed.
all	All stack members.

Mode Privileged Exec

Usage When a licensed software feature is not enabled on all devices within a stack it will result in a mismatch between licenses across the stack, possibly resulting in the stack failing to operate correctly. A warning message is generated if you only specify a single stack member when operating in a stacked configuration:

```
% Warning: licensed features do not match on all stack members.
To prevent the risk of an outage, please resolve.
```

You can obtain a license key that includes a limit on the number of switches that it can be applied to. If the license is applied to a stack that has more members than the license is valid for a warning message is generated and the event is logged.

Examples To enable the license `name1` with the key `12345678ABCDE123456789ABCDE` on all stack members, use the command:

```
awplus# license name1 12345678ABCDE123456789ABCDE member all
```

To remove the license `name1` from all stack members, use the command:

```
awplus# no license name1 member all
```

Validation Command show license member

Related Commands license
show license

reboot rolling

This command reboots a stack in a rolling sequence to minimize downtime.

The stack master is rebooted, causing the remaining stack members to failover and elect a new master. The rebooted unit remains separate from the remaining stack and boots up as a stand-alone unit. Once the rebooted unit has finished running its configuration and has brought its ports up, it reboots the remaining stack members in the order of their stack member IDs.

Syntax `reboot rolling`

Mode Privileged Exec

Usage If you are upgrading to a new software version, the new version must also support rollling reboot.

Note When VCStack is used with EPSR, the EPSR failovertime must be set to at least 5 seconds to avoid any broadcast storms during failover. Broadcast storms may occur if the switch cannot failover quickly enough before the EPSR failovertime expires. For further information about EPSR failovertime, see the epsr command on page 82.3.

Examples To rolling reboot the stack, use the following commands:

```
awplus# reboot rolling

Continue the rolling reboot of the stack? (y/n):
```

After running this command, the stack master will reboot immediately with the configuration file settings. The remaining stack members will then reboot once the master has finished re-configuring.

```
Continue the rolling reboot of the stack? (y/n):

awplus# y
```

Related Commands boot system
epsr

reload rolling

This command performs the same function as the reboot rolling command on page 103.7.

remote-command

This command executes a number of host-directed commands that are specific to stack members.

Syntax

```
remote-command <1-8>
   show {cpu|counter|exception|file|memory|process|stack|system}

remote-command <1-8>
   clear counter stack
```

Parameter	Description
<1-8>	The ID of the stack member where the command should be executed on.
`clear counter stack`	Can be used on a VCStack master to remotely run the clear counter stack command on page 103.3.
`cpu`	Selects the show cpu command on page 8.27.
`counter`	Selects the show counter stack command on page 103.11.
`exception`	Selects the show exception log command on page 10.39.
`file`	Selects the show file command on page 7.32.
`memory`	Selects the show memory command on page 8.39.
`process`	Selects the show process command on page 8.49.
`stack`	Selects the show stack command on page 103.20.
`system`	Selects the show system command on page 8.53.
`show CPU history`	Selects the show cpu history command on page 8.31.
`show CPU sort pri`	Selects the show cpu command on page 8.27 to run with the parameters sort and pri selected.
`show CPU sort runtime`	Selects the show cpu command on page 8.27 to run with the parameters sort and runtime selected.
`show CPU sort sleep`	Selects the show cpu command on page 8.27 to run with the parameters sort and pri selected.
`show CPU sort thrds`	Selects the show cpu command on page 8.27 to run with the parameters sort and thrds selected.
`show exception log`	Selects the show exception log command on page 10.39.
`show file systems`	Selects the show file systems command on page 7.33.

Parameter(cont.)	Description(cont.)
`show log permanent`	Selects the show file systems command on page 7.33.
`show log permanent`	Selects the show log permanent command on page 10.45.
`show log permanent tail`	Selects the tail parameter of the show log permanent command on page 10.45.
`show memory`	Selects the show memory command on page 8.39.
`show memory history`	Selects the history parameter of the show memory command on page 8.39.
`show memory sort peak`	Selects the sort and peak parameters of the show memory command on page 8.39.
`show memory sort size`	Selects the sort and size parameters of the show memory command on page 8.39.
`show memory sort stk`	Selects the sort and stk parameters of the show memory command on page 8.39.
`show process`	Selects the show process command on page 8.49.
`show process sort cpu`	Selects the sort and cpu parameters of the show process command on page 8.49.
`show process sort mem`	Selects the sort and mem parameters of the show process command on page 8.49.
`show stack`	Selects the show stack command on page 103.20.
`show stack detail`	Selects the details parameter of the show stack command on page 103.20.
`show system`	Selects the details parameter of the show stack command on page 103.20.
`show system environment`	Selects the show system command on page 8.53.
`show system pluggable`	Selects the pluggable parameter of the show system command on page 8.53.
`show system serialnumber`	Selects the serialnumber parameter of the show system command on page 8.53.

Default None

Mode Privileged Exec, and can be also be used in the same mode as the equivalent non-remote command.

Usage This command is used only from the master to execute a command subset that is specific to stack members. If the member ID is not used by any current stack member, the command will be rejected.

Example To execute the show system command on stack member 2, use the command:

```
awplus# remote-command 2 show system
```

remote-login

This command is used only on the master in order to log onto the CLI of another stack member. In most respects the result of this similar to being logged into the stack master. Configuration commands are still applied to all stack members, but show commands, and commands that access the file system are executed locally.

The specific output obtained will vary greatly depending on the show command chosen.

Syntax `remote-login (<1-8>`

Parameter	Description
<1-8>	The specific stack member whose CLI is to be accessed.

Mode Privileged Exec

Usage Note that some commands such as ping or telnet are not available when the remote-login is used.

Example To log onto stack member 2, use the following command:

```
awplus# remote-login 2
```

To return to the command prompt on the master stack member, type exit.

show counter stack

Use this command to display Virtual Chassis Stack (VCStack) related counter information.

Syntax `show counter stack`

Default All counters are reset when the stack member is rebooted.

Mode User Exec and Privileged Exec

Usage If this command is entered on the stack master, it will display all the stacking counter information for every stack member.

When used as a host-directed command, it will display only the stacking counter information for the specific stack member.

Examples To display the stacking counter information about the whole stack, use the following command on the stack master.

```
awplus# show counter stack
```

To display the stacking counter information about stack member 2, use the command:.

```
awplus# remote-command 2 show counter stack
```

Figure 103-1: Example output from the **show counter stack** command

Stack member 2:

-- Output repeated for other stack members - details not shown--
```

Table 103-1: Parameters in the output of the **show counter stack** command

Parameters	Description
Topology Event Counters	
Units joined	Number of times that the stack acquires a member.
Units left	Number of times that the stack loses a member.
Links up	Number of times that a stack link is up in the stack.
Links down	Number of times that a stack link is down in the stack.
ID conflict	Number of times that stack member ID conflicts.
Master conflict	Number of times that stack master conflict occurs.
Master failover	Number of times that stack master fails.

Table 103-1: Parameters in the output of the **show counter stack** command(cont.)

Parameters	Description
`Master elected`	Number of times that stack master is elected.
`Master discovered`	Number of times that stack master is discovered.
`SW autoupgrades`	Number of times that the software in the stack members are auto upgraded.
`Stack port counters`	
`Link up`	Number of times that this unit's physical stack link has come up.
`Link down`	Number of times that this unit's physical stack link has come down.
`Nbr re-init`	Number of times that the neighbor is detected as having reinitialised.
`Nbr incompatible`	Number of times that the neighbor is detected as incompatible.
`Nbr 2way comms`	Number of times that the neighbor is in two way communication. status.
`Nbr full comms`	Number of times that the neighbor is in full communication status.
`Topology message counters`	
`Total`	Number of total topology messages.
`Hellos`	Number of hello messages.
`Topology DB`	Number of topology database messages.
`Topology update`	Number of topology database update messages.
`Link event`	Number of link events messages.
`Reinitialise`	Number of reinitialise messages.
`1-hop transport`	Number of 1-hop transport messages.
`Layer-2 transport`	Number of layer 2 transport messages.
`Link event`	Number of link events messages.
`Reinitialise`	Number of reinitialise messages.
`1-hop transport`	Number of 1-hop transport messages.
`Layer-2 transport`	Number of layer 2 transport messages.
`Topology error counters`	Reasons why a neighboring unit could not join the stack.
`Version unsupported`	Number of stack software version unsupported errors.
`Product unsupported`	Number of Product unsupported errors.
`XEM unsupported`	Number of XEM unsupported errors.
`Too many units`	Number of too may units errors.

Table 103-1: Parameters in the output of the **show counter stack** command(cont.)

Parameters	Description
`Invalid messages`	Number of invalid messages.
`Health status good`	The number of times that the resiliency link has successfully carried healthchecks following a failure at startup.
`Health status bad`	The number of times that the resiliency link healthcheck has timed out. A timeout occurs when a backup stack member detects a delay greater than two seconds between healthcheck messages received.
`Rx`	The total number of healthcheck messages that a stack member has received from the stack master.
`Rx Error`	The total number of invalid healthcheck messages that have been received from the master. This message is not applicable to the stack master.

Related Commands show stack

show debugging stack

This command shows which debugging modes are currently enabled for virtual chassis stacking.

Syntax `show debugging stack`

Mode User Exec and Privileged Exec

Usage To display the stack debugging mode status, use the command:

```
awplus# show debugging stack
```

Figure 103-2: Example output from the show debugging stack command

```
Virtual Chassis Stacking debugging status:
  VCS link debugging is on
  VCS topology debugging is on
  VCS trace debugging is on
```

Related Commands debug stack
remote-command

show license member

Use this command to display information about either a specific software license, or all software feature licenses enabled on either a specific stack member or all stack members.

Syntax `show license [<name>] [brief] member [<1-8>|all]`

Parameter	Description
`<name>`	The name of the license to show information about.
`brief`	Display a brief summary of license information.
`<1-8>`	The ID of the stack member to show information about.
`all`	Display information about all stack members.

Mode User Exec and Privileged Exec

Examples To display a brief summary of information about all enabled licenses on stack member 2, use the command:

```
awplus# show license brief member 2
```

To display full information about all enabled licenses on all stack members, use the command:

```
awplus# show license member all
```

To display full information about the license `name1` on all stack members, use the command:

```
awplus# show license name1 member all
```

Output Figure 103-3: Example output from the **show license member** command

```
awplus#show license index member 1
Stack Member 1
OEM Territory: ATKK
Software Feature Licenses
-----------------------------------------------------------------
Index                          : 0
License name                   : Base License
Customer name                  : Base License
Quantity of licenses           : 1
Type of license                : Full
License issue date             : 07-Jul-2000
License expiry date            : N/A
Features included              : OSPF-64, VRRP
```

Table 103-2: Parameters in the output of the **show license member** command

Parameter	Description
Index	Index identifying entry.
License name	Name of the license key bundle (case-sensitive).
Customer name	Customer name.
Quantity of licenses	Quantity of licensed installations.
Type of license	Full or Temporary.
License issue date	Date the license was generated.
License expiry date	Expiry date for temporary license.
Features included	List of features included in the license.

Figure 103-4: Example output from the **show license brief member <*1-8*>** command

```
awplus#show license brief member 2

show license

show running-config stack

Use this command to display the running system information specific to the virtual chassis stack.

```
show running-config stack
```

Mode Privileged Exec and Global Configuration

Example To display the stacking running configuration information, use the command:

```
awplus# show running-config stack
```

Output Figure 103-5: Example output from the **show running-config stack** command

```
stack management vlan 4000
stack management subnet 192.168.0.0
stack resiliencylink eth0
no stack 1 software-auto-synchronize
no stack 4 software-auto-synchronize
stack 2 priority 0
```

Related Commands remote-command
show running-config

show provisioning (stack-member)

Use this command to display the provisioning status of all installed or provisioned hardware. Provisioning is the preconfiguration necessary to accommodate future connection of hardware items such as a switch.

Syntax `show provisioning`

Mode User Exec and Privileged Exec

Example To show provisioning, use the following command:

```
awplus# show provisioning
```

Output Figure 103-6: Example output from the **show provisioning** command

```
Switch provisioning summary information

ID  Board class Status
1.0 x908        Hardware present
1.1 xem-12      Provisioned
1.4 xem-2       Hardware present
1.5 xem-1       Provisioned
```

Table 103-4: Parameters in the output of the **show provisioning** command

Parameter	Description
`ID`	The unit.bay-location of the hardware provision.
`Board class`	The hardware type.
`Status`	The provisioned state: ■ Hardware Present means that the hardware is currently installed in the stack. ■ Provisioned means that although the hardware is not currently installed; the stack is preconfigured ready to accept the hardware installation.

Related Commands show stack
switch provision

show stack

Use this command to display information about current stack members.

Syntax `show stack [detail]`

Parameter	Description
`detail`	Display detailed stacking information.

Default Display summary information only.

Mode User Exec and Privileged Exec

Usage This command displays information about current stack members. If the detail parameter is specified, additional information will be displayed for each stack member. By default, only summary information is displayed.

This command can be entered on any stack member as a host-directed command. However, all stack members display the same stacking information.

Examples To display basic information about the stack, use the command:

```
awplus# show stack
```

To display the detailed stacking information about the whole stack:

```
awplus# show stack detail
```

Output Figure 103-7: Example output from the **show stack** command

```
Virtual Chassis Stacking summary information

ID  Pending ID  MAC address       Priority  Status  Role
1   -           0000.cd28.07e1    128       Ready   Active Master
2   -           0015.77c2.4d44    128       Ready   Backup Member

Operational Status                Normal operation
Stack MAC address                 0000.cd28.07e1
```

Table 103-5: Parameters in the output from the **show stack** command

Parameter	Description
`ID`	Stack member ID
`MAC address`	Stack member MAC address
`Priority`	Stack member master election priority (between 0 and 255) Note that the lowest number has the highest priority.
`Role`	Stack member's role in the stack, this can be one of: ■ Active Master. ■ Disabled Master (The temporary master when there is a communication break within the stack, but communication still exists across the resiliency link. In this state all switch ports within the stack are disabled by default, but a different configuration can be run by a "type stack disabled-master" trigger). ■ Backup Member (A device other than the stack master). ■ Provisioned - Indicates that the stack position is provisionally configured, i.e. ready to accept a particular switch type into the stack.

S/W version auto synchronization        On
Resiliency link status                  Successful
Stack port 2.1.1 status                 Learnt neighbor 1
Stack port 2.1.2 status                 Learnt neighbor 1
```

Table 103-6: Parameters in the output from the **show stack detail** command

Parameter	Description
`Auto upgrade`	Whether the software-auto-configuration feature is turned on, or off.
`Host name`	The host name of the stack member.
`ID`	The stack member ID.
`Last Role Change`	The date and time with the stack member last changed its role in the stack.
`MAC address`	Stack member MAC address.
`Management VLAN ID`	The VLAN ID currently used for stack management: Default is 4094.
`Management VLAN subnet address`	The current stacking management VLAN subnet address.
`Virtual Chassis ID`	The Virtual Chassis ID determines the last 12 bits of the Virtual MAC address: `0000.cd37.0xxx`
`Virtual MAC Address`	The Virtual MAC address of the stack.
`Disabled Master Monitoring`	The current Disabled Master Monitoring status. This can be: ■ Enabled ■ Disabled ■ Inactive
`Operational Status`	The status of the stack - either enabled or disabled.
`Stack Status`	The stack's overall status. Note that a warning is issued if the stack is not connected in a standard ring topology.
`Pending ID`	The pending stack member ID. This can be changed by the stack renumber command on page 103.32. If there is no pending ID, the "–" symbol will display.
`Stack port status`	The status of the stack port. This can be: ■ Down - neighbor incompatible ■ Discovering neighbor, or Learnt neighbor *<neighbor member = ""id>=""">*
`Priority`	Stack member master election priority (between 1 and 255) Note that the lowest number has the highest priority.
`Product Type`	Stack member product type. For example, switchblade x908.
`Switchblade x908 Stacking Ports`	This shows the status of the chassis rear stacking port, only on the SwitchBlade x908.
`Provisioned`	Indicates that the stack position is provisionally configured, i.e. ready to accept a particular switch type into the stack.

Table 103-6: Parameters in the output from the **show stack detail** command(cont.)

Parameter	Description
`Resiliency link status`	The current status of the resiliency link. The status can be one of: ■ Not configured, (Master or Member). ■ Configured (Master only). ■ Successful: Successfully receiving healthchecks from the Active Master. ■ Failed (Member only): Not receiving any healthchecks from the Active Master. ■ Stopped: The resiliency link is configured, but is inactive. This may occur in a Disabled Master stack, for example if the Disabled Master Monitoring feature is not used.
`Role`	Stack member's role in the stack, this can be one of: ■ Active Master. ■ Disabled Master (The temporary master when there is a communication break within the stack, but communication still exists across the resiliency link. In this state all switch ports within the stack are disabled by default, but a different configuration can be run by a "type stack disabled-master" trigger command). ■ Backup Member (a device other than the stack master). ■ Discovering - joining the stack.
`Status`	Indicates how readily a stack member can take over as master if the current stack master were to fail. ■ Init - the stack member is completing the startup initialization. ■ Syncing - the stack member is synchronizing state information with the stack master following startup. ■ Ready - the stack member is fully synchronized with the current master and is ready to take over immediately.

show stack resiliencylink

Use this command to display information about the current status of the resiliency-link across the members of the stack.

```
show stack resiliencylink
```

Mode User Exec and Privileged Exec

Example To display information about the current status of the resiliency-link across the stack members, use the command:

```
awplus# show stack resiliencylink
```

Output Figure 103-9: Example output from the **show stack resiliencylink** command

```
awplus(config)# show stack resiliencylink
Stack member 1:
---------------------------------------------------------
Status                          Configured
Interface                       vlan4093
Interface state                 UP
Resiliency-link port(s)         port1.2.11

Stack member 2:
---------------------------------------------------------
Status                          Successful
Interface                       vlan4093
Interface state                 UP
Resiliency-link port(s)         port2.2.11
```

Table 103-7: Parameters in the output of the **show stack resiliencylink** command

Parameter	Description
`Status`	The current status of the stack member's resiliency link. Can be one of: ■ Not configured, (Master or Member). ■ Configured (Master only). ■ Successful: Successfully receiving healthchecks from the Active Master. ■ Failed (Member only): Not receiving any healthchecks from the Active Master. ■ Stopped: The resiliency link is configured, but is inactive. This may occur in a Disabled Master stack, for example if the Disabled Master Monitoring feature is not used.
`Interface`	The name of the eth0 or VLAN interface that is connected to the resiliency link.
`Interface state`	The current status of the interface. Can be one of: ■ Up ■ Down
`Resiliency-link port(s)`	The switch port(s) the resiliency link is connected to.

switchport resiliencylink

stack disabled-master-monitoring

This command enables the Disabled Master Monitoring (DMM) feature. If a stack member becomes a disabled master, the DMM feature will use the stack resiliency link to continue monitoring the health of the separated stack master.

Use the no variant of this command to disable the DMM feature.

Syntax

```
stack disabled-master-monitoring
no stack disabled-master-monitoring
```

Default By default, Disabled Master Monitoring is enabled. However, it only operates if there is a resiliency link.

Mode Global Configuration

Usage This command enables additional stack resiliency link functionality, which is used if a stack separation occurs. For DDM to operate, a resiliency link must also be configured (stack resiliencylink command on page 103.34). A stack separation could result in a stack member becoming a disabled master, which has the configuration as a normal stack master except that all its switchports are shutdown.

For more information about the disabled master state, see "Disabled Master" on page 102.17.

When the DMM feature is enabled, the disabled master will continue to monitor the health of the original stack master over the stack resiliency link connection. If the original stack master were to fail, when the DMM feature is enabled, then the disabled master will detect this and will automatically re-enable its switchports. This ensures that the stack will continue to pass network traffic, even if a catastrophic stack failure occurs.

For more information about the DMM feature when the stack member is a disabled master, see "Disabled Master Monitoring (DMM)" on page 102.18.

Examples To enable the DMM feature, use the following commands:

```
awplus# configure terminal
awplus(config)# stack disabled-master-monitoring
```

To disable the DMM feature, use the following commands:

```
awplus# configure terminal
awplus(config)# no stack disabled-master-monitoring
```

type stack master-fail

stack enable

This command is used on a stackable stand-alone switch to manually turn on the virtual chassis stacking feature and XEM-STK links.

By default, the VCStack feature starts automatically at the device start-up when XEM-STK is detected.

This command is run on a switch that has previously been removed from the stack (by using the no variant of this command) in order to return its stack membership member.

The no variant of this command will remove a selected stack member switch from the virtual chassis stack.

Syntax

```
stack enable

no stack <1-8> enable
```

Mode Global Configuration

Usage Running the no variant of this command will remove the selected stack member from the VCStack. At this point the removed member will act as a stand-alone master and will disable all of its ports. The switch can then only be accessed via its console port.

To return the switch to stack membership, you first run the stack enable command. Note that to do this you must direct connectivity via the console port. Then you must run the reboot command on page 8.23. This will reboot the switch and it will re-join the stack as an ordinary member.

If the switch was previously the stack master, you might want to return it to its original stack master status. To do this you must run the reboot command on page 8.23 again. This time—because the switch is now a stack member—the command will reboot the whole stack and generate the master election processes. See the following notes.

Note the following conditions of applying the no stack <*1-8*> enable command:

- If the specified member is a stack master, and no resiliency link is configured, this command will be rejected.
- If the specified member ID is not used by any current stack member, the command will be rejected.

Caution

Disabling a stack member can significantly degrade the throughput capability of the stack.

Example To turn on stacking on a stackable stand-alone unit, use the command:

```
awplus# configure terminal
awplus(config)# stack enable
```

Related Commands reboot

stack fallback-config (Disabled)

This command has been disabled. To simplify stack recovery, stub reconfiguration is now achieved by using a trigger that is generated by the type stack disabled-master command on page 97.26.

This command is used to set the fallback configuration file to use if the stack splits into stubs due to connectivity failures.

Syntax

```
stack fallback-config <url>

no stack fallback-config
```

Parameter	Description
<url>	The URL of the stack fallback configuration file.

Mode Global Configuration

Usage This command is used to select the fallback configuration file to be used if a connectivity fault causes the stack splits into stubs. The stack splits into stubs when:

- connectivity is lost between stack members and the stack master across the inter-stack connection.
- the stack master is assumed to be still online, but is no longer reachable by all stack members.

In a stub scenario, the remaining stack members cannot use the same stack configuration, because this will result in potential configuration conflicts, particularly where static channels terminate on different stacking units.

The fallback-config allows the remaining stack members to continue processing network traffic to some degree, without clashing with the existing stack's configuration. Configuring a fallback-configuration also means that the isolated stub members can still be accessible via a management IP address, and so can be re-configured on the fly.

Caution

It is important that any ports that are configured as trunked ports across master and stack members are disabled at their stack member termination when operating in the fallback configuration. Otherwise, the trunked ports will not function correctly on the switch that is connected downstream.

Example

```
awplus# configure terminal
awplus(config)# stack fallback-config flash:/stk_stb.conf
```

Related Commands stack resiliencylink

stack management subnet

This command configures the stack's VLAN subnet management address.

Use the no variant of this command to reset the stack's VLAN subnet management address back to the default address and mask (192.168.255.0/28).

Syntax

```
stack management subnet <ip-address>
no stack management subnet
```

Parameter	Description
<ip-address>	The new subnet address for VCStack management VLAN.

Default The default stacking management VLAN subnet address is 192.168.255.0 with a subnet mask 255.255.255.240 or /28.

Mode Global Configuration

Usage This command is used only in the master and configures the stack management VLAN subnet address.

The management VLAN will be used for high speed communication between stacked units via the inter-stack connection. Although this command enables you to change the IP address command, the subnet mask must always remain as shown.

The VCStack management IP subnet is solely used internally to the stacked devices, and cannot be reached external to the stack. You should only change the VCStack management VLAN subnet address if it causes a conflict within your network.

Note that several separate stacks can use the same default management VLAN subnet address even though their user ports may share the same external network. If the VCStack subnet address is changed, then the configuration for any new units must also be updated before they are inserted into the stack.

If the management VLAN subnet address is changed by this command, you can use the no variant of this command reset it to its default.

Example To set the management VLAN subnet address to 192.168.255.144:

```
awplus# configure terminal
awplus(config)# stack management subnet 192.168.255.144
```

Related Commands stack management vlan

stack management vlan

Use this command to configure the virtual stack management VLAN ID. It can only be entered from the stack master.

Use the no variant of this command to change the virtual stack management VLAN ID back to the default (VLAN ID 4094).

Syntax

```
stack management vlan <2-4094>
no stack management vlan
```

Parameter	Description
<2-4094>	VCStack management VLAN ID. The default is 4094.

Default The default VCStack management VLAN ID is 4094.

Mode Global Configuration

Usage This command is used only in the master and configures the VCStack management VLAN ID.

The management VLAN is used for high speed communication between stacked units via the XEM-STK or the two back panel stacking ports (SwitchBlade® x908 only). This command enables you to change the ID of this VLAN.

The default stacking management VLAN ID is 4094, which is the last configurable VLAN ID in the switch.

The VCStack management VLAN is created and configured automatically so that the VCStack VLAN cannot be used in the stack's VLAN configuration commands (such as `awplus(config-vlan)# vlan <VCS management VLAN ID>`).

The management VLAN should only be changed if the default VCStack VLAN ID needs to be used in the stack's VLAN configuration.

Caution

When the command is entered, the updated management VLAN configuration will take effect once the stack is restarted.

If the management VLAN ID is changed by this command, you can use the no variant of this command to change it back to default value.

Examples To set the management VLAN to 4000, enter the following commands:

```
awplus# configure terminal
awplus(config)# stack management vlan 4000
```

To reset the management VLAN back to the default (4094), enter the following commands:

```
awplus# configure terminal
awplus(config)# no stack management vlan
```

Related Commands stack management subnet

stack priority

Use this command to changes a specific stack member's stack ID and its master-election priority.

Syntax

```
stack <1-8> priority <0-255>
no stack <1-8> priority
```

Parameter	Description
<1-8>	The ID of the stack member that needs to be configured.
`priority`	The stack member's election priority value.
<0-255>	The stack member's new priority value. The lowest value is assigned the highest priority. The default is 128.

Mode Global Configuration

Usage This command is used to change the value of a specific stack member's master-election priority. If the specified member ID is not used by any current stack member, the command will be rejected.

The election criteria selects the stack member with the lowest priority value to become the stack master. Where two stack members both have the same lowest priority value, then the stack member with the lowest MAC address will be elected as master.

Note

Assigning a new priority value will not immediately change the current stack master. In order to force a master re-election after the new priority value is assigned, use reboot stack-member <master's ID> to reboot the current stack master, a new stack master will then be elected based on the new priority values.

Example To change the priority of stack member 4 to be 2, use the commands:

```
awplus# configure terminal
awplus(config)# stack 4 priority 2
```

Validation Command show stack

stack renumber

Use this command to change the ID of a specific stack member.

Syntax `stack <member's-existingID> renumber <member's-newID>`

Parameter	Description
<member's-existingID>	The the stack member ID to be renumbered - also referred to as the "current member ID". Can have a value in the range 1 to 8. We recommend that you use only numbers 1 & 2.
`renumber`	Change the existing stack member ID.
<member's-newID>	The stack member's new ID - also referred to as the new member ID. Can have a value in the range 1 to 8. We recommend that you use only numbers 1 & 2. Note that when operating two member stacks, we advise using stack IDs 1 and 2.

Default Every stack unit will initially try to use stack member ID of 1.

Mode Global Configuration

Usage This command is used to change the ID of a specific stack member - primarily when exchanging stack members. The changes made by this command will not take effect until the switch is rebooted.

Note
This command does not alter any of the stacks's existing configuration, apart from the member-ID specified. For example, if stack member 2 were removed from the stack and a new stack unit is assigned the member 2 stack ID then the interface configuration that existed for the removed stack member 2 will be applied to the new stack member 2.

The *current member ID* must already be assigned to an existing stack member. To avoid duplicating IDs, a warning message will appear if you assign a *new member ID* that is currently assigned to another stack member. However, you can continue to rename the stack member IDs and remove ID duplications. If you do not remove the duplications, then the device with the highest root priority will be allocated this ID. Once you have removed any duplicate IDs, you can reboot the switch to implement your changes.

Note that the configured member-ID is saved immediately on the renumbered member, and so is not reliant on using the copy running-config command for it to take effect

Example To change the stack member ID 2 to be member ID 3, use the commands:

```
awplus# configure terminal
awplus(config)# stack 2 renumber 3
```

Validation Command show stack

stack renumber cascade

This command is used to renumber the members of a stack so that their IDs are ordered sequentially, relative to the member's physical position within the stack.

Caution

Changing the stack numbering will upset the existing stack member configurations such as port settings etc. This command is intended for use when the stack is either initially commissioned, or has undergone a major reconfiguration. In this situation you run the stack renumber command (which will automatically reboot the switch), then configure the stack members to meet the new requirements.

Syntax `stack <1-8> renumber cascade [<1-8>]`

Parameter	Description
<1-8>	The ID of the stack member to start renumbering from.
`renumber`	Change the existing stack member ID.
`cascade`	Renumber the existing stack member ID in cascade order.
<1-8>	The new ID for the first member renumbered.

Default If no member-ID is specified, the member will take the default ID of 1.

Mode Global Configuration

Usage This command is used to renumber the members of a stack so that their member's IDs are ordered sequentially, based on physical order of the XEM-STK connections. This would normally be done either when the stack is initially configured or following a major reconfiguration.

This command is equivalent to pressing and holding the select button on the XEM-STK to renumber the stack members. The renumber will start on the specified stack member. If that member ID is not used by any of the existing stack member, the command will be rejected.

The starting stack member will be renumbered with the new member-ID specified, or the default of member ID of 1. The stack ID of the next physically will be the starting members ID +1, for example member ID 2. This renumbering will continue in cascading order around the stack members.

The changes will take place immediately and reboot all stack members. For this reason a confirmation prompt follows this command entry, asking whether you are sure you want to renumber and reboot the entire stack.

Example

```
awplus(config)# stack 1 renumber cascade
Any existing interface configuration may no longer be valid
Are you sure you want to renumber and reboot the entire stack?
(y/n): y
```

Related Commands show stack
stack renumber

stack resiliencylink

This command configures the resiliency link used by Virtual Chassis Stacking. The interface used may be either an eth0 port or a dedicated VLAN (resiliencylink VLAN) to which switch ports may become members. This VLAN is dedicated to the resiliency link function and must not be the stack management VLAN.

Syntax

```
stack resiliencylink <interface>

no stack resiliencylink
```

Parameters	Description
<interface>	The name of the interface that is connected to the resiliency link. This may be either the eth0 port or the resiliencylink VLAN.

Mode Global Configuration

Usage The resiliency-link is only used when a backup member loses connectivity with the master via the stacking cables. Such a communication loss would occur if:

- a XEM-STK is removed or fails,
- two or more XEM-STK cables are unplugged or fail,
- the stack master itself fails due to a reboot or power failure.

The resiliency-link allows the backup member to determine if the master is still present in the network by the reception of health-check messages sent by the master over the resiliency-link interface.

Reply health-check messages are received if the master is still online, but the stack will now split into two different 'stubs'. The stub containing the existing master will continue operating as normal. The members in the masterless stub will now use a “type stack disabled-master” trigger to run a configuration to form a second temporary stack. This utilizes the remaining stack members' resources without conflicting directly with the master's configuration. If no “type stack disabled-master” trigger was configured on the switches, then the masterless stub members will disable their switch ports.

If no health-check messages are received, then the master is assumed to be completely offline, and so the other stack members can safely take over the master's configuration.

Caution

The purpose of the resiliency link is to enable the stack members (particularly the backup master) to check the status of the master under fault conditions. If the resiliency link is not configured, and the master loses communication with its other stack members, then Virtual Chassis Stacking will assume the master is NOT present in the network, which could cause network conflicts if the master is still on line. Note that this is a change to the stacking of releases prior to version 5.3.1.

Example To set the resiliency link to be `eth0`:

```
awplus# configure terminal
awplus(config)# stack resiliencylink eth0
```

To set the resiliency link to be VLAN 4093.

First use the stack resiliencylink command to create the resiliency `vlan 4093`

```
awplus# configure terminal
awplus(config)# stack resiliencylink vlan4093
```

Next use the switchport resiliencylink command to assign the resiliencylink vlan to the interface port, in this case `port1.0.1`.

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# switchport resiliencylink
```

switchport resiliencylink

stack software-auto-synchronize

This command is used only on the stack master and enables the software version auto-synchronization feature either on a specified stack member or all stack members and candidates. A stack candidate is a switch that is about to join a stack.

Use the no variant of this command to turn the software version auto synchronization feature off.

Syntax

```
stack {all|<1-8>} software-auto-synchronize
no stack {all|<1-8>} software-auto-synchronize
```

Parameter	Description
`all`	All stack members.
<1-8>	The ID of a stack member.

Default All the stack members have the stack software-auto-synchronize feature enabled by default.

Mode Global Configuration

Usage This command is used to enable the software version auto-synchronization feature for either a specific stack member or all stack members and candidates.

Note that if a stack candidate attempts to join a stack, but is running a software release that is different to the other stack members, then the software version auto-synchronization feature will copy the master's software release onto the new candidate. If the software version auto-synchronization feature is not enabled, then the candidate will be rejected from the stack.

Note that the software version auto-synchronization feature may also result in the stack candidate downgrading its software release if the master is running an older software version.

Examples To turn on the software-auto-synchronize feature on stack member 2, which was previously turned off, use the following commands:

```
awplus# configure terminal
awplus(config# stack 2 software-auto-synchronize
```

To turn on the software-auto-synchronize feature for all stack members, which were previously turned off, use the following commands:

```
awplus# configure terminal
awplus(config)# stack all software-auto-synchronize
```

Validation Command show stack

stack virtual-chassis-id

This command specifies the VCStack virtual chassis ID. The ID selected will determine which virtual MAC address the stack will use. The MAC address assigned to a stack must be unique within its network.

Note The command will not take effect until the switch has been rebooted.

Syntax

```
stack virtual-chassis-id <id>
```

Parameter	Description
<id>	The value of the ID - enter a number in the range 0 to 4095.

Mode Global Configuration

Usage The virtual-chassis-id entered will form the last 12 bits of a pre selected MAC prefix component; that is, `0000.cd37.0xxx`. If you enable the VCStack virtual MAC address feature (by using the stack virtual-mac command) without using the stack virtual-chassis-id command to select the virtual-chassis-id, then the stack will select a virtual-chassis-id from a number within the assigned range.

Example To set the stack virtual-chassis-id to 63 use the commands

```
awplus# configure terminal
awplus(config)# stack virtual-chassis-id 63
```

This will result in a virtual MAC address of: `0000.cd37.003f`.

Related Commands

show running-config

stack virtual-mac

stack virtual-mac

This command enables the VCStack virtual MAC address feature. For more information on this topic refer to "Fixed or Virtual MAC Addressing" on page 102.13. With this command set, the value applied for the virtual MAC address is determined by the setting of the command stack virtual-chassis-id command on page 103.37.

Note This command will not take effect until the switch has been rebooted.

Syntax

```
stack virtual-mac
no stack virtual mac
```

Mode Global Configuration

Example

```
awplus# configure terminal
awplus(config)# stack virtual mac
```

Related Commands

show running-config

stack virtual-chassis-id

switch provision

This command enables you provide the configuration for a new VCStack member switch prior to physically connecting it to the stack. To run this command, the stack position must be vacant. The selected hardware type must be compatible existing stack hardware.

Use the no variant of this command to remove an existing switch provision.

Syntax

```
switch <1-8> {provision|reprovision}{x900-12|x900-24|x908}
no switch <1-8> provision
```

Parameter	Description
<1-8>	The stack member switch position to be provisioned.
`provision`	Provides settings within the stack configuration ready for a specific switch type to become a stack member.
`reprovision`	Reconfigure an existing provision configuration.
`x900-12`	Provision an x900-12switch.
`x900-24`	Provision an x900-24 switch.
`x908`	Provision an x908 switch.

Mode Global Configuration

Examples x900: To reprovision the switch to be an x900-12 switch as stack member 2, use the following commands:

```
awplus# configure terminal
awplus(config)# switch 2 reprovision x900-12
```

x900: To remove the provision of the x900-12 switch as stack member 2, use the following commands:

```
awplus# configure terminal
awplus(config)# no switch 2 provision
```

Related Commands show provisioning (stack-member)

switchport resiliencylink

This command configures the switch port to be a member of the stack resiliency link VLAN. Note that this switchport will only be used for stack resiliency-link traffic and will not perform any other function, or carry any other traffic.

The no variant of this command removes the switchport from the resiliency link VLAN.

Syntax

```
switchport resiliencylink
no switchport resiliencylink
```

Mode Global Configuration

Examples To set the resiliency link to be VLAN 4093.

First use the stack resiliencylink command to create the resiliency `vlan4093`

```
awplus# configure terminal
awplus(config)# stack resiliencylink vlan4093
```

Next use the switchport resiliencylink command to assign the resiliencylink vlan to the 31 port, in this case `port1.0.1`.

```
awplus# configure terminal
awplus(config)# interface port1.0.1
awplus(config-if)# switchport resiliencylink
```

Appendix B: Changes in Version 5.4.2-0.1

This appendix lists the changes made in Version 5.4.2.

- New or Changed Features: (Table B-1 on page B.1)
- New or Changed Commands: (Table B-2 on page B.4)
- New or Changed SNMP MIBs: (Table B-3 on page B.36)

Clicking on a topic in the Feature column will take you to the appropriate section of the manual.

Table B-1: New or Change Features

Feature	Status	Chapter / Section	Description
Extended VRF-Lite Support Environments	Modified	VRF-Lite Introduction and Configuration	VRF-Lite now also supports the following features: VLAN Tagging with Multiple VRF-Lite Instances, VCStack (Virtual Chassis Stacking), “route limits,” and user-configurable static and dynamic routing resource limits that can be applied on a per-VRF basis.
The AlliedWare Plus TACACS+ Implementation	Modified	TACACS+ Introduction and Configuration	The AlliedWare Plus™ TACACS+ implementation now supports TACACS+ accounting. In addition, support for TACACS+ enable password authentication has been added.
Trouble-shoot fiber and pluggable issues	New	Getting Started	You can now trouble-shoot fiber cable and pluggable issues with diagnostic information about installed XFP and SFP pluggable transceivers, where SFPs are installed in the switch that support DDM (Digital Diagnostic Monitoring) functionality and XFPs are installed in the switch that support DOM (Digital Optical Monitoring) functionality.
The Autoboot Feature	New	Creating and Managing Files	The Autoboot feature enables the device to automatically load a specific release file and/or configuration file from external media, such as an SD card, into Flash memory. The Autoboot feature is disabled by default.
PIM-SSM	New	PIM-SM Introduction and Configuration	Protocol Independent Multicast - Source Specific Multicast (PIM-SSM) is supported in this software version.
Introduction	New	EPSR Introduction and Configuration	Where interlinked EPSR rings share a common segment and common data VLANs, a break in the common segment can result in a path loop existing around the rings. Loop Protection avoids this problem by applying priorities to the master node ring ports. These priorities modify the blocking behavior of these ports if a break occurs in the shared segment.

Table B-1: New or Change Features(cont.)

Feature	Status	Chapter / Section	Description
IPv6 enhancements	New	IPv6 Introduction NTP Introduction and Configuration Dynamic Host Configuration Protocol (DHCP) Introduction Internet Protocol (IP) Addressing and Protocols	IPv6 on the switches now supports: ■ IPv6 RA Guard Because an entire IPv6 network configuration can be modified by what is contained in Router Advertisements, the network is vulnerable to rogue messages that are generated either through misconfiguration or due to a malicious attack. RA Guard (RFC6105) defends against these vulnerabilities by blocking RAs and redirects received from the untrusted hosts connected to untrusted ports. For more information, see the IPv6 Introduction chapter in the Software Reference. ■ NTP over IPv6 In addition to existing support for NTP via IPv4 addresses, NTP on the switch is now able to synchronize time via IPv6. NTP peer and NTP server addresses can now be specified in the form of IPv6 addresses. For more information, see the NTP Introduction and Configuration chapter in the Software Reference. ■ DHCP Relay over IPv6 While stateless address autoconfiguration is the IPv6 way of automatically configuring hosts' network information, it is not fully supported by some vendors, so Dynamic Host Configuration Protocol is still commonly used. Where the DHCPv6 server does not reside on the same IP subnet as its clients, a relay agent can act as an intermediate device between the two subnets. Alliedware Plus DHCP relay now supports IPv6 addresses, in addition to existing support for IPv4 addresses. For more information, see the Dynamic Host Configuration Protocol (DHCP) Introduction chapter in the Software Reference. ■ DNS Relay over IPv6 In addition to existing support for DNS relay via IPv4, you can now access a domain name server via an IPv6 network. For more information, see the Internet Protocol (IP) Addressing and Protocols chapter in the Software Reference.

Table B-1: New or Change Features(cont.)

Feature	Status	Chapter / Section	Description
Privilege level enhancements	Modified	User Access Commands	AlliedWare Plus now supports 15 privilege levels, divided into 3 groups: ■ levels 1-6 provide access to most show commands, in User Exec mode ■ levels 7-14 provide access to some more show commands, in Privileged Exec mode ■ level 15 provides access to some additional show commands and all configuration commands, in Privileged Exec mode Network administrators can now control user access to each privilege level by configuring separate enable passwords for each privilege level, and configuring each user's initial privilege level (for locally configured users). Users can move from their initial privilege level to a higher level by entering the enable command, specifying a privilege level, and entering that level's password. These enhancements mean that network administrators can manage user access rights to network devices more effectively than was previously possible. The following command changes are introduced to support these enhancements: ■ For the username command, the meaning of the level parameter has changed. This is now the maximum privilege level that you can access without having to enter an enable password. ■ The enable password and enable secret commands now store up to 15 different passwords. You can enter these passwords to access privilege levels greater than their configured privilege level. You can not access levels above your configured privilege level unless an enable password has been configured for that level. ■ The enable commands now take an optional level parameter that specifies which level you want to access. ■ A new command enables AAA authentication to determine the privilege level that you can access for passwords authenticated locally. See the aaa authentication enable default local command in the chapter, AAA Commands. ■ Many show commands that were previously available at privilege level 7 are now available at privilege level 1 or 15 instead. ■ As before, you can display your current privilege level. See the show privilege command in the chapter, User Access Commands chapter.

Table B-1: New or Change Features(cont.)

Feature	Status	Chapter / Section	Description
Superloop Protection	New	EPSR Introduction and Configuration	Where interlinked EPSR rings share a common segment and data VLANs, a break in the common segment can result in a path loop around the rings. Superloop Protection avoids this problem by modify the blocking behavior of these ports when this condition occurs.

Table B-2: New or Changed Commands

Feature		Status	Chapter / Section	Description
enable (Privileged Exec mode)	Command	Modified	CLI Navigation Commands	You can now optionally set the privilege level for a session with this command, as well as entering the Privileged Exec mode. If the privilege level is omitted then only users with the maximum privilege level can access Privileged Exec mode without providing the password as specified by the enable password or enable secret commands. If no password is specified then only users with the maximum privilege level set with the username command can assess Privileged Exec mode.
show history	Command	Modified	CLI Navigation Commands	You can now access this command from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
enable password	Command	Modified	User Access Commands	You can now set a local password to control access to various privilege levels with this command. Note that the enable secret command is an alias for the enable password command, and the no enable secret command is an alias for the no enable password command.
enable secret	Command	Modified	User Access Commands	You can now set a local password to control access to various privilege levels with this command. Note that the enable secret command is an alias for the enable password command, and the no enable secret command is an alias for the no enable password command. Note that if this command is entered then enable password is shown in the configuration.
flowcontrol hardware (asyn/ console)	Command	New	User Access Commands	With this command you can now enable and disable RTS/CTS (Ready To Send/Clear To Send) hardware flow control on a terminal console line (asyn port) between the DTE (Data Terminal Equipment) and the DCE (Data Communications Equipment).
show telnet	Command	Modified	User Access Commands	You can now access this command from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
terminal resize	Command	New	User Access Commands	Use this command to automatically adjust the number of rows of output on the console that the device will display before pausing, to the number of rows configured on the user's terminal.
autoboot enable	Command	New	File Management Commands	Use this command to enable the device to restore a release file and/or a configuration file from external media.
create autoboot	Command	New	File Management Commands	Use this command to create an autoboot.txt file on external media.
show autoboot	Command	New	File Management Commands	Use this command to display the Autoboot configuration and status.
show boot	Command	Modified	File Management Commands	This command now displays the status of the Autoboot feature.
show running-config	Command	Modified	File Management Commands	This command is available from the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show running-config interface	Command	Modified	File Management Commands	This command is available from the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show running-config lldp	Command	Modified	File Management Commands	This command is available from the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
max-fib-routes	Command	Modified	System Configuration and Monitoring Commands	This command now enables you to control the maximum number of FIB routes configured. It operates by providing parameters that enable you to configure preset maximums and warning message thresholds.
show cpu	Command	Modified	System Configuration and Monitoring Commands	You can now separately display CPU processes for individual stack members.
show cpu history	Command	Modified	System Configuration and Monitoring Commands	You can also display CPU process history for individual stack members.
show debugging	Command	Modified	System Configuration and Monitoring Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show diagnostic monitor pcsping	Command	Modified	System Configuration and Monitoring Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show memory	Command	Modified	System Configuration and Monitoring Commands	You can now additionally display CPU memory for individual stack members.

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show memory history	Command	Modified	System Configuration and Monitoring Commands	You can now additionally display CPU memory history for individual stack members.
show process	Command	Modified	System Configuration and Monitoring Commands	You can now run this command for individual stack members.
show router-id	Command	Modified	System Configuration and Monitoring Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show system pluggable	Command	Modified	System Configuration and Monitoring Commands	Support for SFP DDM (Digital Diagnostics Monitoring) and XFP DOM (Digital Optical Monitoring) has been added. You can now select all pluggables on the switch, or a single pluggable on the switch, or a range of pluggables on the switch with the optional <port-list> placeholder.
show system pluggable detail	Command	Modified	System Configuration and Monitoring Commands	Support for SFP DDM (Digital Diagnostics Monitoring) and XFP DOM (Digital Optical Monitoring) diagnostics has been added. You can now select eitehr a single, or all pluggables on the switch, or a range of pluggables on the switch with the optional <port-list> placeholder.
show system pluggable diagnostics	Command	New	System Configuration and Monitoring Commands	Support for SFP DDM (Digital Diagnostics Monitoring) and XFP DOM (Digital Optical Monitoring) diagnostics has been added. This command displays diagnostic information about the pluggable transceivers that are currently installed in your switch.
show counter log	Command	Modified	Logging Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show exception log	Command	Modified	Logging Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show log	Command	Modified	Logging Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration command mode prompt (awplus(config)#).
show log config	Command	Modified	Logging Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration command mode prompt (awplus(config)#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show log permanent	Command	Modified	Logging Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration command mode prompt (awplus(config)#).
clear mac address-table dynamic	Command	Modified	Switching Commands	Use this command to clear the filtering database of all entries learned for a selected MAC address, an MSTP instance, a switch port interface or a VLAN interface. This command now includes an optional MSTI instance for the switch port.
platform enhancedmode (deprecated)	Command	Deprecated	Switching Commands	This command has been replaced by the new platform silicon-profile command.
platform silicon-profile	Command	New	Switching Commands	This command replaces the deprecated command platform enhanced-mode. A new silicon profile option for a SwitchBlade x908 with all XEM-2XP, XEM-2XT, and XEM-2XS XEMs installed increases hardware table sizes.
show debugging loopprot	Command	Modified	Switching Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging platform packet	Command	Modified	Switching Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show flowcontrol interface	Command	Modified	Switching Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show loop-protection	Command	Modified	Switching Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mirror	Command	Modified	Switching Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mirror interface	Command	Modified	Switching Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration command mode prompt (awplus(config-if)#).
show provisioning (xem-bay)	Command	Modified	Switching Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show storm-control	Command	Modified	Switching Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show vlan	Command	Modified	VLAN Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show vlan classifier group	Command	Modified	VLAN Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show vlan classifier group interface	Command	Modified	VLAN Commands	Use this command to display information about all switch port interfaces or a single switch port interface for all configured VLAN classifier groups.
show vlan classifier interface group	Command	Modified	VLAN Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show vlan classifier rule	Command	Modified	VLAN Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show vlan private-vlan	Command	Modified	VLAN Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
vlan classifier activate	Command	Modified	VLAN Commands	This command can now optionally associate a VLAN identifier with a VLAN classifier group. This command primarily associates and removes VLAN classifier groups with switch port interfaces in Interface Configuration.
vlan classifier rule ipv4	Command	Modified	VLAN Commands	You can now set up to twelve IPv4 subnet-based VLAN classifier rules. If you attempt to set more than twelve rules an error message is displayed.
vlan classifier rule proto	Command	Modified	VLAN Commands	You can now set up to twelve protocol type-based VLAN classifier rules. If you attempt to set more than twelve rules an error message is displayed.
clear spanning-tree statistics	Command	Modified	Spanning Tree Commands	You can now optionally specify an MSTI (Multiple Spanning Tree Instance) instance to clear MSTP BPDU statistics with this revised command.
instance priority (MSTP)	Command	Modified	Spanning Tree Commands	You can now specify <1-63> MSTIs for a switch port with this revised command to set the priority for the switch to become the root bridge for the specified MSTI.

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
instance vlan (MSTP)	Command	Modified	Spanning Tree Commands	The range of MSTIs for a switch port has increased from <1-15> to <1-63>. Use this command to create an MST Instance (MSTI), and associate the specified VLANs with it. An MSTI is a spanning tree instance that exists within an MST region (MSTR). An MSTR can contain up to 63 MSTIs.
show debugging mstp	Command	Modified	Spanning Tree Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show spanning-tree	Command	Modified	Spanning Tree Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration mode prompt (awplus(config-if)#).
show spanning-tree brief	Command	Modified	Spanning Tree Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration mode prompt (awplus(config-if)#).
show spanning-tree mst	Command	Modified	Spanning Tree Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration mode prompt (awplus(config-if)#).
show spanning-tree mst config	Command	Modified	Spanning Tree Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration mode prompt (awplus(config-if)#).
show spanning-tree mst detail	Command	Modified	Spanning Tree Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration mode prompt (awplus(config-if)#).
show spanning-tree mst detail interface	Command	Modified	Spanning Tree Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration mode prompt (awplus(config-if)#).
show spanning-tree mst instance	Command	Modified	Spanning Tree Commands	The range of MSTI instances for a switch port has increased from <1-15> to <1-63>. This command is now available from the User Exec command mode prompt (awplus>), Privileged Exec command mode prompt (awplus#) and Interface Configuration mode prompt (awplus(config-if)#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show spanning-tree mst instance interface	Command	Modified	Spanning Tree Commands	The range of MST instances for a switch port increased from <1-15> to <1-63>. This command is now also available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration mode prompt (awplus(config-if)#)
show spanning-tree mst interface	Command	Modified	Spanning Tree Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration mode prompt (awplus(config-if)#).
show spanning-tree mst detail interface	Command	Modified	Spanning Tree Commands	This command is now available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Interface Configuration mode prompt (awplus(config-if)#).
show spanning-tree statistics	Command	New	Spanning Tree Commands	This command displays BPDU (Bridge Protocol Data Unit) statistics for all spanning-tree instances, and all switch ports associated with all spanning-tree instances.
show spanning-tree statistics instance	Command	Modified	Spanning Tree Commands	The range of MSTI instances for a switch port increased from <1-15> to <1-63>. This command displays BPDU (Bridge Protocol Data Unit) statistics for the specified MST instance, and all switch ports associated with that MST instance.
show spanning-tree statistics instance interface	Command	Modified	Spanning Tree Commands	The range of MSTI instances for a switch port has increased from <1-15> to <1-63>. This command displays BPDU (Bridge Protocol Data Unit) statistics for the specified MST (Multiple Spanning Tree) instance and the specified switch port associated with that MST instance.
show spanning-tree statistics interface	Command	Modified	Spanning Tree Commands	The range of MSTI instances for a switch port increased from <1-15> to <1-63>. This command displays BPDU (Bridge Protocol Data Unit) statistics for the specified switch port, and all MST instances associated with that switch port.
show spanning-tree vlan range-index	Command	New	Spanning Tree Commands	Use this new command to display information about MST (Multiple Spanning Tree) instances and the VLANs associated with them including the VLAN range-index value for the switch.
spanning-tree mst instance	Command	Modified	Spanning Tree Commands	The range of MSTIs for a switch port has increased from <1-15> to <1-63>. Use this command to assign a Multiple Spanning Tree instance (MSTI) to a switch port or channel group.

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
spanning-tree mst instance path-cost	Command	Modified	Spanning Tree Commands	The range of MSTI instances for a switch port has increased from <1-15> to <1-63>. Use this command to set the cost of a path associated with a port, for the specified MSTI (Multiple Spanning Tree Instance) identifier.
spanning-tree mst instance priority	Command	Modified	Spanning Tree Commands	The range of MSTI instances for a switch port has increased from <1-15> to <1-63>. Use this command to set the port priority for an MST instance (MSTI).
spanning-tree mst instance restricted-role	Command	New	Spanning Tree Commands	This command enables the restricted role for an MSTI on a switch port. The “no”’ variant of this command disables the restricted role for an MSTI on a switch port allowing the switch port to become the root port in a spanning tree topology.
spanning-tree mst instance restricted-tcn	Command	New	Spanning Tree Commands	Use this new command in Interface Configuration mode to set the restricted TCN (Topology Change Notification) value to TRUE for the specified MSTI . Use the no variant of this command to reset the restricted TCN for the specified MSTI to the default value of FALSE.
show debugging lacp	Command	Modified	Link Aggregation Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show diagnostic channel-group	Command	Modified	Link Aggregation Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show etherchannel detail	Command	Modified	Link Aggregation Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show etherchannel summary	Command	Modified	Link Aggregation Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show lacp-counter	Command	Modified	Link Aggregation Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show lacp sys-id	Command	Modified	Link Aggregation Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show port etherchannel	Command	Modified	Link Aggregation Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show debugging gvrp	Command	Modified	GVRP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show gvrp configuration	Command	Modified	GVRP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show gvrp machine	Command	Modified	GVRP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show gvrp statistics	Command	Modified	GVRP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show gvrp timer	Command	Modified	GVRP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
arp opportunistic-nd	Command	New	IP Addressing and Protocol Commands	This command enables opportunistic neighbor discovery for the global ARP cache, or a specified named VRF instance. The no variant of this command disables opportunistic neighbor discovery Opportunistic neighbor discovery changes the behavior for unsolicited ARP packet forwarding on the switch.
ip name-server	Command	Modified	IP Addressing and Protocol Commands	This command now adds the IPv6 address of a DNS server to the device's list of servers. The DNS client on your device sends DNS queries to devices on this list when trying to resolve a DNS hostname.
show debugging ip dns forwarding	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging ip packet	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show hosts	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging ip dns forwarding	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ip dns forwarding cache	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip domain-list	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip domain-name	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip forwarding	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip interface	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip interface vrf	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip irdp	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip irdp interface	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip name-server	Command	Modified	IP Addressing and Protocol Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
ipv6 address	Command	Modified	IPv6 Commands	You can now use this command to set the IPv6 address of a VLAN interface and enable IPv6 with an optional eui64 parameter to apply the MAC address of the interface. Note that the MAC address of the default VLAN is applied if the interface does not have a MAC address of its own when specifying the eui64 parameter.
ipv6 address autoconfig	Command	New	IPv6 Commands	Use this new command to enable IPv6 stateless address autoconfiguration (SLAAC) on an interface This configures an IPv6 address on an interface derived from the MAC address on the interface.

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
ipv6 enable	Command	Modified	IPv6 Commands	This revised command now enables IPv6 with a IPv6 link-local address not with an IPv6 global address. Use this command to enable IPv6 on an interface without an IPv6 global address set for the interface.
ipv6 nd current-hoplimit	Command	New	IPv6 Commands	Use this new command to specify the advertised current hop limit used between IPv6 Routers.
ipv6 nd minimum-ra-interval	Command	New	IPv6 Commands	Use this new command in Interface Configuration mode to set a minimum Router Advertisement (RA) interval for a VLAN interface. Use the no variant of this command in Interface Configuration mode to remove the minimum RA interval for a VLAN interface.
ipv6 nd prefix	Command	Modified	IPv6 Commands	The no-autoconfig and offlink parameters have been added to this command and its “no” varient. Use this command to specify the IPv6 prefix information that is advertised by the router advertisement for IPv6 address auto-configuration. Use the no parameter with this command to reset the IPv6 prefix.
ipv6 nd ra-interval	Command	Modified	IPv6 Commands	The Router Advertisements (RA) interval range has changed from <3-1800> seconds to <4-1800> seconds. Use this revised command to specify the interval between IPv6 RA transmissions. The no variant of this command resets the IPv6 RA interval to the default of 600 seconds.
ipv6 nd retransmission-time	Command	New	IPv6 Commands	Use this new command to specify the advertised retransmission interval for Neighbor Solicitation in milliseconds between IPv6 Routers.
ipv6 opportunistic-nd	Command	New	IPv6 Commands	Use this new command to enable opportunistic neighbor discovery for the global IPv6 ARP cache. Use the no variant of this command to disable opportunistic neighbor discovery for the global IPv6 ARP cache. Opportunistic neighbor discovery changes the behavior for unsolicited ARP packet forwarding on the switch.
show ipv6 forwarding	Command	Modified	IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 interface brief	Command	Modified	IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 neighbors	Command	Modified	IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ipv6 route	Command	Modified	IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 route summary	Command	Modified	IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip route	Command	Modified	Routing Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip route database	Command	Modified	Routing Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip route summary	Command	Modified	Routing Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging rip	Command	Modified	RIP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip protocols rip	Command	Modified	RIP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip rip	Command	Modified	RIP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#)
show ip rip database	Command	Modified	RIP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

show ip rip vrf database	Command	Modified	RIP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip rip vrf interface	Command	Modified	RIP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show debugging ipv6 rip	Command	Modified	RIPng Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 protocols rip	Command	Modified	RIPng Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 rip	Command	Modified	RIPng Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 rip database	Command	Modified	RIPng Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 rip interface	Command	Modified	RIPng Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging ospf	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf border-routers	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf database	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf database asbr-summary	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf database external	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf database network	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ip ospf database nssa-external	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf database opaque-area	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf database opaque-as	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf database opaque-link	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf database router	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf database summary	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf interface	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf neighbor	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf route	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip ospf virtual-links	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip protocols ospf	Command	Modified	OSPF Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging ipv6 ospf	Command	Modified	OSPFv3 for IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ipv6 ospf	Command	Modified	OSPFv3 for IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 ospf database	Command	Modified	OSPFv3 for IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 ospf database external	Command	Modified	OSPFv3 for IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 ospf database network	Command	Modified	OSPFv3 for IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 ospf database router	Command	Modified	OSPFv3 for IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 ospf interface	Command	Modified	OSPFv3 for IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 ospf neighbor	Command	Modified	OSPFv3 for IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 ospf route	Command	Modified	OSPFv3 for IPv6 Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
debug bgp	Command	Modified	BGP Commands	Use this command to turn on one or more BGP debug options. This command now has the option to debug for BGP NHT (Next Hop Tracking). You can also now issue this command from Privileged Exec and Global Configuration command modes at the awplus# and awplus(config)# prompts respectively.
show bgp nexthop-tracking	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show bgp nexthop-tree-details	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show bgp memory maxallocation	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging bgp	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp attribute-info	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp cidr-only	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp community	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp community-info	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp community-list	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp dampening	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp filter-list	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp inconsistent-as	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp longer-prefixes	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ip bgp neighbors	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp neighbors connection-retrytime	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp neighbors hold-time	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp neighbors keepalive	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp neighbors keepalive-interval	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp neighbors notification	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp neighbors open	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp neighbors rcvd-msgs	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp neighbors sent-msgs	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp neighbors update	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp paths	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp prefix-list	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ip bgp quote-regexp	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp regexp	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp route-map	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp scan	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp summary	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp view	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp view neighbors	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip bgp view summary	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip community-list	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip extcommunity-list	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip protocols bgp	Command	Modified	BGP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
undebug bgp	Command	Modified	BGP Commands	Use this command to disable BGP debugging functions. This command now has the option to disable BGP NHT (Next Hop Tracking) debugging. You can also now issue this command from Privileged Exec and Global Configuration command modes at the awplus# and awplus(config)# prompts respectively.
show route-map	Command	Modified	Route Map Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
max-fib-routes (VRF)	Command	Modified	VRF-Lite Commands	This command now enables you to control the maximum number of FIB routes configured for a VRF Instance. It operates by providing parameters that enable you to configure preset maximums and warning message thresholds.
max-static-routes	Command	Modified	VRF-Lite Commands	This command now enables you to set the maximum number of static routes (excluding FIB—Forwarding Information Base routes) for VRF Instances.
show ip vrf	Command	Modified	VRF-Lite Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip vrf detail	Command	Modified	VRF-Lite Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip vrf	Command	Modified	VRF-Lite Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
ip multicast route	Command	New	Multicast Introduction and Commands	Use this command to add a static multicast route for a specific mulitcast source and group address to the multicast Routing Information Base (RIB).
ip multicast wrong-vif-suppression	Command	New	Multicast Introduction and Commands	Use this command to prevent unwanted multicast packets received on an unexpected VLAN being trapped to the CPU.
show ip mroute	Command	Modified	Multicast Introduction and Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip mvif	Command	Modified	Multicast Introduction and Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ip rpf	Command	Modified	Multicast Introduction and Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
ip igmp ssm	Command	New	IGMP and IGMP Snooping Commands	Use this command to define a non-default Source Specific Multicast (SSM) range of IP multicast addresses in IGMP. Incoming IGMPv1 and IGMPv2 join requests are ignored if the multicast IP address is in the SSM range and no SSM mapping is configured for these addresses. By default, the SSM range is 232/8.
ip igmp ssm-map enable	Command	New	IGMP and IGMP Snooping Commands	Use this command to enable Source Specific Multicast (SSM) mapping on the device.
ip igmp ssm-map static	Command	New	IGMP and IGMP Snooping Commands	Use this command to specify the static mode of defining Source Specific Multicast (SSM) mapping. SSM statically assigns sources to IGMPv1 and IGMPv2 groups to translate such (*,G) groups' memberships to (S,G) memberships for use with PIM-SSM.
ip igmp startup-query-count	Command	New	IGMP and IGMP Snooping Commands	Use this command to configure the IGMP startup query count on a VLAN interface in Interface Configuration mode. The IGMP startup query count is the number of general query messages sent at startup. The default IGMP startup query count is 2.
ip igmp startup-query-interval	Command	New	IGMP and IGMP Snooping Commands	Use this command to configure the IGMP startup query interval for a VLAN interface in Interface Configuration mode. The IGMP startup query interval is the amount of time in seconds between successive IGMP General Query messages sent by a querier during startup. The default IGMP startup query interval is one quarter of the IGMP query interval value.
show debugging igmp	Command	Modified	IGMP and IGMP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip igmp groups	Command	Modified	IGMP and IGMP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip igmp interface	Command	Modified	IGMP and IGMP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip igmp proxy	Command	New	IGMP and IGMP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ip igmp snooping mrouter	Command	Modified	IGMP and IGMP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip igmp snooping routermode	Command	Modified	IGMP and IGMP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip igmp snooping statistics	Command	Modified	IGMP and IGMP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
ip pim ssm	Command	New	PIM-SM Commands	Use this command to define the Source Specific Multicast (SSM) range of IP multicast addresses.
show debugging pim sparse-mode	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim sparse-mode bsr-router	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim sparse-mode interface	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim sparse-mode interface detail	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim sparse-mode mroute	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim sparse-mode mroute detail	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim sparse-mode neighbor	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim sparse-mode nexthop	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ip pim sparse-mode rp-hash	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim sparse-mode rp mapping	Command	Modified	PIM-SM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging pim dense-mode	Command	Modified	PIM-DM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim dense-mode interface	Command	Modified	PIM-DM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim dense-mode interface detail	Command	Modified	PIM-DM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim dense-mode mroute	Command	Modified	PIM-DM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim dense-mode neighbor	Command	Modified	PIM-DM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim dense-mode neighbor detail	Command	Modified	PIM-DM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip pim dense-mode nexthop	Command	Modified	PIM-DM Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 mld groups	Command	Modified	MLD Snooping Introduction and Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 mld interface	Command	Modified	MLD Snooping Introduction and Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ipv6 mld snooping mrouter	Command	Modified	MLD Snooping Introduction and Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ipv6 mld snooping statistics	Command	Modified	MLD Snooping Introduction and Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
commit (IPv4)	Command	New	IPv4 Hardware Access Control List (ACL) Commands	Use this command to commit the ACL filter configuration to hardware immediately without exiting Hardware ACL Configuration mode.
show access-group	Command	Modified	IPv4 Hardware Access Control List (ACL) Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show access-list (IPv4 Hardware ACLs)	Command	Modified	IPv4 Hardware Access Control List (ACL) Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show access-list (IPv4 Software ACLs)	Command	Modified	IPv4 Software Access Control List (ACL) Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip access-list	Command	Modified	IPv4 Software Access Control List (ACL) Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip prefix-list	Command	Modified	IPv4 Software Access Control List (ACL) Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
commit (IPv6)	Command	New	IPv6 Hardware Access Control List (ACL) Commands	Use this command to commit the ACL filter configuration to hardware immediately without exiting Hardware ACL Configuration mode.
show ipv6 access-list (IPv6 Hardware ACLs)	Command	Modified	IPv6 Hardware Access Control List (ACL) Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
ipv6 access-list extended proto	Command	New	IPv6 Software Access Control List (ACL) Commands	Use this command when configuring an IPv6 extended access-list for filtering frames that permit or deny packets with a specific value based on the IP protocol number specified. The no variant of this command removes a specified IPv6 extended access-list with an IP protocol number.
show ipv6 access-list (IPv6 Software ACLs)	Command	Modified	IPv6 Software Access Control List (ACL) Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
police-aggregate	Command	Modified	QoS Commands	Use this command to apply a previously created aggregate-policer to the class-map. The command syntax has changed from police aggregate to police-aggregate. Note that a console message is displayed indicating the previous command syntax police aggregate is deprecated and is available as an alias to the police-aggregate keyword.
show class-map	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos aggregate-policer	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos fabric-queue	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos interface	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos interface policer-counters	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos interface queue-counters	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos interface storm-status	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos maps cos-queue	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos fabric-queue	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos maps policed-dscp	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show mls qos maps premark-dscp	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show mls qos queue-set	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show policy-map	Command	Modified	QoS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging dot1x	Command	Modified	802.1X Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
aaa accounting commands	Command	New	AAA Commands	With this command you can configure and enable TACACS+ command accounting.
aaa accounting login	Command	Modified	AAA Commands	With this command you can now configure TACACS+ accounting for login shell sessions.
aaa accounting update	Command	Modified	AAA Commands	This command now enables periodic accounting reporting to a TACACS+ accounting server.
aaa authentication enable default group tacacs+	Command	New	AAA Commands	This command enables AAA authentication to determine the privilege level a user can access for passwords authenticated against the TACACS+ server.
aaa authentication enable default local	Command	New	AAA Commands	This command enables AAA authentication to determine the privilege level a user can access for passwords authenticated locally.
show debugging aaa	Command	Modified	AAA Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging radius	Command	Modified	RADIUS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show radius	Command	Modified	RADIUS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show radius statistics	Command	Modified	RADIUS Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show tacacs+	Command	Modified	TACACS+ Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
domain-style	Command	New	Local RADIUS Server Commands	Use this command to enable a specified domain style on the local RADIUS server. The local RADIUS server decodes the domain portion of a username login string when this command is enabled.
show crypto pki certificates	Command	Modified	Local RADIUS Server Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show crypto pki certificates local-radius-all-users	Command	Modified	Local RADIUS Server Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show crypto pki certificates user	Command	Modified	Local RADIUS Server Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show crypto pki trustpoints	Command	Modified	Local RADIUS Server Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show radius local-server group	Command	Modified	Local RADIUS Server Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show radius local-server nas	Command	Modified	Local RADIUS Server Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration mode prompt (awplus(config)#).
show radius local-server statistics	Command	Modified	Local RADIUS Server Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show radius local-server user	Command	Modified	Local RADIUS Server Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#), and the Global Configuration mode prompt (awplus(config)#).
show crypto key hostkey	Command	Modified	Secure Shell (SSH) Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show crypto key pubkey-chain knownhosts	Command	Modified	Secure Shell (SSH) Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show crypto key pubkey-chain userkey	Command	Modified	Secure Shell (SSH) Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show crypto key userkey	Command	Modified	Secure Shell (SSH) Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show running-config ssh	Command	Modified	Secure Shell (SSH) Commands	This command is available from the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show ssh	Command	Modified	Secure Shell (SSH) Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show ssh client	Command	Modified	Secure Shell (SSH) Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show ssh server	Command	Modified	Secure Shell (SSH) Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show ssh server allow-users	Command	Modified	Secure Shell (SSH) Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show ssh server deny-users	Command	Modified	Secure Shell (SSH) Commands	This command is available from the User Exec command mode prompt (awplus>), the Privileged Exec command mode prompt (awplus#) and the Global Configuration prompt (awplus(config)#).
show debugging arp security	Command	Modified	DHCP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

show ip dhcp snooping binding	Command	Modified	DHCP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip dhcp snooping interface	Command	Modified	DHCP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip dhcp snooping statistics	Command	Modified	DHCP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip source binding	Command	Modified	DHCP Snooping Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
interface (VRRP) (deprecated)	Command	Deprecated	VRRP Commands	The interface (VRRP) command has been deprecated. Use the router vrrp (interface) command to configure VRRP and define the interface that will participate in virtual routing to send and receive advertisement messages.
router vrrp (interface)	Command	Modified	VRRP Commands	Use this command to configure VRRP and define the interface that will participate in virtual routing to send and receive advertisement messages. This command allows you to enter the Router Configuration mode. Note that the interface must be specified, and that the interface (VRRP) command has been deprecated from release 5.4.2.
show debugging vrrp	Command	Modified	VRRP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show vrrp	Command	Modified	VRRP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show vrrp counters	Command	Modified	VRRP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show vrrp (session)	Command	Modified	VRRP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
debug epsr	Command	Modified	EPSR Commands	You can now specify the parameter option timer to send EPSR timer information to the console.
epsr priority	Command	New	EPSR Commands	This command sets the priority of an EPSR instance on an EPSR node. Priority is used to prevent superloops forming under fault conditions with particular ring configurations.
show debugging epsr	Command	Modified	EPSR Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show epsr	Command	Modified	EPSR Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show epsr word	Command	Modified	EPSR Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show epsr word counters	Command	Modified	EPSR Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show epsr counters	Command	Modified	EPSR Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show counter ntp	Command	Modified	NTP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ntp associations	Command	Modified	NTP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show ntp status	Command	Modified	NTP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show counter dhcp-client	Command	Modified	Dynamic Host Configuration Protocol (DHCP) Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show counter dhcp-relay	Command	Modified	Dynamic Host Configuration Protocol (DHCP) Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show counter dhcp-server	Command	Modified	Dynamic Host Configuration Protocol (DHCP) Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show dhcp lease	Command	Modified	Dynamic Host Configuration Protocol (DHCP) Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip dhcp binding	Command	Modified	Dynamic Host Configuration Protocol (DHCP) Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip dhcp pool	Command	Modified	Dynamic Host Configuration Protocol (DHCP) Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip dhcp-relay	Command	Modified	Dynamic Host Configuration Protocol (DHCP) Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip dhcp server statistics	Command	Modified	Dynamic Host Configuration Protocol (DHCP) Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ip dhcp server summary	Command	Modified	Dynamic Host Configuration Protocol (DHCP) Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show counter snmp-server	Command	Modified	SNMP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging snmp	Command	Modified	SNMP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show lldp	Command	New	LLDP Commands	This command sets the type of port identifier used to enumerate, that is to count, the LLDP MIB local port entries. This command also enables you to optionally set an interface index to enumerate the LLDP MIB local port entries, if required by your management system.
show debugging lldp	Command	Modified	LLDP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show lldp	Command	Modified	LLDP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#). Console output now displays Port Number Type, which is the type of port identifier to enumerate LLDP MIB local port entries. Port Number Type is set by the new lldp port-number-type command.
show lldp interface	Command	Modified	LLDP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show lldp local-info	Command	Modified	LLDP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show lldp neighbors	Command	Modified	LLDP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show lldp neighbors detail	Command	Modified	LLDP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show lldp statistics	Command	Modified	LLDP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show lldp statistics interface	Command	Modified	LLDP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).

Table B-2: New or Changed Commands(cont.)

Feature		Status	Chapter / Section	Description
show location	Command	Modified	LLDP Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show rmon alarm	Command	Modified	RMON Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show rmon event	Command	Modified	RMON Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show rmon history	Command	Modified	RMON Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show rmon statistics	Command	Modified	RMON Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show counter ping-poll	Command	Modified	Ping-Polling Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show ping-poll	Command	Modified	Ping-Polling Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging sflow	Command	Modified	sFlow Commands	This command is available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show counter stack	Command	Modified	Stacking Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show debugging stack	Command	Modified	Stacking Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show provisioning (stack-member)	Command	Modified	Stacking Commands	This command is now available from the User Exec command mode prompt (awplus>) and the Privileged Exec command mode prompt (awplus#).
show stack resiliencylink	Command	New	Stacking Commands	Use this command to display information about the current status of the resiliency-link across the members of the stack.

Table B-3: New or Changed MIBS

Feature		Status	Chapter / Section	Description
AT-PRODUCT-MIB	MIB	Modified	SNMP MIBs	New object identifiers for Allied Telesis products have been added.
AT-BOARDS-MIB	MIB	Modified	SNMP MIBs	New object identifiers for base CPU and expansion boards have been added.
AT-FILEv2-MIB	MIB	Modified	SNMP MIBs	New objects have been added for copying, moving and deleting files from local, stacked and remote sources.

Introduction

This appendix describes how to install, configure and use the Graphical User Interface (GUI) on switches running the AlliedWare Plus™ OS. The GUI provides extensive monitoring and essential configuration functionality for Allied Telesis switches via a web browser. This document explains how to install the GUI using either an SD card or via a TFTP server.

The GUI functionality is provided via a Java applet file. Before you can use the GUI to manage your switches, you must download the Java applet file, and install it to your switch's Flash file system.

Once the Java applet file is present in your switch's Flash, no specific commands are required to enable the GUI, or to inform the switch which Java applet file to use. Instead, when an incoming browser connection is established with the switch, the switch will automatically send the most recent compatible Java applet file that is present in its Flash file system.

Different versions of the Java applet file will be compatible with different versions of the AlliedWare Plus™ OS. The AlliedWare Plus™ OS automatically determines if a Java applet file is compatible, so the Java applet file that is delivered to your browser will always be compatible with the AlliedWare Plus™ OS version running on the switch to which you have connected.

Note which products and software version the GUI works with, along with PC and browser specifications listed. You may need to install and run the latest Java Runtime Environment that you can download from the Sun site so your browser can fully support the GUI Java applet.

Installing and Setting-up the GUI

This section shows you how to install and setup the AlliedWare Plus™ GUI.

System Requirements

To install and run the AlliedWare Plus™ GUI you will require the following system products and setup:

- PC Platform:
  Windows XP SP2 and up / Windows Vista SP1 and up
- Browser: (must support Java Runtime Environment (JRE) version 6)
  Microsoft Internet Explorer 7.0 and up / Mozilla Firefox 2.0 and up

Installing the GUI to your switch using an SD card

Step 1: Download a GUI Java applet

The GUI Java applet file is available in a compressed (zip) file with the AlliedWare Plus™ Operating System software from the Support area of the Allied Telesis Website: http://www.alliedtelesis.com. Download the Java applet file. This file will have a `.zip` file name extension. You need to extract the Java `.jar` file from the compressed `.zip` file. The version number of the software applet file (`.jar`) gives the earliest version of the software file (`.rel`) that the GUI can operate with.

Step 2: Copy the GUI Java applet **.jar** file to an SD card

Insert the SD card in the SD slot on the front of your switch. Connect to the management port, then login to the switch.

Copy the GUI Java applet to your switch, using the below commands:

```
awplus# copy card:/<filename.jar> flash:/
```

Where `<filename.jar>` is the GUI Java applet file you downloaded in Step 1.

Installing the GUI to Your Switch Via TFTP server

Step 1: Download a GUI Java applet file from the support site:

The GUI Java applet file is available in a compressed (`.zip`) file with the AlliedWare Plus™ Operating System software from the Support area of the Allied Telesis Website: http://www.alliedtelesis.com. Download the Java applet file. This file will have a `.zip` file name extension. You need to extract the Java `.jar` file from the compressed `.zip` file. The version number of the software applet file (.jar) gives the earliest version of the software file (`.rel`) that the GUI can operate with.

Step 2: Copy the GUI applet

Copy the GUI applet .jar file onto a TFTP server. Ensure this TFTP server is enabled and ready for the switch. Connect to the management port of the switch, then login to the switch. Do not connect to the management port of the TFTP server.

Step 3: Copy the GUI Java applet to your switch

Use the following commands to copy the GUI Java applet to your switch:

```
awplus# copy tftp://<server-address>/
        <filename.jar> flash:/
```

Where *<server-address>* is the IP address for the TFTP server, and where *<filename.jar>* is the GUI Java applet file you downloaded in Step 1.

Setting up your switch and logging into the GUI

Step 1: Assign the IP addresses:

Use the following commands to configure your switch with an appropriate IP address:

```
awplus# configure terminal
awplus(config)# interface vlan1
awplus(config-if)# ip address <address>/<prefix-
length>
```

Where *<address>* is the IP address that you will subsequently browse to when you connect to the GUI Java applet. For example, to give the switch an IP address of `192.168.2.6`, and a subnet mask of `255.255.255.0`, use the following command:

```
awplus(config-if)# ip address 192.168.2.6/24
```

Step 2: Configure the Default Gateway

In necessary, use the following commands to configure the default gateway.

```
awplus(config-if)# exit
awplus(config)# ip route 0.0.0.0/0 <gateway address>
```

Where *<gateway-address>* is the IP address for your gateway device. Note that you do not need to define a default gateway if you browse to the switch from within its own subnet.

Step 3: Create a user account

In order to log into the GUI, you must first create a user account. Use the following command to setup a user account:.

```
awplus(config)# username <username> privilege 15
password <password>
```

Note that you can create multiple users to log into the GUI. See the AlliedWare Plus Software Reference for information about the username command. The switch must be configured with a local database user, or the switch must be configured to remotely authenticate users with either TACACS+ or RADIUS.

Step 4: Ensure HTTP service is enabled

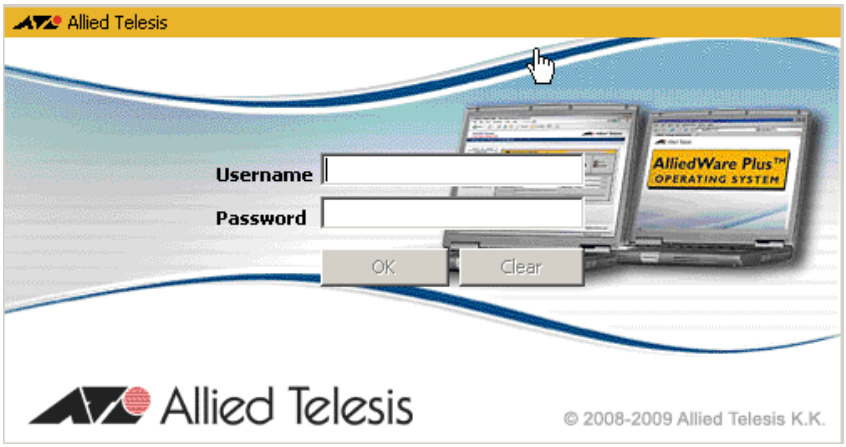
The HTTP service needs to be enabled on the switch before it accepts connections from a web browser. The HTTP service is enabled by default. However, if the HTTP service has been disabled then you must enable the HTTP service again. If the HTTP service is disabled then use the following command to enable the HTTP service:

```
awplus(config)# service http
```

See the AlliedWare Plus™ Software Reference for information about the service http command.

Step 5: Logging into the GUI

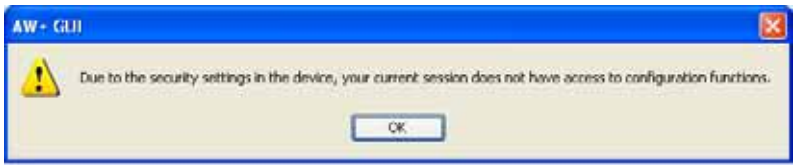
Start a browser then enter the IP address you configured in Step 3 as the URL. You will then be presented with a login screen after the GUI Java applet has started. You can then Log in with the username and password that you defined previously in Step 3.



Step 6: Security Check

You may also be presented with a security check password prompt. This will occur when you have logged into the GUI with a user that is configured on the switch and have a privilege level of less than 15, or if the switch has been configured to authenticate enable passwords via TACACS+ using the aaa authentication enable default group tacacs+ command.

You must enter the privilege level 15 enable password configured on the switch to access GUI configuration dialogs. If you enter an incorrect enable password, or no privilege level 15 enable password has been configured, the a message is shown stating you can use the GUI to monitor the switch, but not to configure the switch.



Using the GUI

This section explains how to use the AlliedWare Plus™ GUI. It assumes that you have installed the GUI on your switches and have the setup the browser on your PC. This procedure is covered in "Installing and Setting-up the GUI" on page C.4.

In this section each screen is presented by its tab name and explains the content of the screen components.

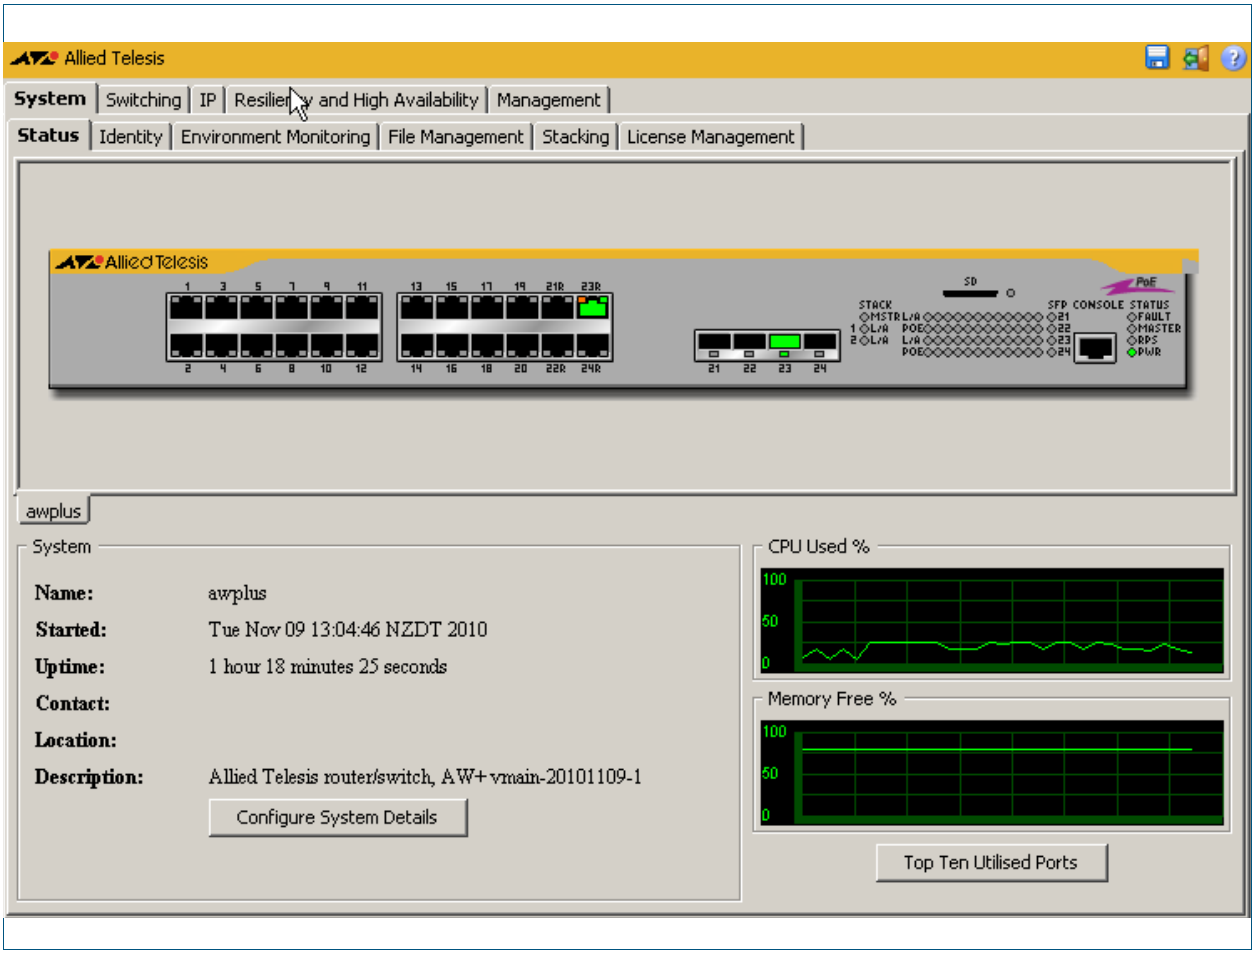
System > Status

The System > Status menu tab enables you to display and configure basic system information.

The CPU Used % and Memory Free % graphs provide a brief history of CPU and memory usage.

Note: For systems equipped and configured using VCStack, there is a separate tab for each stack member with the system name displayed on each tab.

Menu Tab Figure C-1: Example showing the **System > Status** menu tab:



Description

Display Label / Field	Description
System / Name	Specifies the network name of the system, as set with the 'hostname' command in the CLI.
System / Started	Date and time the switch was last booted.
System / Uptime	Elapsed time since the last boot.
System / Contact	Contact details for system maintenance.
System / Location	Location of the switch
System / Description	Description of the switch, including manufacturer, model, and software version.
Top Ten Utilised Ports	Displays a sorted list of the ten most used ports listed by port and its utilization. You can rearrange and resort the list by port or utilization.

Description

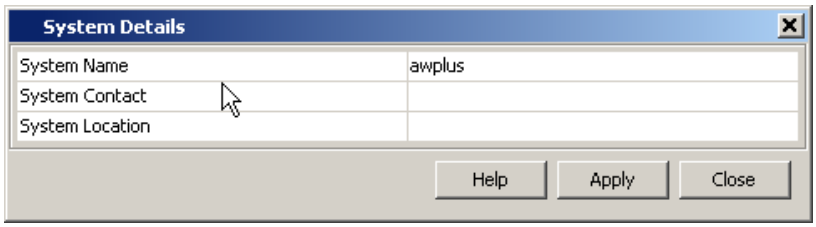
Configuration Button / Field	Description
System Time & Date (icon)	Add or modify System Date, System Time, UTC Time Zone Offset.
Configure System Details	Add or modify System Name, System Contact, System Location.
Configure System Details / System Name	Configures the network name of the system.
Configure System Details / System Contact	Configures the contact information for the system, from 0 to 255 characters long. Valid characters are any printable characters and spaces.
Configure System Details / System Location	Configures the location of the system, from 0 to 255 characters long. Valid characters are any printable characters and spaces.

System > Status > System Details

The System > Status > System Details dialog allows you to configure basic system information.

Configuration Dialog

Figure C-2: Example showing **System > Status > System Details** dialog:



Description

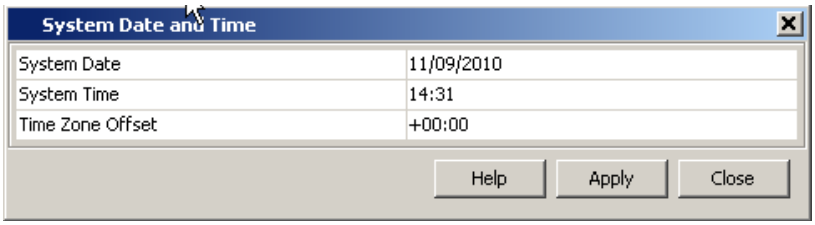
Label / Field / Button	Description
System Name	Enter the network name of the system.
System Contact	Enter the contact information for the system, from 0 to 255 characters long. Valid characters are any printable characters and spaces.
System Location	Enter the location of the system, from 0 to 255 characters long. Valid characters are any printable characters and spaces.

System > Status > System Date and Time

The System > Status > System Date and Time dialog allows you to configure the date and time for the switch.

Configuration Dialog

Figure C-3: Example showing **System > Status > System Date and Time** dialog:



Description

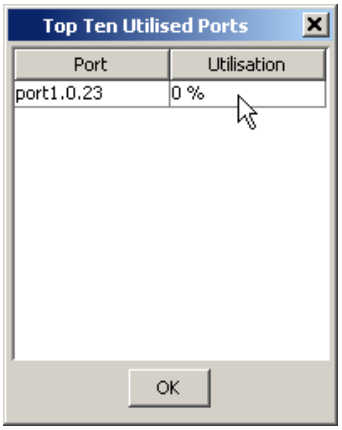
Label / Field / Button	Description
System Date	Enter the current system date in month, day, and year format.
System Time	Enter the local time for the system clock in hours and minutes.
Time Zone Offset	Enter the offset to the UTC (Coordinated Universal Timezone) for a local timezone in hours and minutes.

System > Status > Top Ten Utilised Ports

The System > Status > Top Ten Utilised Port dialog allows you to monitor port utilisation on the switch.

Configuration Dialog

Figure C-4: Example showing **System > Status > Top Ten Utilised Ports** dialog:



Description

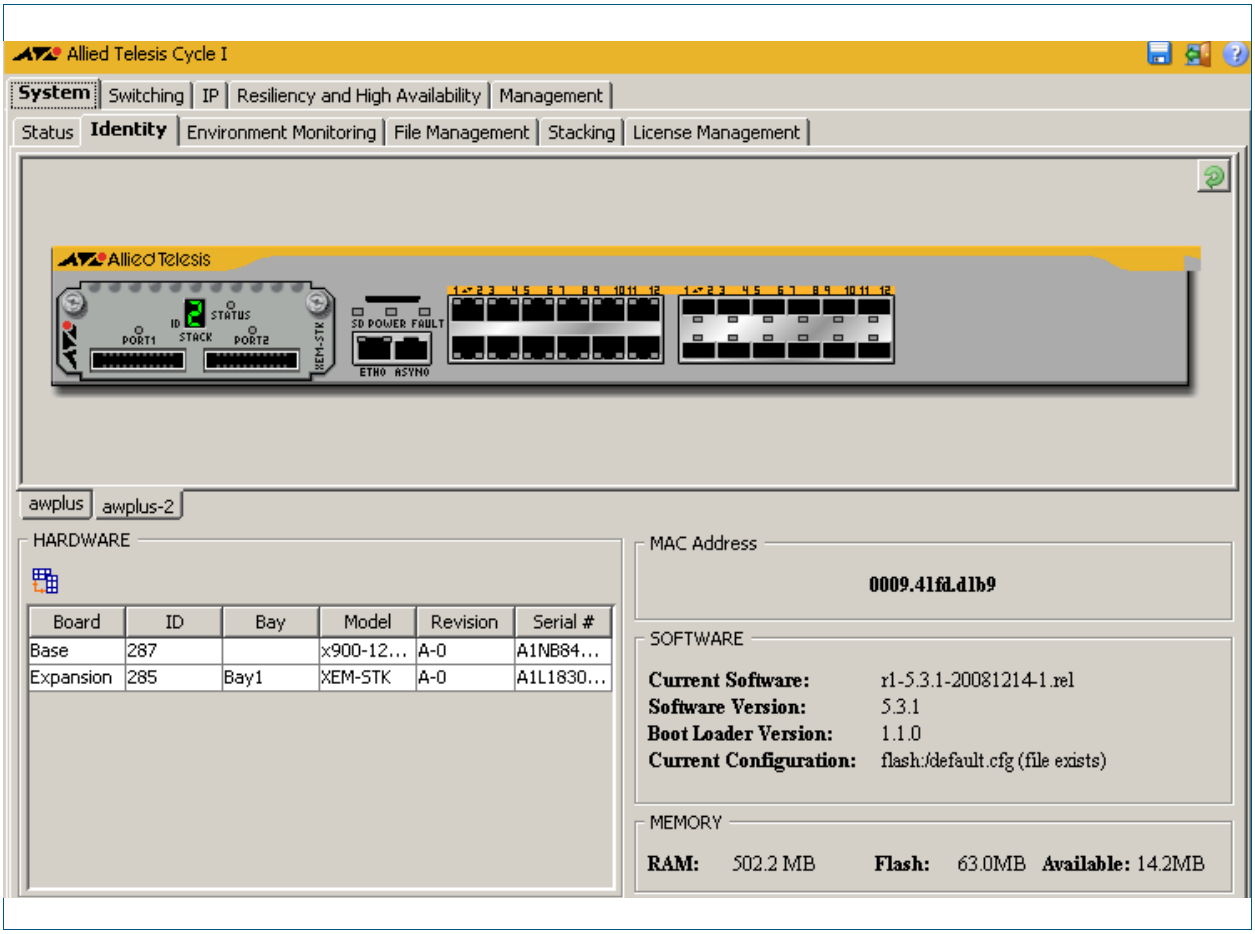
Label / Field / Button	Description
`Port`	Displays up to ten ports that are used the most on the switch. You can sort by ascending or descending port order.
`Utilisation`	Displays the utilisation percentage for the port. You can sort by ascending or descending utilisation percentage.

System > Identity

The System > Identity menu tab displays physical properties, software version and configuration file name.

Note: For systems equipped and configured using VCStack there is a separate tab for each stack member with the system name displayed on each tab.

Menu Tab Figure C-5: Example showing the **System > Identity** menu tab:



Description

Label / Field / Button	Description
HARDWARE	Displays the board, ID, bay, model, revision and serial number of the switch main board and any installed XEMs.
MAC Address	Displays the MAC Address of the switch in hexadecimal in the format HHHH.HHHH.HHHH.

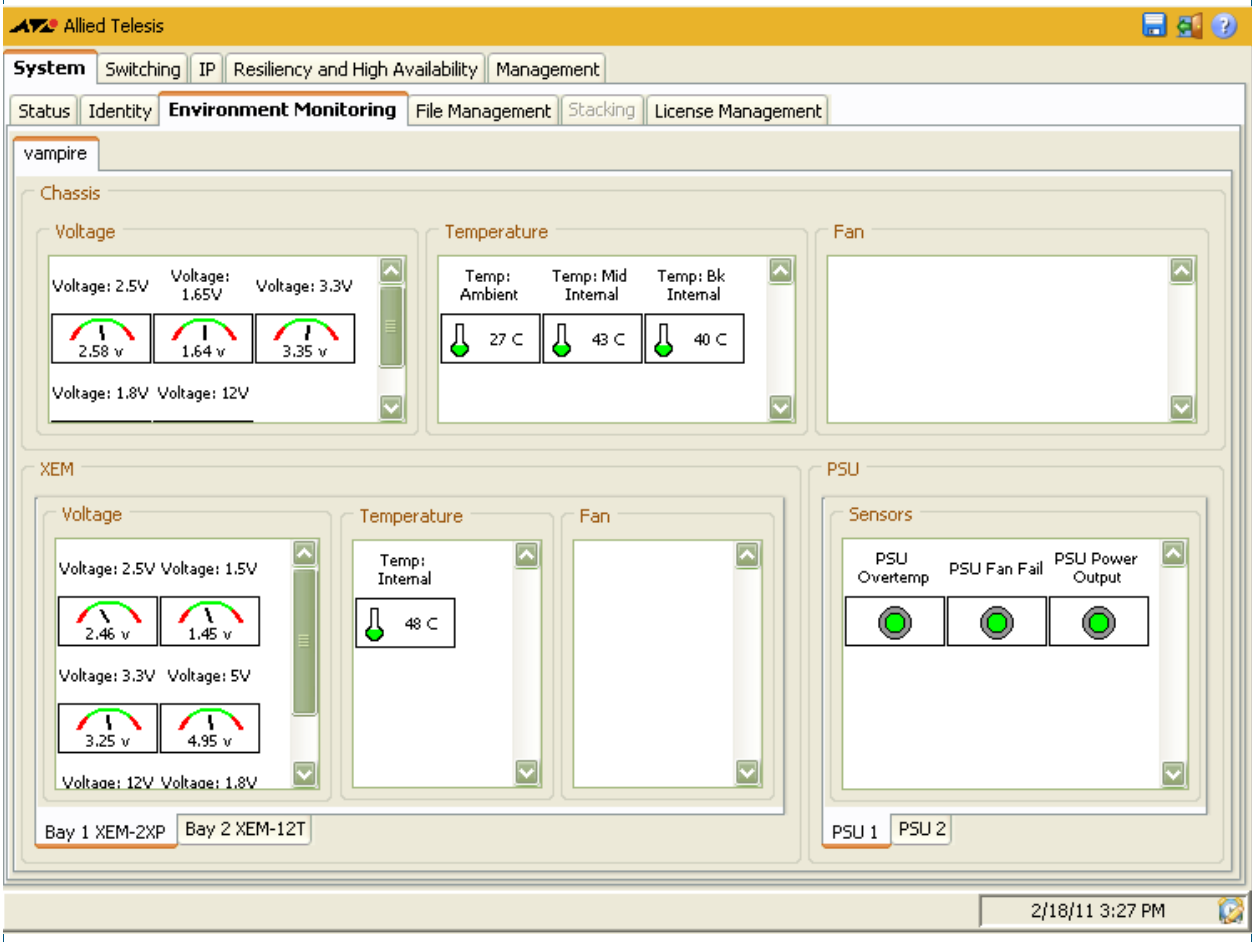
Label / Field / Button(cont.)	**Description**(cont.)
SOFTWARE	Displays the software release file name, software version, boot loader version, and configuration file name loaded on the switch.
MEMORY	Displays the amount of installed RAM and Flash, plus the remaining Flash available on the switch.

System > Environment Monitoring

The System > Environment Monitoring menu tab allows you to display the status of the environmental properties, such as all voltages and temperatures, which the system monitors.

Note: For systems equipped and configured using VCStack there is a separate tab for each stack member with the system name displayed on each tab.

Menu Tab Figure C-6: Example showing the **System > Environment Monitoring** menu tab:



Description

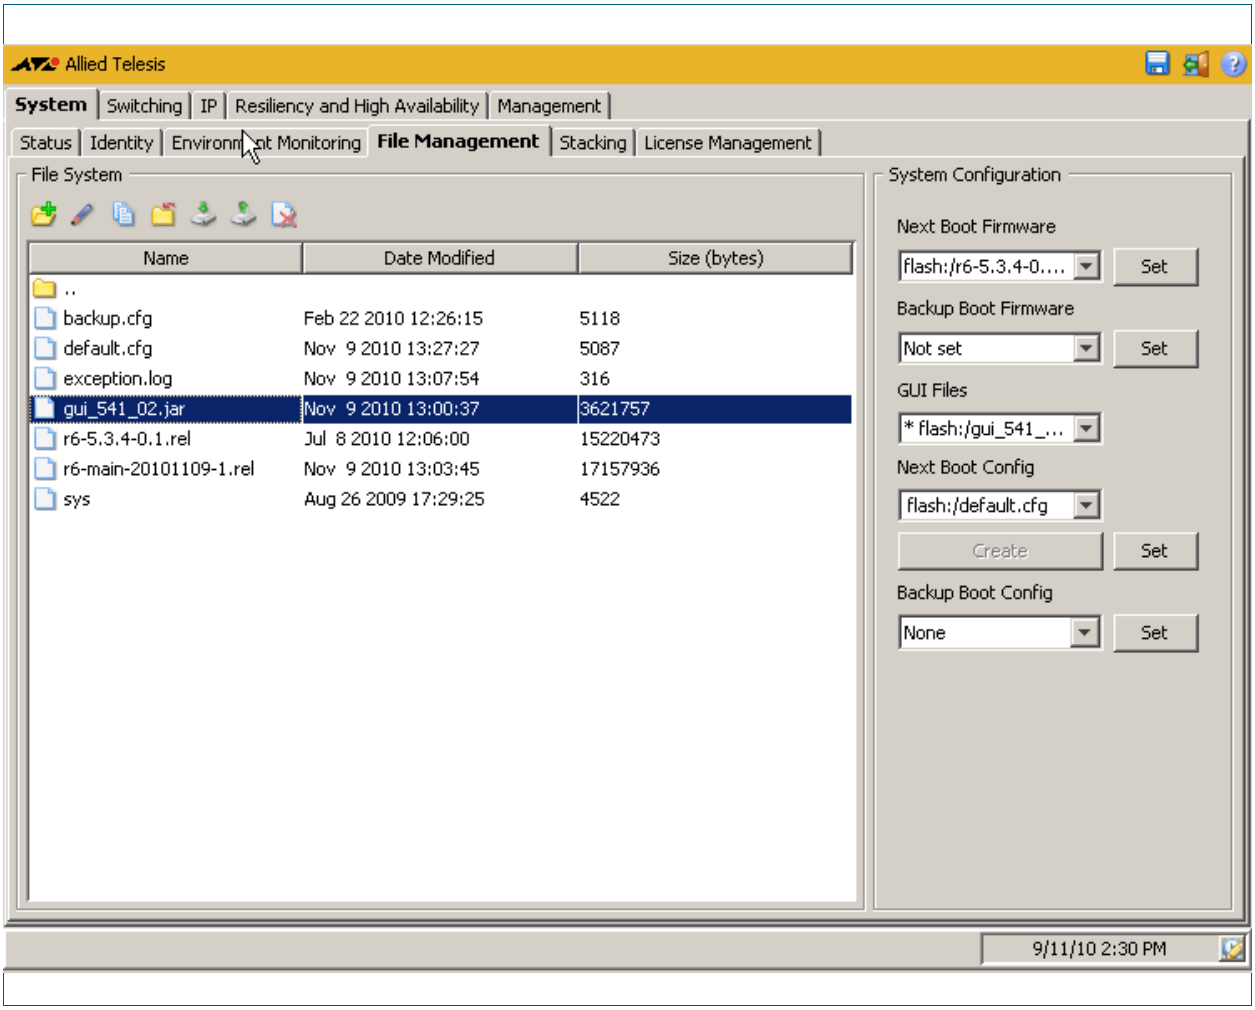
Label / Field / Button	Description
`Chassis`	Displays the operational status of chassis voltages and temperatures for the switch.
`Fan`	Displays the operational status of the switch fans.

Label / Field / Button(cont.)	**Description**(cont.)
XEM	Displays the operational status of voltages, temperatures, and fans for any installed XEMs.
PSU	Displays the operational status of temperatures and fans for any installed pluggable PSUs.

System > File Management

The System > File Management menu tab allows you to create, copy, delete, upload or download boot and backup release and configuration files to and from the switch. From 5.4.1 release onwards, you can specify fallback or backup release and configuration files in case the boot release or configuration files become corrupted, and you can also specify the boot release and configuration files to boot directly from SD card or to boot from flash.

Menu Tab Figure C-7: Example showing the **System > File Management** menu tab:



Description: File System

Label / Field / Button	Description
File System	Displays file names, file dates, and file sizes of files in Flash, NVS or SD card. Note that only SD card files that are resident on the stack master are shown. Also, only files that have a total URL length of 112 characters or less are displayed. The URL is the path to the file and is of the form <hostname>-<stack_id>/<filesystem>:/<pathname>, for example, awplus-1/flash:/test.cfg. The GUI will immediately show all file changes to the NVS and Flash filesystems, regardless of how they have been made, either via the GUI or CLI. However, the SD card filesystem is treated differently as it is not permanently mounted. The GUI will only update SD card files when the card is inserted/deleted, or when the changes are made via the GUI. They are not updated if modified via the CLI. The buttons shown below the File System label also allow you upload, download, move, copy, and delete files respectively.
File System / Add Folder	Select the folder you want to create a new sub-folder in then click on the Add Folder button located directly below the File System label.
File System / Rename File	Select the file you want to rename then click on the Rename File or Folder button located directly below the File System label.
File System / Copy File	Select the file you want to copy then click on the Copy File button located directly below the File System label. Choose the Destination Folder from the drop down list in the Copy File dialog then select OK to copy the file to the chosen destination.
File System / Move File	Select the file you want to move then click on the Move File button located directly below the File System label. Choose the Destination Folder from the drop down list in the Move File dialog then select OK to move the file to the chosen destination.
File System / Download File	Select the file you want to download then click on the Download File button located directly below the File System label.
File System / Upload File	Click on the Upload File button located directly below the File System label then select the file you want to upload.
File System / Delete File	Select the file or folder you want to delete then click on the Delete File button located directly below the File System label.

Description: System Configuration

Label / Field / Button	Description
System Configuration	Configures running and backup software, GUI software, and configuration files in Flash or card memory available on the switch.
System Configuration / Next Boot Firmware	Choose the Next Boot Firmware .rel file and path from the drop down list then click Set to make this file the firmware that starts after reboot. From 5.4.1 release onwards, you can set a Next Boot Firmware .rel file to boot directly from an SD card.

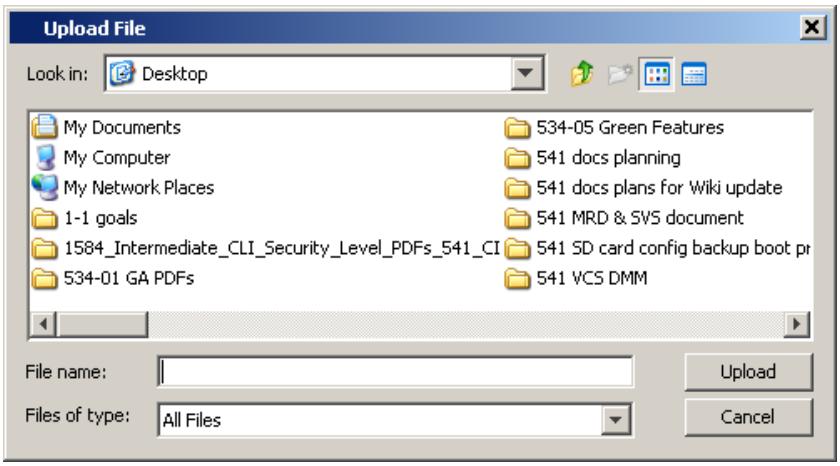
Label / Field / Button(cont.)	**Description**(cont.)
System Configuration / Backup Boot Firmware	Choose the Backup Boot Firmware `.rel` file and path from the drop down list then click Set to boot from this file at reboot. A Backup Boot Firmware .rel file is used instead of the Next Boot Firmware `.rel` file if the Next Boot Firmware `.rel` file is corrupted.
System Configuration / GUI Files	Displays the GUI file name and file location on the switch and indicates the currently running GUI file with a prefixed asterisk (e.g. `* flash:/gui_534_07.jar`). Note that you cannot set the GUI version from within the GUI itself. See the GUI installation instructions in *Appendix C: GUI Reference* of the current *AlliedWare Plus Software Reference* to install GUI files. The latest version of the GUI .jar file loaded is run by the switch automatically.
System Configuration / Next Boot Config	Choose the Next Boot Config `.cfg` file and path from the drop down list then click Set to make this file the Config `.cfg` file that the switch uses at reboot. From 5.4.1 release onwards, you can set a Next Boot Config `.cfg` file to load directly from an SD card.
System Configuration / Backup Boot Config	Choose the Backup Boot Config Files .cfg file and path from the drop down list then click Set to make boot from this file at reboot. A Backup Boot Config `.cfg` file is used instead of the Next Boot config `.cfg` file if the Next Boot Config `.cfg` file is corrupted.

System > File Management > Upload File

The System > File Management > Upload File dialog allows you to upload files (e.g. release and configuration files) from a client device to the switch. Select the Upload File button below the File System label to access this dialog.

Configuration Dialog

Figure C-8: Example showing **System > File Management > Upload File** dialog:



Description

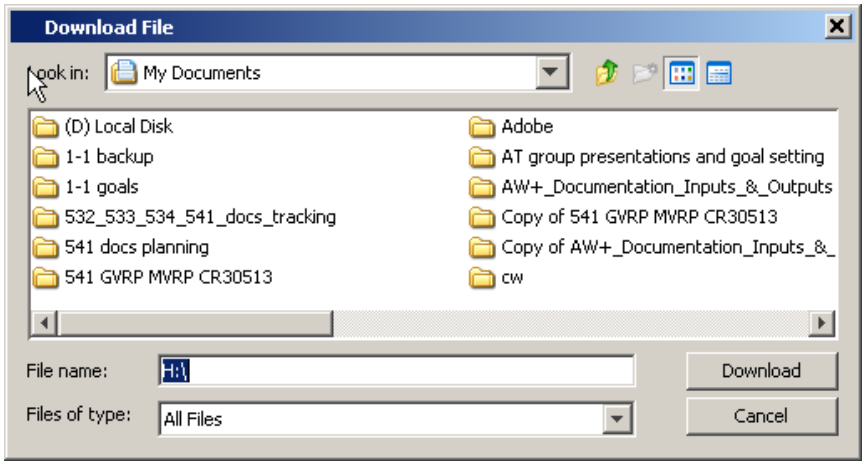
Label / Field / Button	Description
`Destination Folder`	Select the destination folder to upload the selected file from. An uploading progress bar displays after clicking the Upload button.

System > File Management > Download File

The System > File Management > Download File dialog allows you to download files (e.g. release and configuration files) from the switch to a client device. Select the Download File button below the File System label to access this dialog.

Configuration Dialog

Figure C-9: Example showing **System > File Management > Download File** dialog:



Description

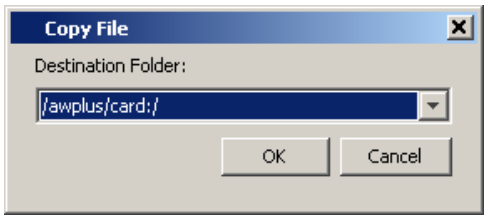
Label / Field / Button	Description
`Destination Folder`	Select the destination folder to download the selected file to. A downloading progress bar displays after clicking the Download button.

System > File Management > Copy File

The System > File Management > Copy File dialog allows you to copy files (e.g. release and configuration files). Select the Copy File button below the File System label to access this dialog.

Configuration Dialog

Figure C-10: Example showing **System > File Management > Copy File** dialog:



Description

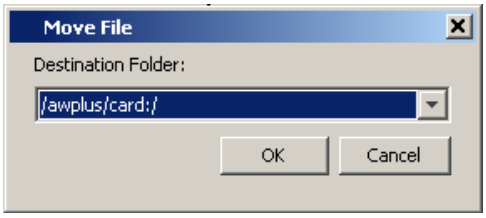
Label / Field / Button	Description
`Destination Folder`	Select the destination folder to copy the selected file to. A copying progress bar displays after clicking the OK button.

System > File Management > Move File

The System > File Management > Move File dialog allows you to move files (e.g. release and configuration files). Select the Move File button below the File System label to access this dialog.

Configuration Dialog

Figure C-11: Example showing **System > File Management > Move File** dialog:



Description

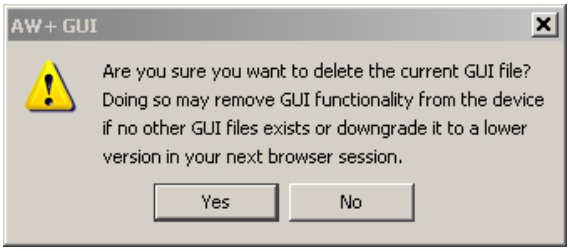
Label / Field / Button	Description
`Destination Folder`	Select the destination folder to move the selected file to. A moving progress bar displays after clicking the OK button.

System > File Management > Delete File

The System > File Management > Delete File dialog allows you to delete files (e.g. release and configuration files). Select the Delete File button below the File System label to access this dialog.

Configuration Dialog

Figure C-12: Example showing **System > File Management > Delete File** dialog:



Description

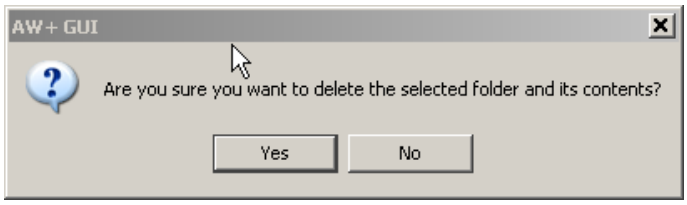
Label / Field / Button	Description
`Yes`	Confirm selected file deletion operation.
`No`	Cancel selected file deletion operation.

System > File Management > Delete Folder

The System > File Management > Delete Folder dialog allows you to delete folders in the flash or SD card file system containing files (e.g. release and configuration files). Select the Delete Folder button below the File System label to access this dialog.

Configuration Dialog

Figure C-13: Example showing **System > File Management > Delete Folder** dialog:



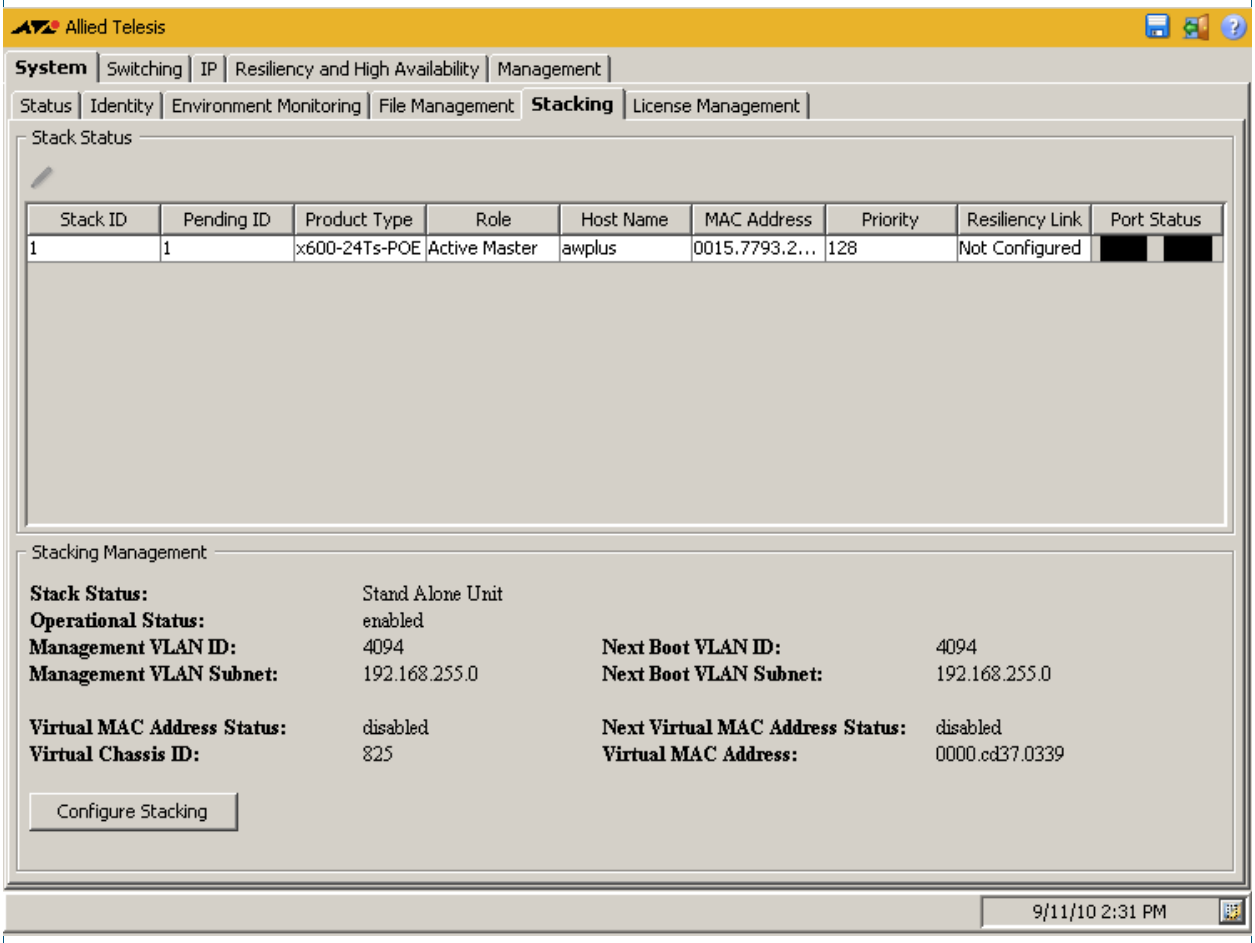
Description

Label / Field / Button	Description
Yes	Confirm selected folder deletion operation.
No	Cancel selected folder deletion operation.

System > Stacking

The System > Stacking menu tab allows you to display and monitor a summary of the identity and status of stack members, plus you can also configure the VLAN ID and IP subnets used for internal VCStack communication.

Menu Tab Figure C-14: Example showing the **System > Stacking** menu tab:



Description: Stacking Management

Label / Field / Button	Description
`Stacking Management / Stack Status`	The stack's overall status. Note that a warning is issued if the stack is not connected in a standard ring topology.
`Stacking Management / Operational Status`	The operational status of the stack. Can be: enabled (1), disabled (2).
`Stacking Management / Management VLAN ID`	The VLAN ID currently used for stack management. The default stack management VLAN ID is 4094.
`Stacking Management / Next Boot VLAN ID`	The VCS management VLAN ID to be assigned after the next reboot.

Label / Field / Button(cont.)	**Description**(cont.)
`Stacking Management / Management VLAN Subnet`	The VLAN subnet currently used for stack management.
`Stacking Management / Next Boot VLAN Subnet`	The stacking management VLAN subnet address after rebooting.
`Stacking Management / Virtual MAC Address Status`	Indicates whether the virtual MAC address is enabled or disabled.
`Stacking Management / Next Virtual MAC Address Status`	Indicates whether the next virtual MAC address is enabled or disabled.
`Stacking Management / Virtual Chassis ID`	Displays the current virtual chassis ID.
`Stacking Management / Virtual MAC Address`	Displays the virtual MAC address used by the stack.
`Configure Stacking`	Configures the VCS management VLAN ID, the subnet address of the VCS management VLAN, and the Virtual MAC Address Status.

Description: Stack Status

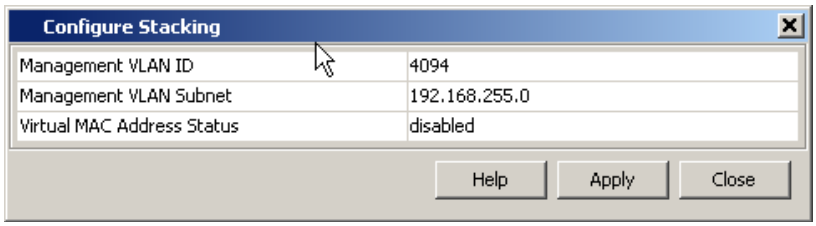
Label / Field / Button	Description
`Stack Status / Stack ID`	The Stack member ID.
`Stack Status / Pending ID`	The Stack member ID to be assigned to the device after the next reboot.
`Stack Status / Product Type`	The Stack member product type; for example, SwitchBlade x908.
`Stack Status / Role`	Stack member's role in the stack (either Active Master or Backup Member).
`Stack Status / Host Name`	The host name of the Stack member.
`Stack Status / MAC Address`	Stack member's hardware MAC address. Note that frames from devices within a stacked virtual chassis will carry the source address of the stack master.
`Stack Status / Priority`	The priority for election of stack master (0 to 255). The lowest number has the highest priority. Note that where stack members have the same priority setting, the switch with the lowest MAC address will become the stack master.
`Stack Status / Resiliency Link`	Status of the stack members resiliency link. Can be one of: `Configured`, `Successful`, `Failed`, `Not Configured`.
`Stack Status / Port Status`	When the rectangle is colored GREEN, it means that the port has a learned neighbor connected. Note that the number in the rectangle indicates the stack ID of the learned neighbor connected to the port. When the rectangle is colored BLACK then the port status is down. When the rectangle is colored RED then Operational Status for the port has been set to disabled.

System > Stacking > Configure Stacking

The System > Stacking > Configure Stacking dialog allows you to configure the VLAN ID and IP subnets used for internal VCStack communication.

Configuration Dialog

Figure C-15: Example showing **System > Stacking > Configure Stacking** dialog:



Description

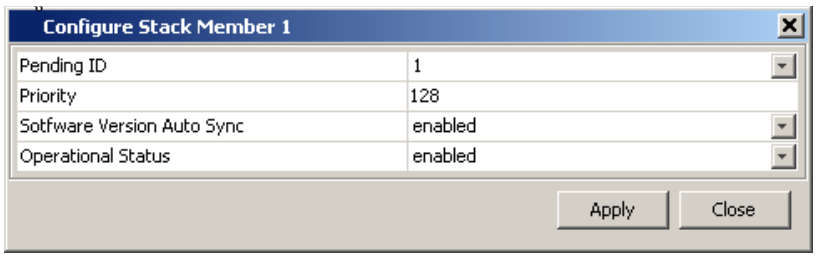
Label / Field / Button	Description
`Management VLAN ID`	Enter the VLAN ID for stack management. The default stack management VLAN ID is 4094.
`Management VLAN subnet`	Enter the subnet address of the VCS management VLAN.
`Virtual MAC Address Status`	Select the status for the Virtual MAC Addressing feature, which can be set to `disabled` or `enabled` from the drop down list.

System > Stacking > Configure Stack Member

The System > Stacking > Configure Stack Member dialog allows you to configure the Pending ID, Priority, Software Version Auto Synchronization and Operational Status used for internal VCStack communication.

Configuration Dialog

Figure C-16: Example showing **System > Stacking > Configure Stack Member** dialog:



Description

Label / Field / Button	Description
`Pending ID`	Enter the Pending ID for the stack member.
`Priority`	Enter the Priority for the stack member.

Label / Field / Button	Description(cont.)
Software Version Auto Sync	Select the enabled or disabled options to enable or disable the Software Version Auto Synchronization feature for the stack member.
Operational Status	Select the enabled or disabled options to enable or disable the stack member.

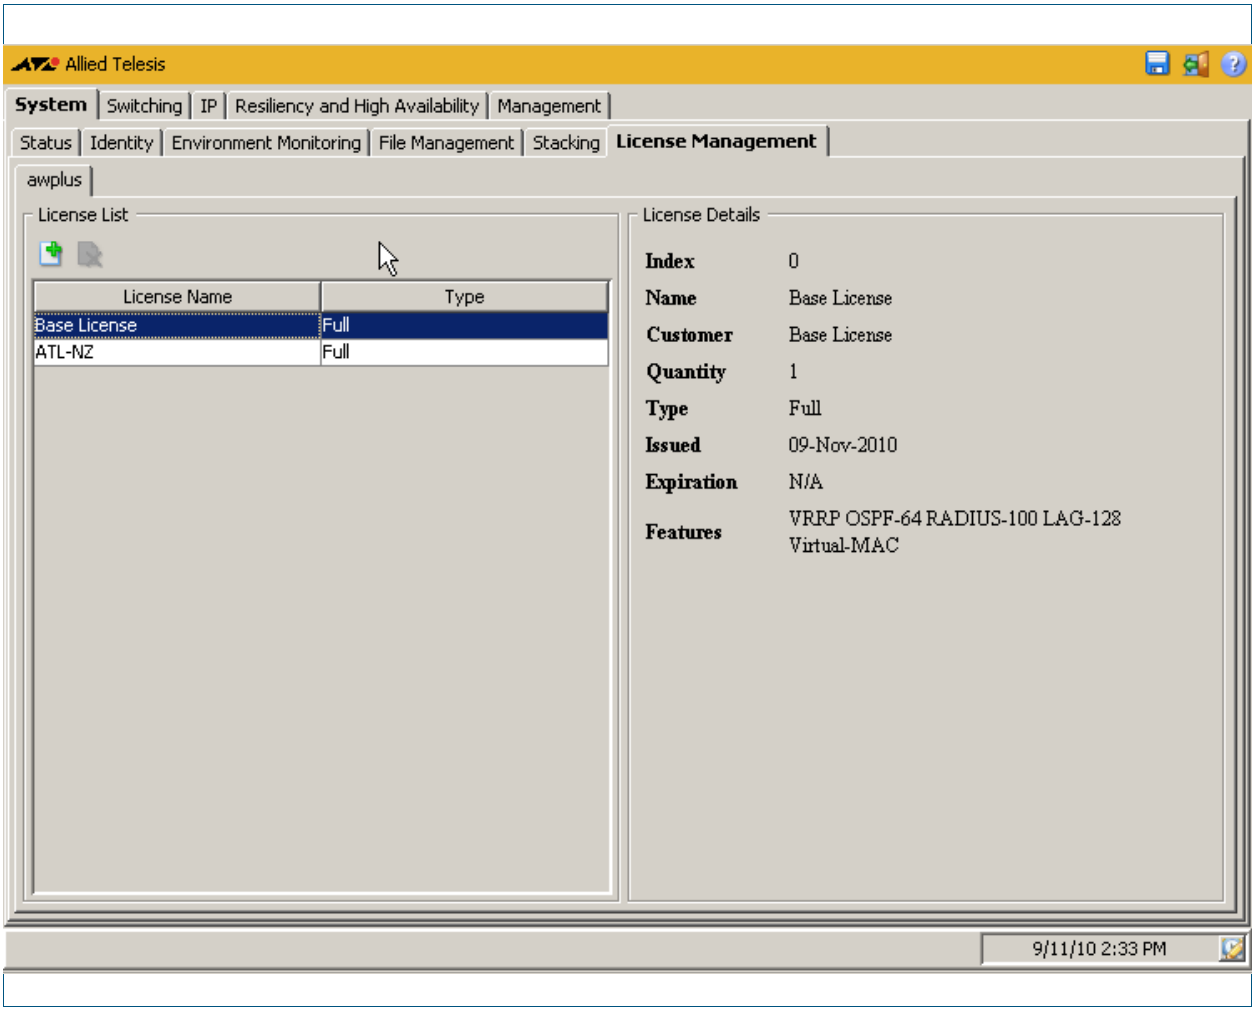
System > License Management

The System > License Management menu tab allows you to view, add and delete feature licenses.

Note: For systems equipped and configured using VCStack there is a separate tab for each stack member with the system name displayed on each tab.

Note: If a license is added to, or deleted from, a stack member then the same action must be taken on all other stack members. Otherwise incompatible licensing will occur and affected devices will not rejoin the stack following a reboot.

Menu Tab Figure C-17: Example showing the **System > License Management** menu tab:



Description

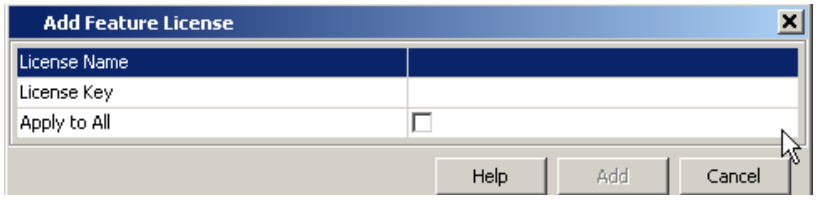
Label / Field / Button	Description
License List / License Name	Name of the license bundle.
License List / Type	The type of license activated on the switch: full or temporary.
License Details / Index	Index identifying entry.
License Details / Name	Name of the license bundle.
License Details / Customer	Customer name.
License Details / Quantity	Quantity of licenses included in the feature key.
License Details / Type	Full or temporary license types.
License Details / Issued	Date the key was generated.
License Details / Expiration	Expiry date for a temporary license.
License Details / Features	List of features enabled by the license.

System > License Management > Add Feature License

The System > License Management > Add Feature License dialog allows you add feature licenses by specifying the license name and the license key. You can add a license for all the stack members or for a single stack member.

Configuration Dialog

Figure C-18: Example showing **System > License Management > Add Feature License** dialog:



Description

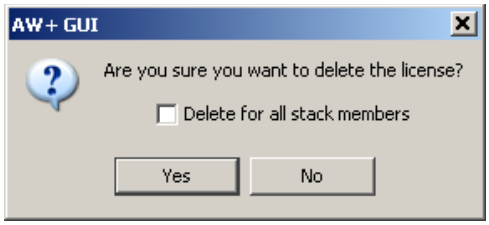
Label / Field / Button	Description
License Name	Enter the license name of the software feature.
License Key	Enter the encrypted license key to enable this software feature.
Apply to All	Select the checkbox to apply the license to all the stack members.

System > License Management > Delete Feature License

The System > License Management > Delete Feature License dialog allows you delete feature licenses by specifying the license name and the license key. You can delete a license for all the stack members or for a single stack member.

Configuration Dialog

Figure C-19: Example showing **System > License Management > Delete Feature License** dialog:



Description

Label / Field / Button	Description
`Delete for all stack members`	Select the checkbox to delete the license for all the stack members.

Switching > Ports

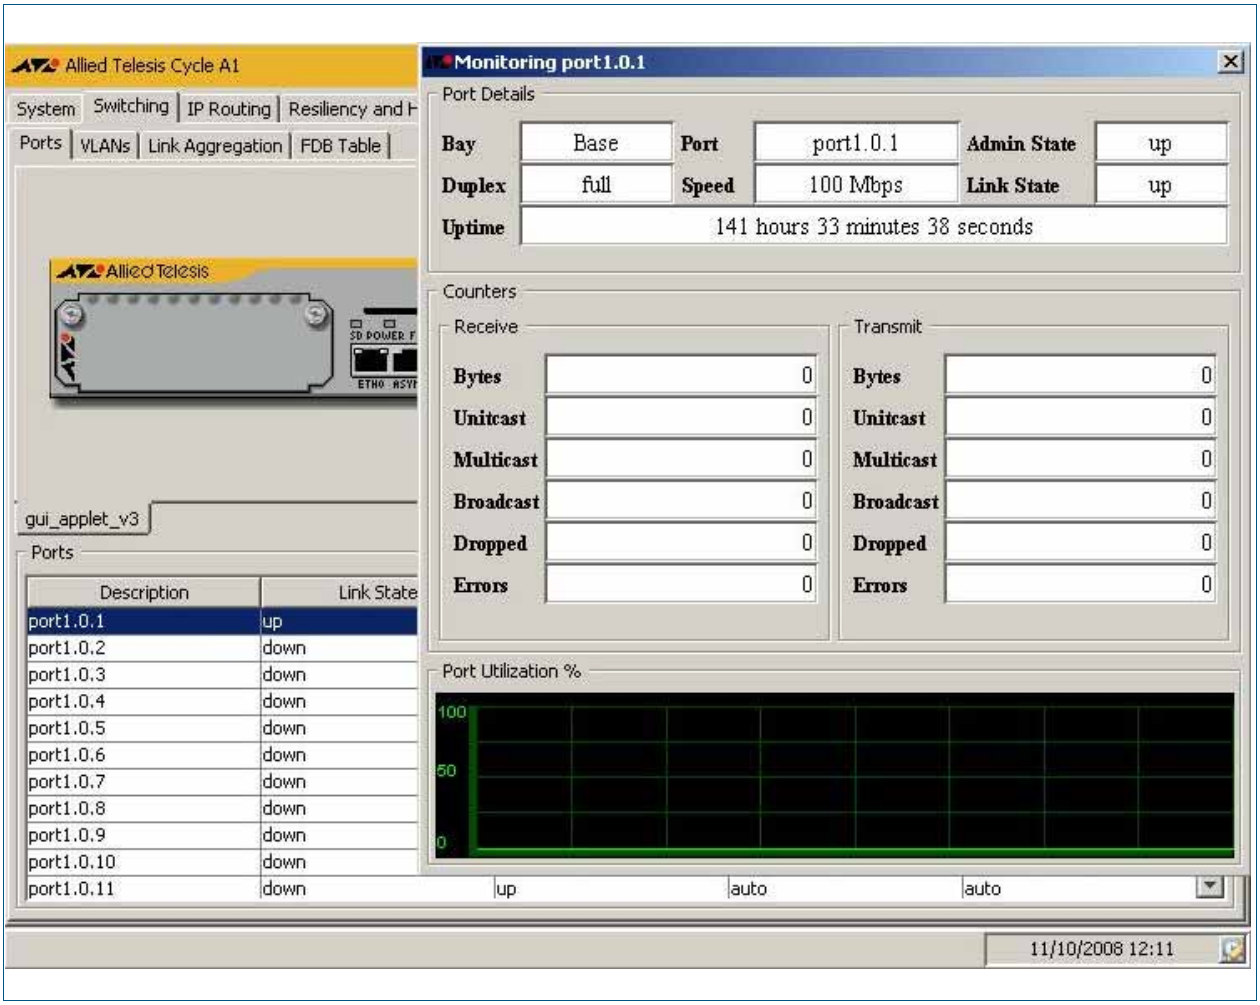
The Switching > Ports menu tab allows you to view, and configure Layer 1 properties:

- Right-clicking a port allows you to select monitoring or configuration dialogs for the selected port.
- The monitoring dialog displays port status, statistics and a brief utilization history.
- The configuration dialog allows you to configure Administrative State, Auto Negotiation, Speed and Duplex settings for the port.

Note: Speed and Duplex settings can only be changed if Auto Negotiation is disabled.

Note: For systems equipped and configured using VCStack there is a separate tab for each stack member with the system name displayed on each tab.

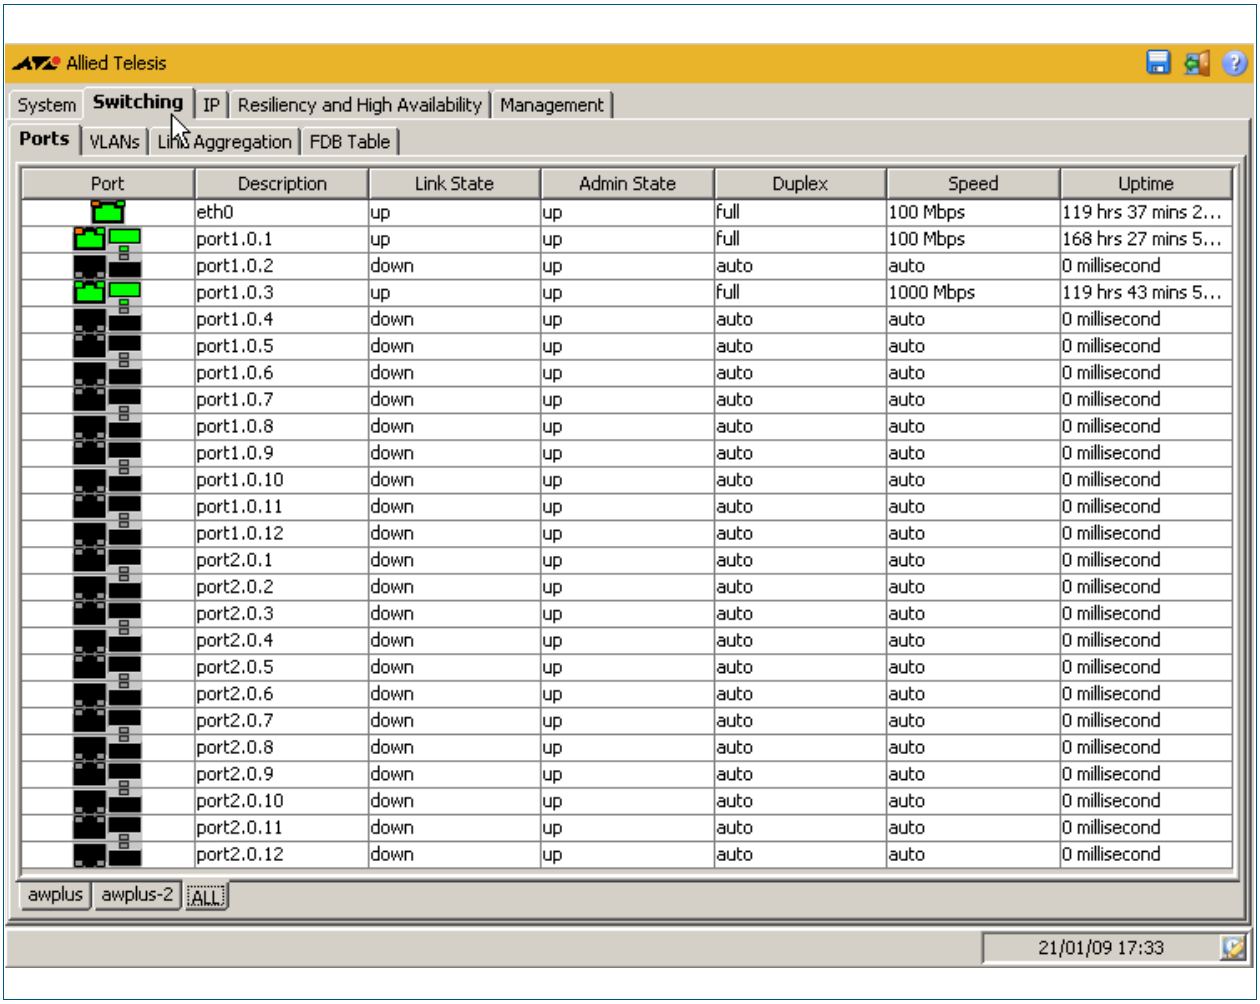
Menu Tab Figure C-20: Example showing the **Switching > Ports** menu tab



Description

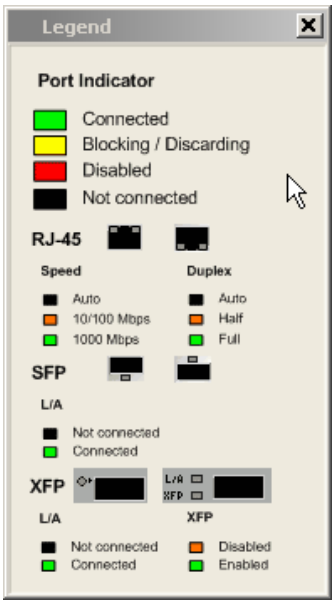
Label / Field / Button	Description
Ports	Displays port number, description of the port, link and administrative status, duplex mode, speed and uptime (in milliseconds) for the selected port.

Menu Tab Figure C-21: Example showing the **Switching > Ports > ALL** menu tab:



Port	Description	Link State	Admin State	Duplex	Speed	Uptime
	eth0	up	up	full	100 Mbps	119 hrs 37 mins 2...
	port1.0.1	up	up	full	100 Mbps	168 hrs 27 mins 5...
	port1.0.2	down	up	auto	auto	0 millisecond
	port1.0.3	up	up	full	1000 Mbps	119 hrs 43 mins 5...
	port1.0.4	down	up	auto	auto	0 millisecond
	port1.0.5	down	up	auto	auto	0 millisecond
	port1.0.6	down	up	auto	auto	0 millisecond
	port1.0.7	down	up	auto	auto	0 millisecond
	port1.0.8	down	up	auto	auto	0 millisecond
	port1.0.9	down	up	auto	auto	0 millisecond
	port1.0.10	down	up	auto	auto	0 millisecond
	port1.0.11	down	up	auto	auto	0 millisecond
	port1.0.12	down	up	auto	auto	0 millisecond
	port2.0.1	down	up	auto	auto	0 millisecond
	port2.0.2	down	up	auto	auto	0 millisecond
	port2.0.3	down	up	auto	auto	0 millisecond
	port2.0.4	down	up	auto	auto	0 millisecond
	port2.0.5	down	up	auto	auto	0 millisecond
	port2.0.6	down	up	auto	auto	0 millisecond
	port2.0.7	down	up	auto	auto	0 millisecond
	port2.0.8	down	up	auto	auto	0 millisecond
	port2.0.9	down	up	auto	auto	0 millisecond
	port2.0.10	down	up	auto	auto	0 millisecond
	port2.0.11	down	up	auto	auto	0 millisecond
	port2.0.12	down	up	auto	auto	0 millisecond

Legend Figure C-22: Example showing S**witching > Ports > Legend**:

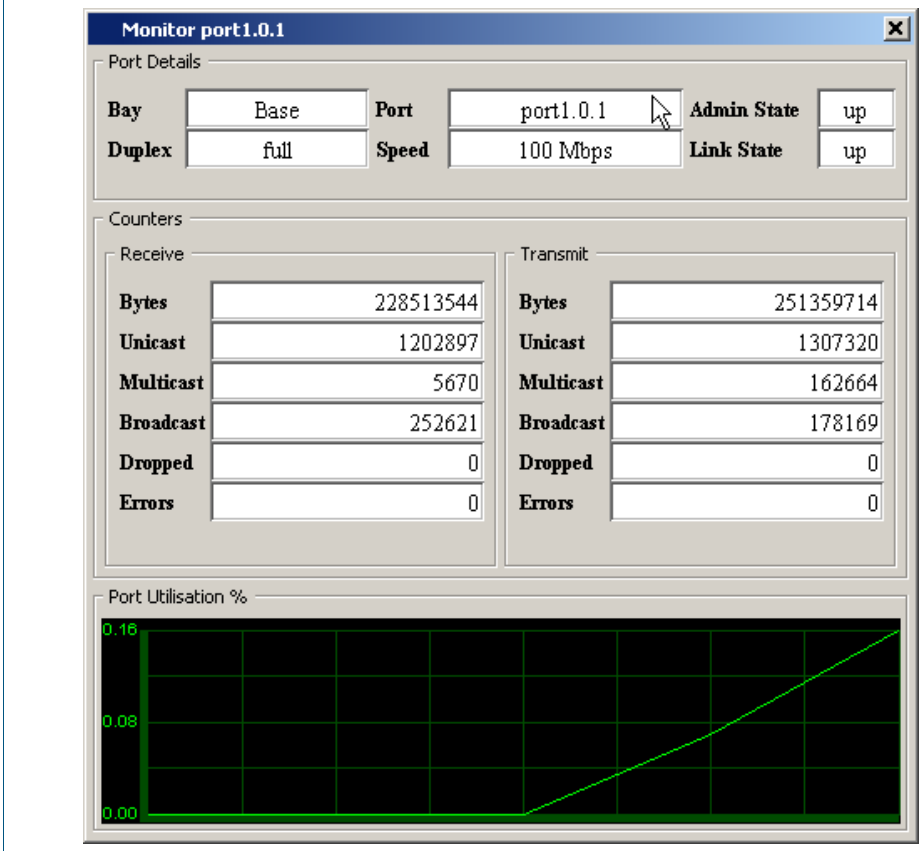


Switching > Ports > Monitor Port

The Switching > Ports > Monitor Port dialog allows you monitor port counters.

Configuration Dialog

Figure C-23: Example showing the **Switching > Ports > Monitor Port** dialog:



Description

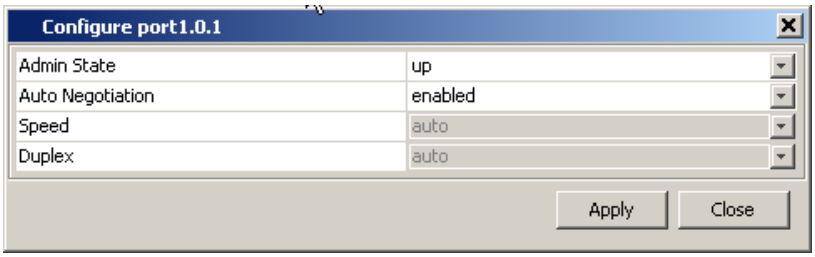
Label / Field / Button	Description
`Port Details`	Monitors the bay, port, duplex, speed, administrative state and link states for the selected port.
`Counters`	Monitors the counters for bytes received/transmitted, unicast packets received/transmitted, multicast packets received/transmitted, broadcast packets received/transmitted, dropped packets received/transmitted, and errors received/transmitted for the selected port.
`Port Utilisation%`	Monitors and graphs the usage percentage for the selected port.

Switching > Ports > Configure Port

The Switching > Ports > Configure Port dialog allows you configure Administrative State, Auto Negotiation, Speed and Duplex settings for the selected port.

Configuration Dialog

Figure C-24: Example showing the **Switching > Ports > Configure Port** dialog:



Description

Label / Field / Button	Description
`Admin State`	Select `up` or `down` from the drop down list in this dialog to specify the administrative state for the selected port.
`Auto Negotiation`	Select `disabled` or `enabled` from the drop down list in this dialog to specify auto negotiation for the selected port. Note that selecting `enabled` to enable `Auto Negotiation` will disable Speed and Duplex options, indicated by greyed out options.
`Speed`	Select `10 Mbps`, `100 Mbps`, `1000 Mbps`, `10 Gbps`, or `auto` from the drop down list in this dialog to specify the speed setting for the selected port. Note that the options for speed settings are only available if `Auto Negotiation` has been `disabled` for the selected port.
`Duplex`	Select `full`, `half`, or `auto` from the drop down list in this dialog to specify the duplex setting for the selected port. Note that the options for duplex settings are only available if `Auto Negotiation` has been `disabled` for the selected port.

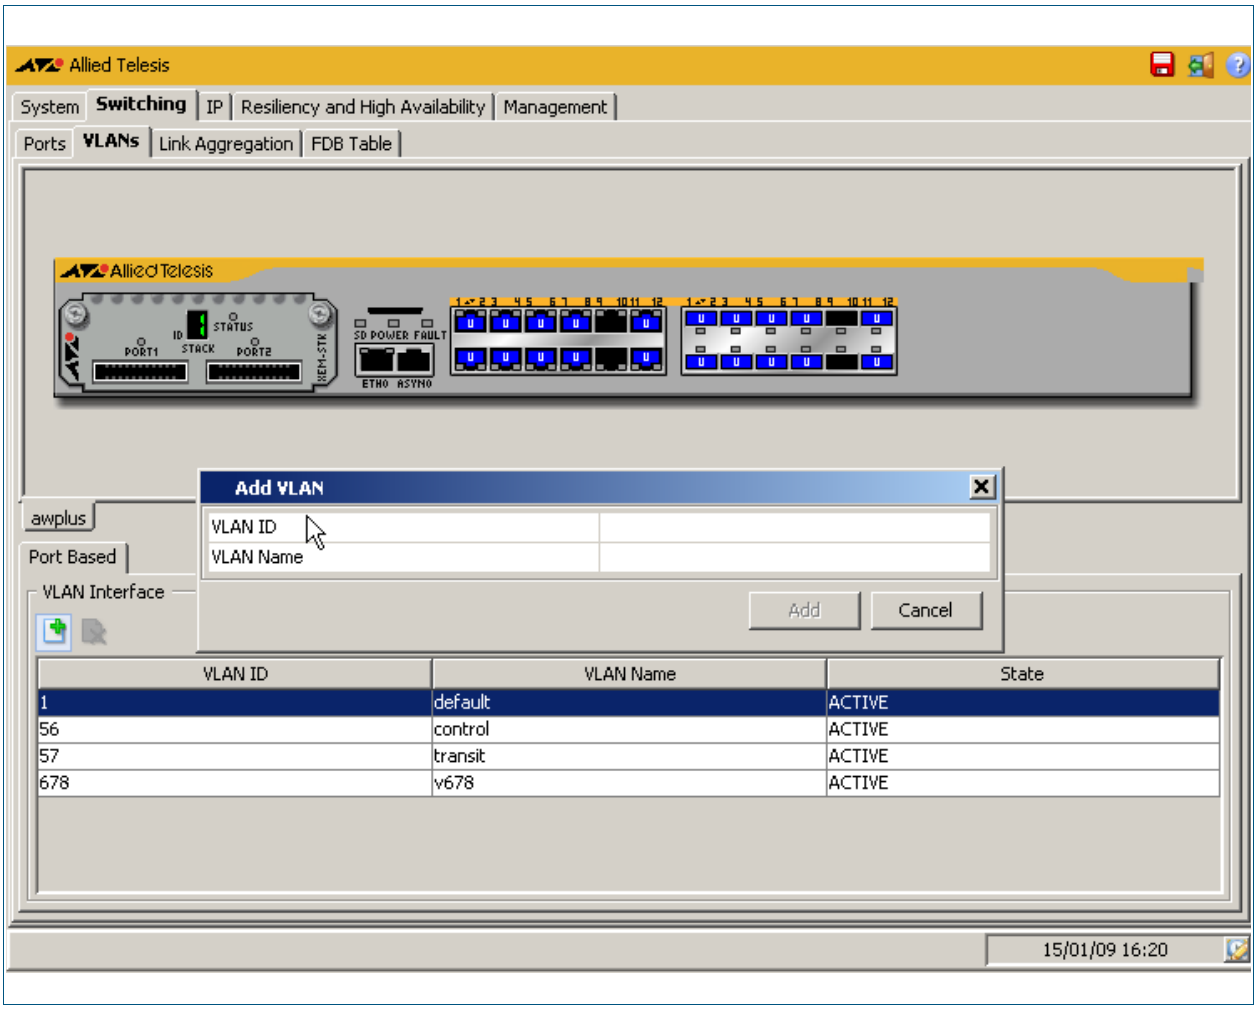
Switching > VLANs

The Switching > VLANs menu tab allows you to view, and configure Layer 2 properties:

- Right-clicking a port allows you to select a VLAN to be tagged or untagged for the port, or to remove a port from the VLAN.
- Define VLANs before assigning VLANs to ports on the front panel of the switch.
- Selecting the **+** icon (under the VLAN Interface label on the VLAN tab below the front panel illustration) allows you to add a VLAN by specifying the VLAN ID and VLAN Name.
- Selecting the **x** icon (under the VLAN Interface label below the front panel illustration) allows you to delete a VLAN (except for the default VLAN 1 that is assigned to all ports).

Note: For systems equipped and configured using VCStack there is a separate tab for each stack member with the system name displayed on each tab.

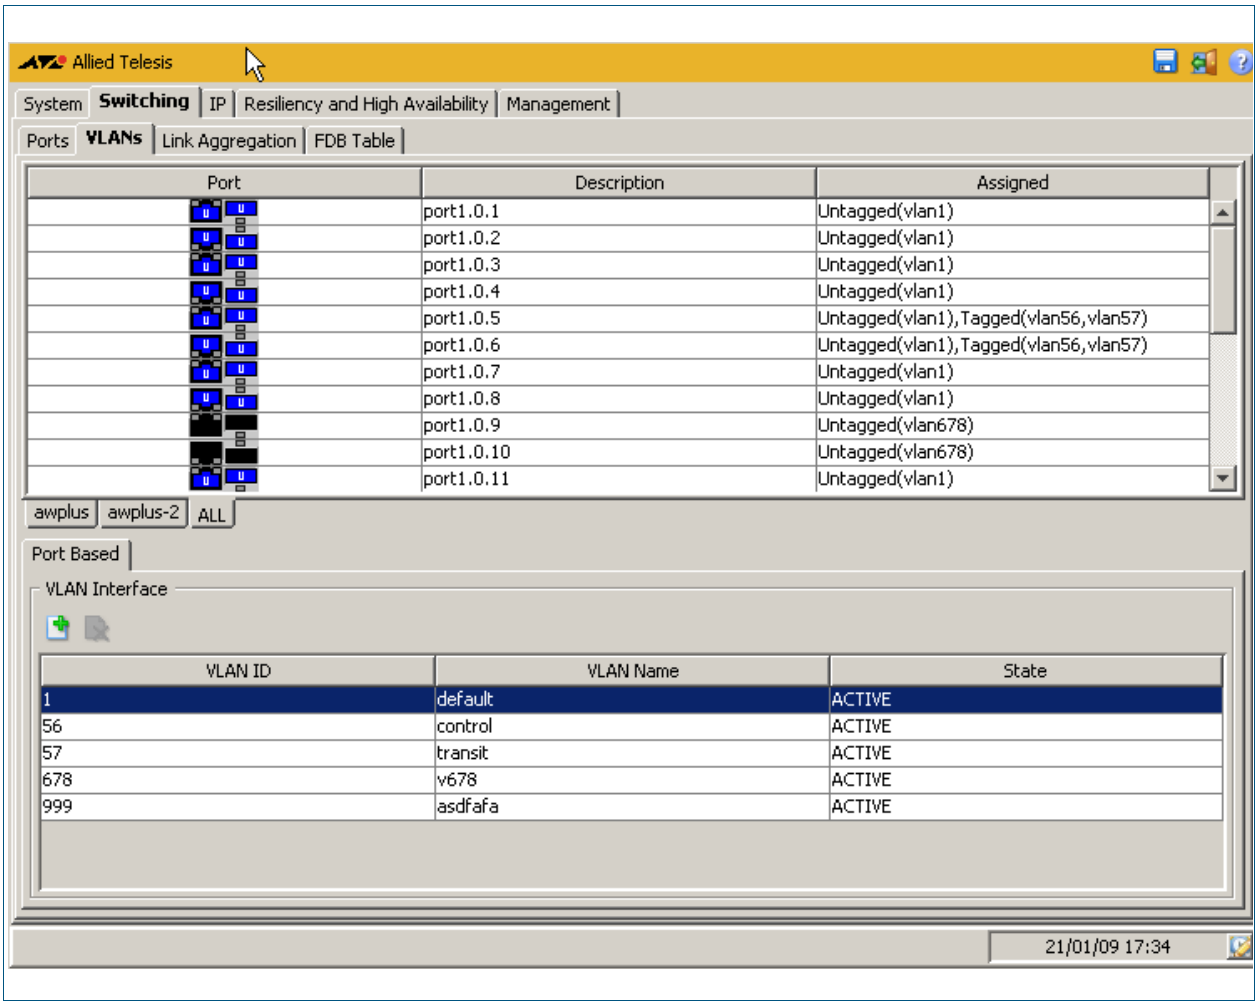
Menu Tab Figure C-25: Example showing the **Switching > VLANs** menu tab:



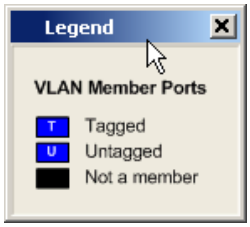
Description

Label / Field / Button	Description
`Port Based / VLAN ID`	The VID of the VLAN that is enabled or disabled in the range 1-4094.
`Port Based / VLAN Name`	The ASCII name of the VLAN with a maximum length of 32 characters.
`Port Based / State`	The state of the VLAN, either enabled ('ACTIVE' displayed) or disabled ('INACTIVE' displayed).

Menu Tab Figure C-26: Example showing the **Switching > VLANs > ALL** menu tab:



Legend Figure C-27: Example showing **Switching > VLANs > Legend**:

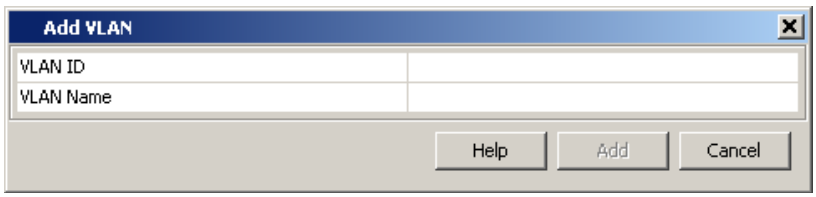


Switching > VLANs > Add VLAN

The Switching > VLANs > Add VLAN dialog allows you add a VLAN by specifying the VLAN ID and VLAN Name.

Configuration Dialog

Figure C-28: Example showing the **Switching > VLANs > Add VLAN** dialog:



Description

Label / Field / Button	Description
VLAN ID	Enter the VID of the VLAN that is enabled or disabled in the range <1-4094>.
VLAN Name	Enter the ASCII name of the VLAN with a maximum length of 32 characters.

Switching > Link Aggregation

The Switching > Link Aggregation menu tab allows you to view, and configure Layer 2 properties:

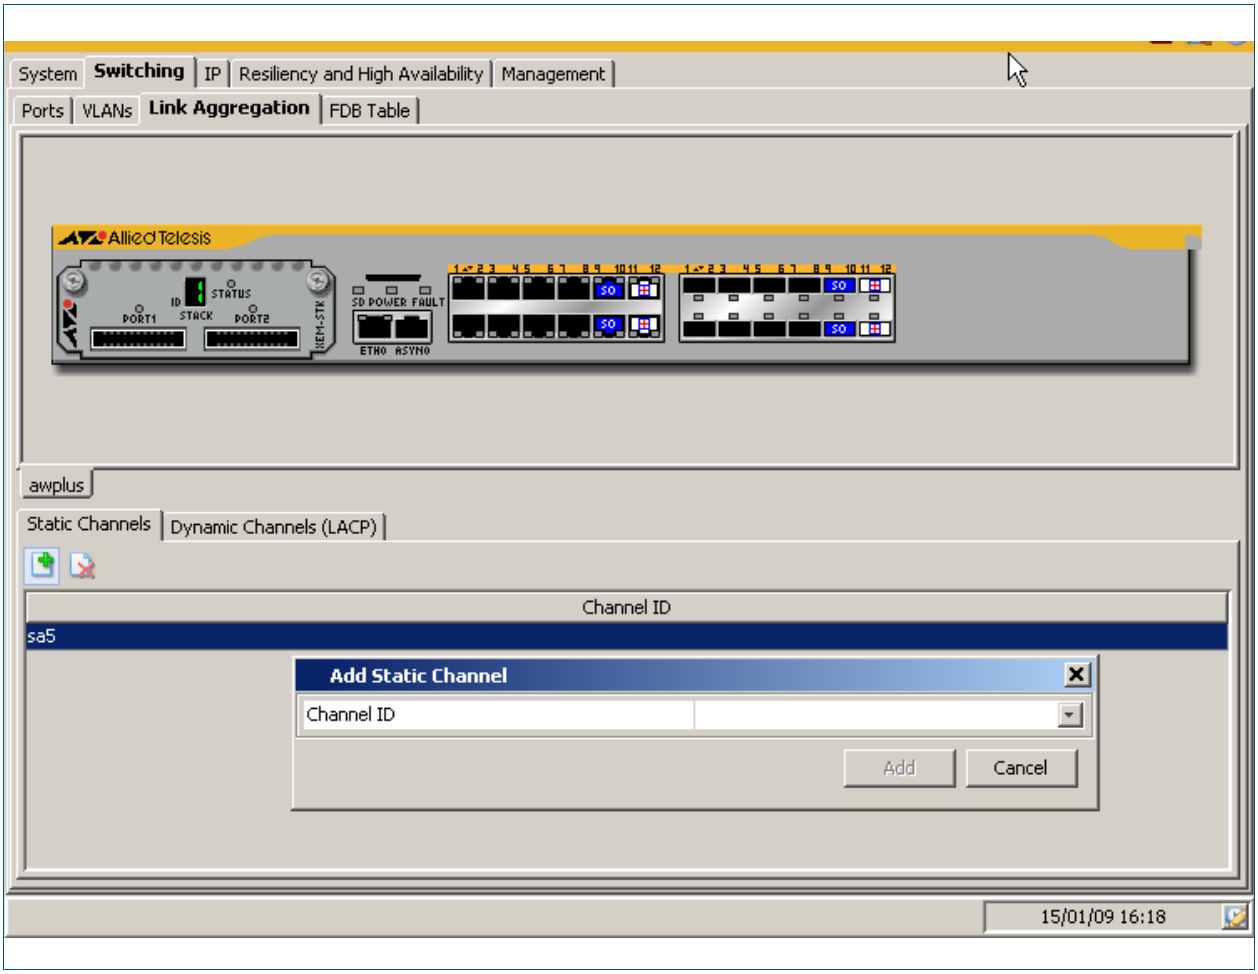
- Right-clicking a port allows you to select assign or remove the port to a Static Channel or a Dynamic Channel (LACP - Link Aggregation Control Protocol) group.
- Define Static Channel or Dynamic Channel (LACP) groups before assigning them to ports on the front panel of the switch.
- Selecting the + icon (located below the front panel illustration of your switch) allows you to add a Static Channel or Dynamic Channel (LACP) group by specifying the Channel ID.

Note: Up to 31 Static Channel groups and up to 99 Dynamic Channel (LACP) groups can be defined on a switch.

- Selecting the x icon (located below the front panel illustration of your switch) allows you to delete a Static Channel or Dynamic Channel (LACP) group.

Note: For systems equipped and configured using VCStack there is a separate tab for each stack member with the system name displayed on each tab.

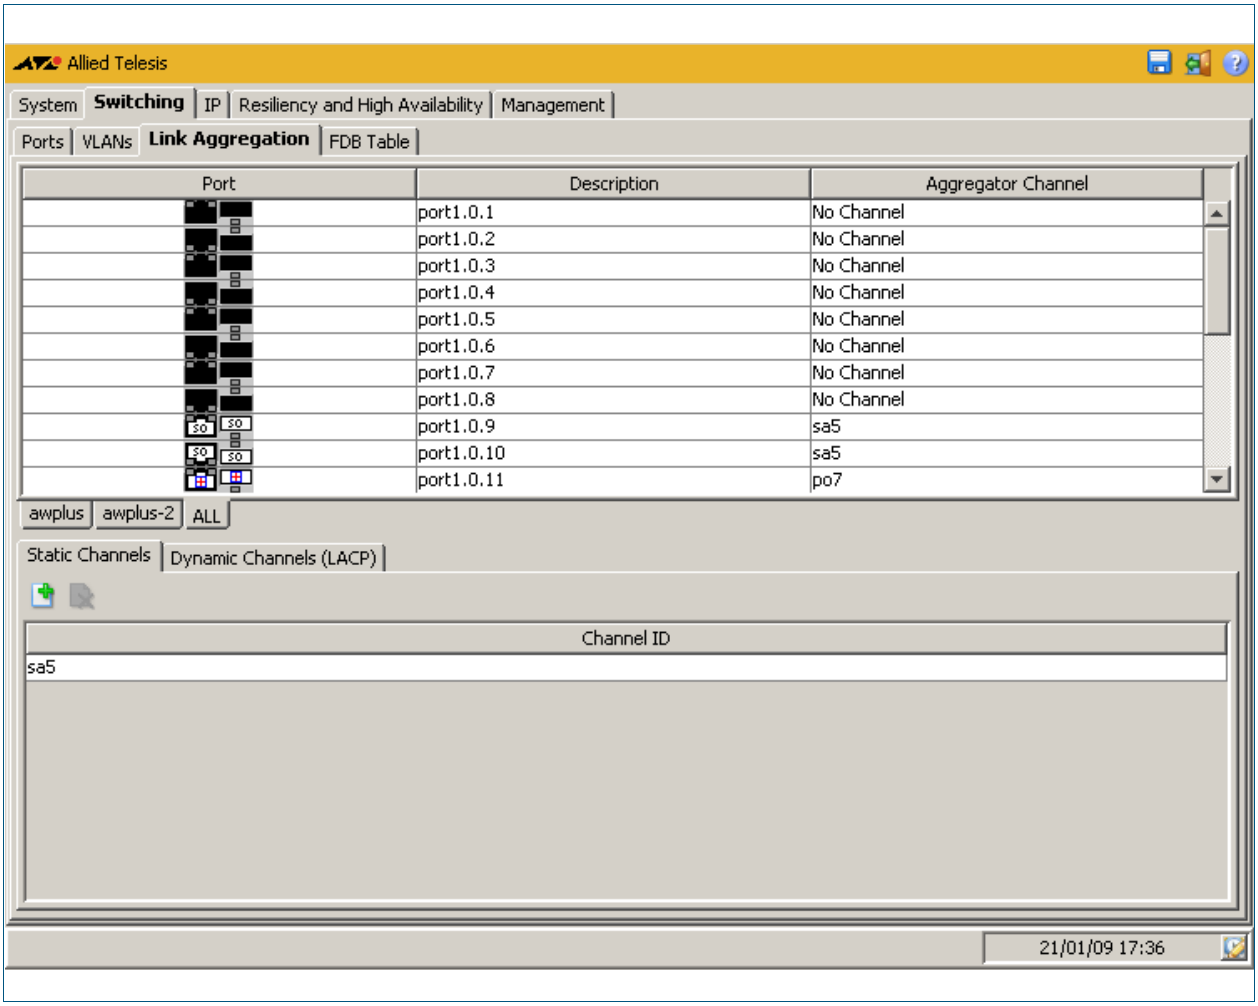
Menu Tab Figure C-29: Example showing the **Switching > Link Aggregation** menu tab:



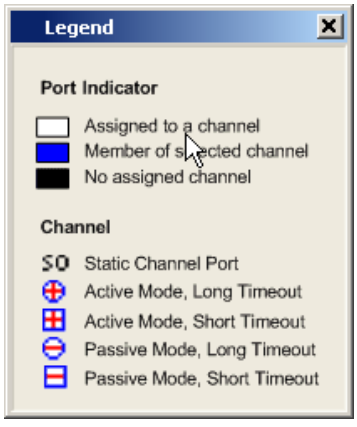
Description

Label / Field / Button	Description
`Static Channels`	Display or specify a static channel group number for an aggregated link. Up to 31 static channel groups can be created on the switch.
`Dynamic Channels (LACP)`	Display or specify a dynamic channel group number for an LACP link. Up to 99 dynamic channel groups can be created on the switch.

Menu Tab Figure C-30: Example showing the **Switching > Link Aggregation > ALL** menu tab:



Legend Figure C-31: Example showing **Switching > Link Aggregation > Legend**:

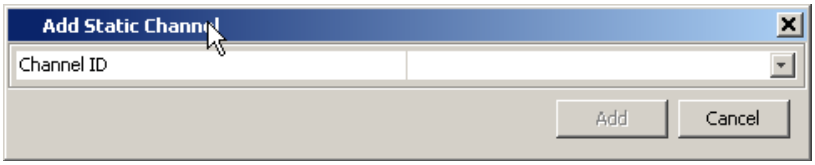


Switching > Link Aggregation > Add Static Channel

The Switching > Link Aggregation > Add Static Channel dialog allows you to assign the selected port to a Static Channel group.

Configuration Dialog

Figure C-32: Example showing the **Switching > Link Aggregation > Add Static Channel** dialog:



Description

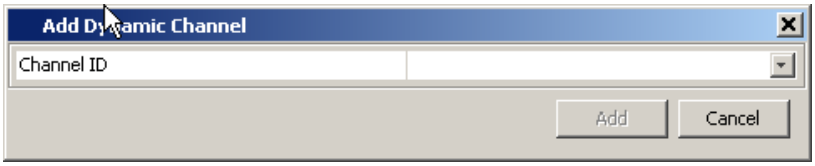
Label / Field / Button	Description
Channel ID	Specify a static channel group number for an interface. Up to 31 static channel groups can be created on the switch.

Switching > Link Aggregation > Add Dynamic Channel

The Switching > Link Aggregation > Add Dynamic Channel dialog allows you to assign the selected port to a Dynamic Channel (LACP) group.

Configuration Dialog

Figure C-33: Example showing **Switching > Link Aggregation > Add Dynamic Channel** dialog:



Description

Label / Field / Button	Description
Channel ID	Specify a dynamic (LACP) channel group number for an interface. Up to 99 dynamic (LACP) channel groups can be created on the switch.

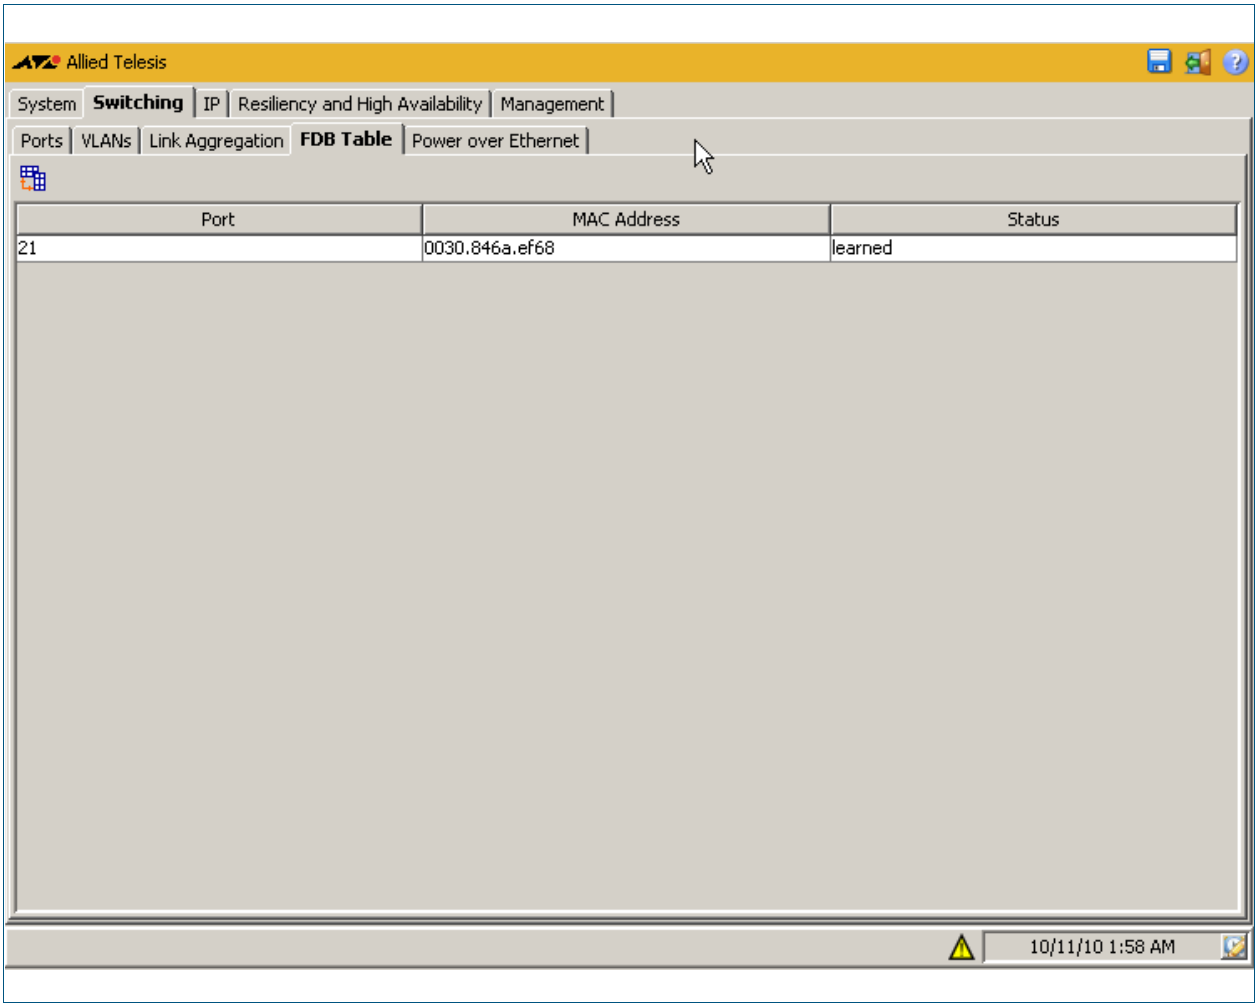
Switching > FDB Table

The Switching > FDB Table menu tab allows you to view the contents of the Layer 2 Forwarding Database Table.

You can change the FDB Table view to display horizontally or vertically by selecting the table view icon above the FDB Table.

You can also sort or rearrange the display of the FDB Table by Port, MAC Address, or Forwarding Status by selecting the relevant column or by dragging the relevant column respectively.

Menu Tab Figure C-34: Example showing the **Switching > FDB Table** menu tab:



Description

Label / Field / Button	Description
`FDB Table`	Displays the FDB (Forwarding Database) table for the switch that shows all the available ports, MAC addresses, and port status.

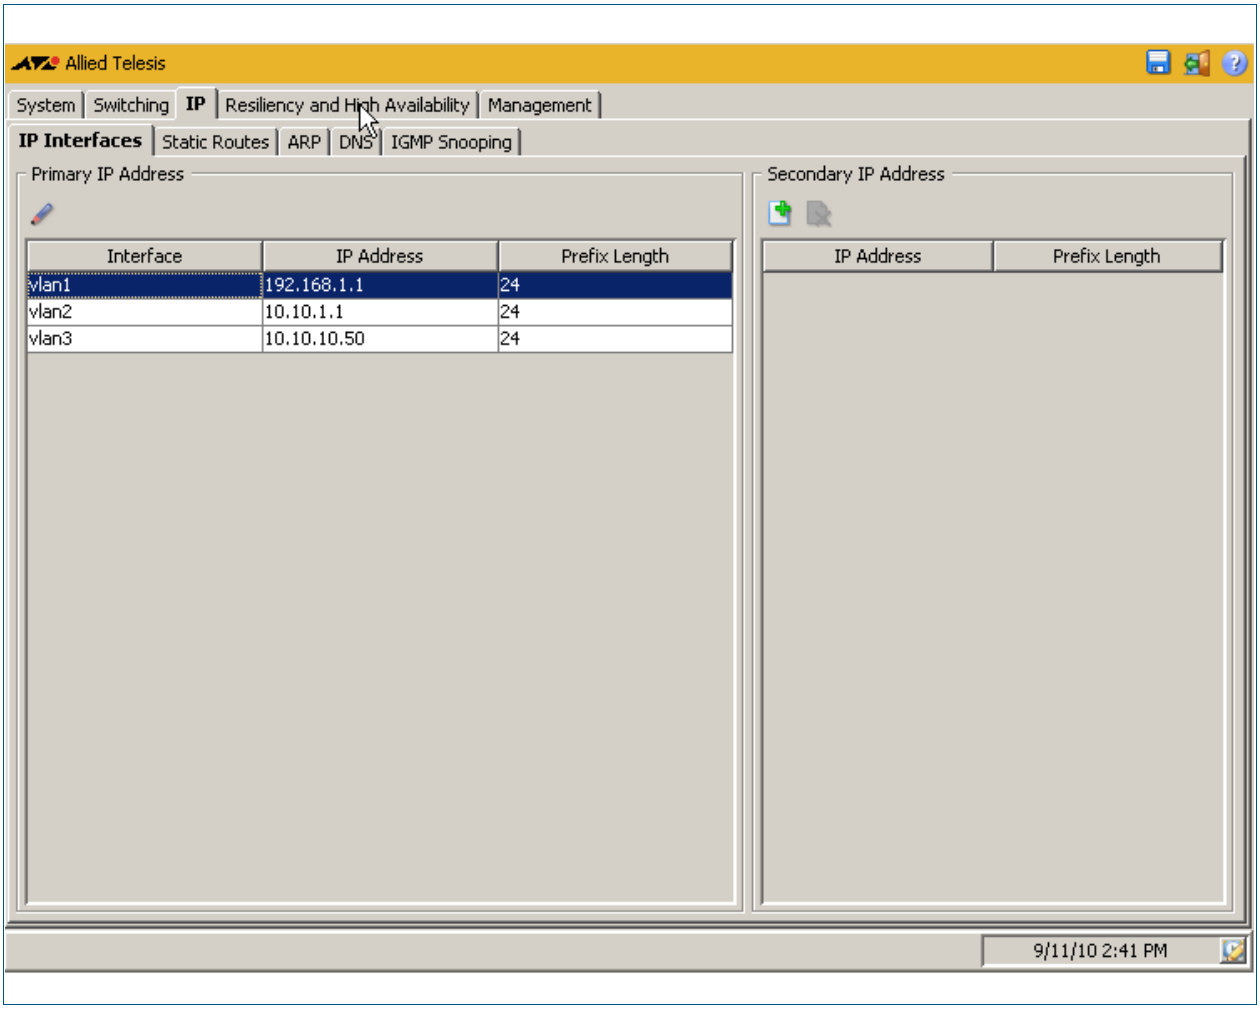
IP > IP Interfaces

The IP > IP Interfaces menu tab allows you to view and specify the Primary and Secondary IP Addresses for VLAN and management port interfaces.

Note: You may only define a Secondary IP Address for an interface after first defining its Primary IP Address.

- Select an interface then use the pen shaped icon under the Primary IP Address label to configure an IP address. You can delete an assigned Primary IP Address in the Configure Primary IP Address dialog as displayed after selecting the icon under Primary IP Address.
- Select an interface with a Primary IP Address already defined to configure a Secondary IP Address, using the **+** icon under the Secondary IP Address label.
- Remove a selected Secondary IP Address using the **x** icon under the Secondary IP Address label.

Menu Tab Figure C-35: Example showing the **IP > IP Interfaces** menu tab:



Description

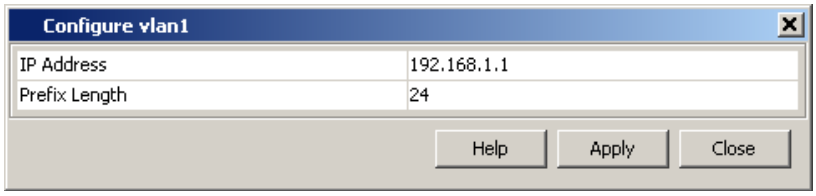
Label / Field / Button	Description
`Primary IP Address`	Displays and configures primary IP addressing for VLANs and management port interfaces that are defined on the switch and assigned to ports.
`Secondary IP Address`	Displays and configures secondary IP addressing for VLANs and management port interfaces that are defined on the switch and assigned to ports.

IP > IP Interfaces > Configure Primary IP Address

The IP > IP Interfaces > Configure Primary IP Address dialog allows you to configure a primary address with an IP address and a prefix length for the selected interface.

Configuration Dialog

Figure C-36: Example showing the **IP > IP Interfaces > Configure Primary IP Address** dialog:



Description

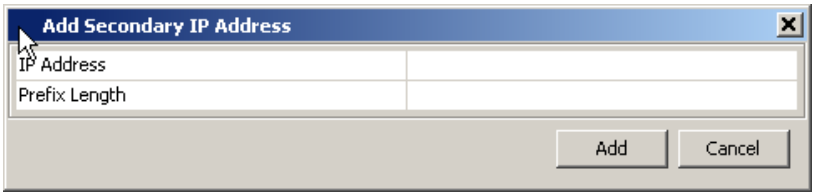
Label / Field / Button	Description
`IP Address`	Enter or remove an IPv4 Address in dotted decimal notation (i.e. A.B.C.D).
`Prefix Length`	Enter the Prefix for the IPv4 Address with the integer as used for slash notation (i.e. 24 instead of /24), not dotted decimal notation (i.e. 255.255.255.0).

IP > IP Interfaces > Add Secondary IP Address

The IP > IP Interfaces > Add Secondary IP Address dialog allows you to add a secondary address with an IP address and a prefix length for the selected interface (only if the selected interface already has a primary address configured).

Configuration Dialog

Figure C-37: Example showing the **IP > IP Interfaces > Add Secondary IP Address** dialog:



Description

Label / Field / Button	Description
`IP Address`	Enter an IPv4 Address in dotted decimal notation (i.e. `A.B.C.D`).
`Prefix Length`	Enter the Prefix for the IPv4 Address with the integer as used for slash notation (i.e. `24` instead of `/24`), not dotted decimal notation (i.e. `255.255.255.0`).

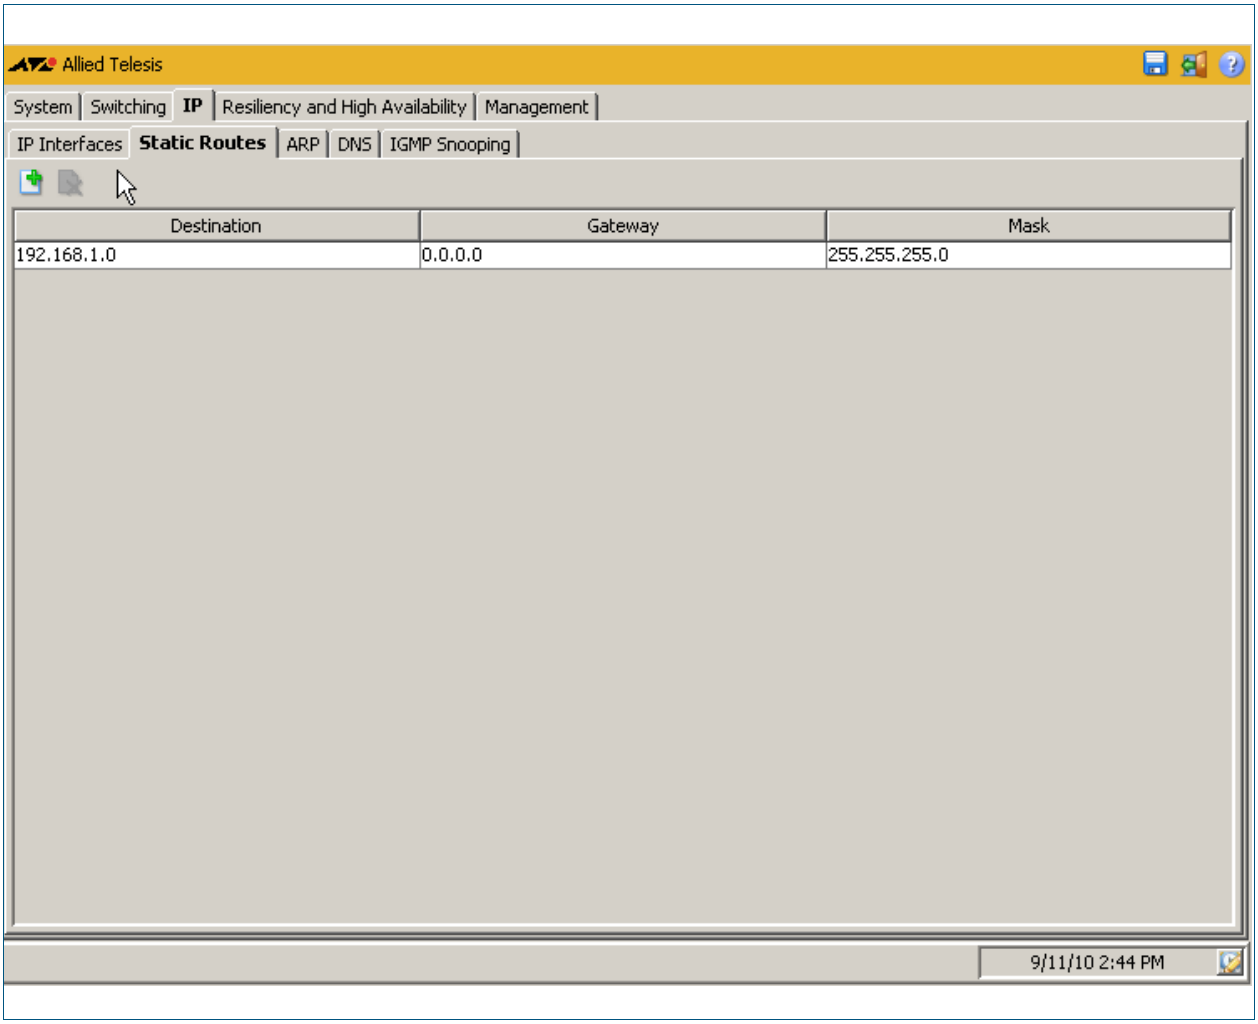
IP > Static Routes

The IP > Static Routes menu tab allows you to view, add, and delete static IP routes configured on the switch. Static routes are specified using destination IP addresses, masks, and gateways.

You can also sort or rearrange the display of the Static Routes by Destination, Gateway, or Mask by selecting the relevant column or by dragging the relevant column respectively.

- Selecting the + icon allows you to define a Static Route specifying destination and gateway IPv4 addresses with a dotted decimal format subnet mask.
- Selecting the x icon allows you to delete a defined Static Route.

Menu Tab Figure C-38: Example showing the **IP > Static Routes** menu tab:



Description

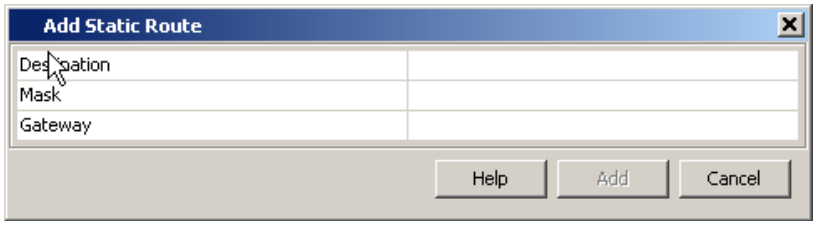
Label / Field / Button	Description
`Static Routes / Destination`	The IPv4 address of the destination subnet address.
`Static Routes / Gateway`	The IPv4 address of the gateway device.
`Static Routes / Mask`	The subnet mask in dotted decimal notation (for example, 255.255.255.0 instead of the slash notation /24).

IP > Static Routes > Add Static Route

The IP > Static Routes > Add Static Route dialog allows you to add a static IP routes on the switch. Static routes are specified using destination IP addresses, masks, and gateways.

Configuration Dialog

Figure C-39: Example showing the **IP > Static Routes > Add Static Route** dialog:



Description

Label / Field / Button	Description
`Destination`	Enter the IPv4 address of the destination subnet address.
`Mask`	Enter the subnet mask in dotted decimal notation (for example, 255.255.255.0 instead of the slash notation /24).
`Gateway`	Enter the IPv4 address of the gateway device.

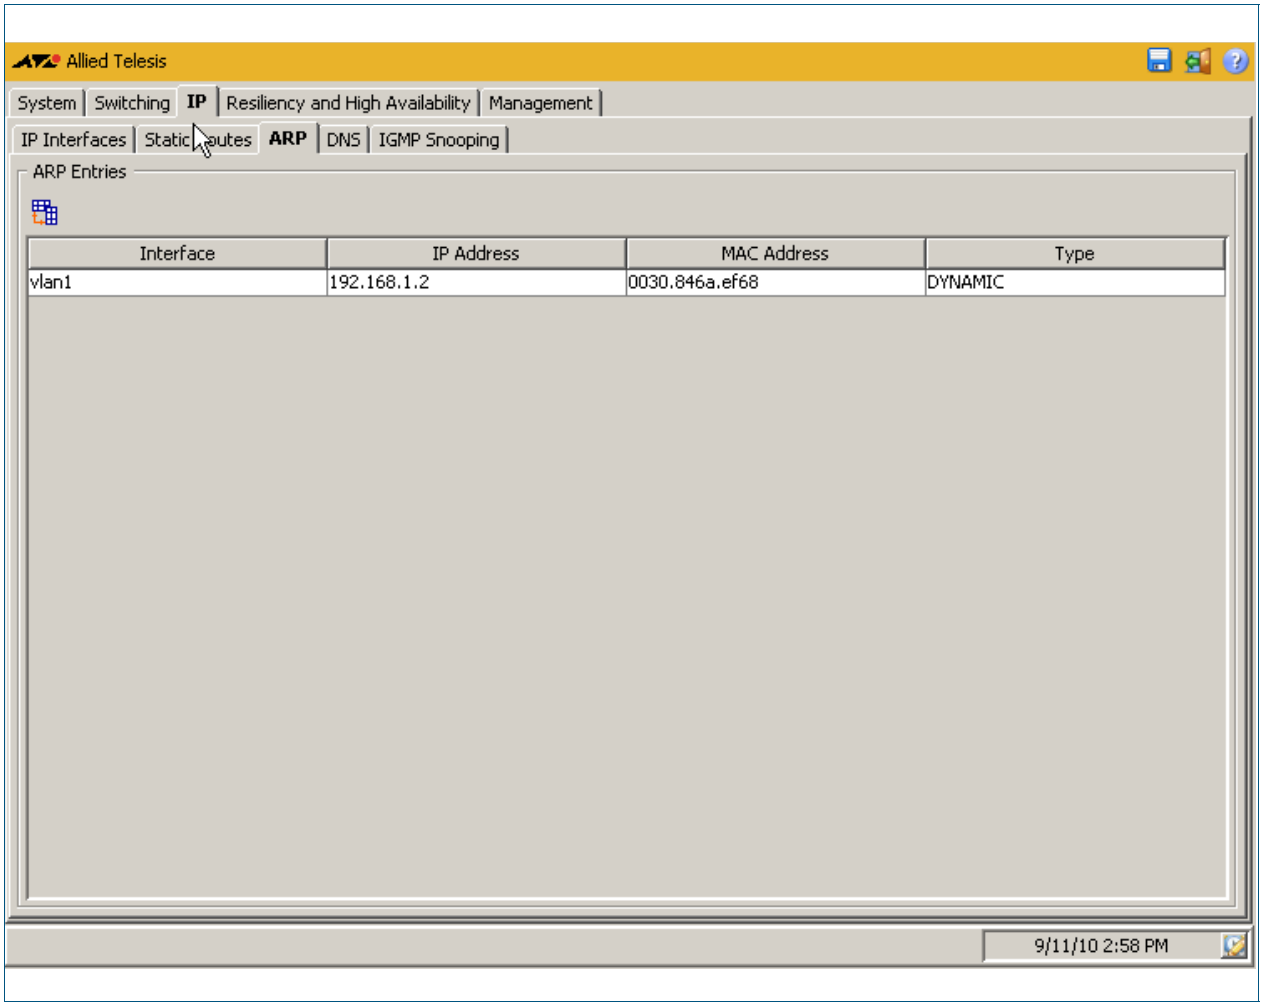
IP > ARP

The IP > ARP menu tab allows you to view the contents of the ARP (Address Resolution Protocol) Table.

You can change the ARP Entries view to display horizontally or vertically by selecting the table view icon above the ARP Entries.

You can also sort or rearrange the display of the ARP Entries by Interface, IP Address, MAC Address, or Type by selecting the relevant column or by dragging the relevant column respectively.

Menu Tab Figure C-40: Example showing the **IP > ARP** menu tab:



Description

Label / Field / Button	Description
`ARP Entries / Interface`	Interface over which the switch is accessed, usually a VLAN.
`ARP Entries / IP Address`	IP address of the network device this ARP entry maps to.

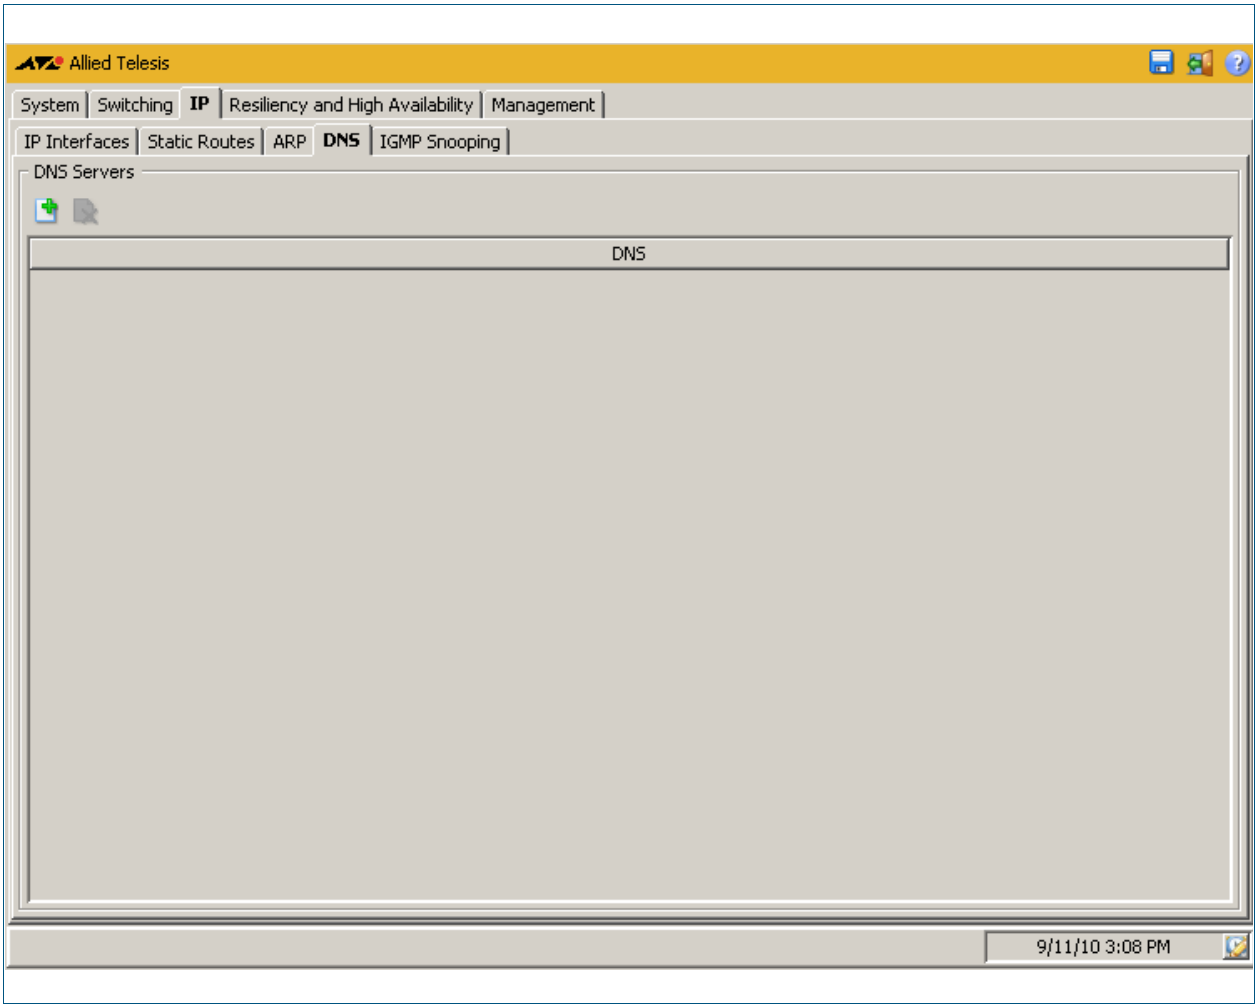
Label / Field / Button	Description(cont.)
ARP Entries / MAC Address	Hardware address of the switch in hexadecimal format HHHH.HHHH.HHHH.
ARP Entries / Type	Indicates whether the ARP entry is a Static or Dynamic ARP entry. Static ARP entries are added and dynamic ARP entries are learned.

IP > DNS

The IP > DNS menu tab allows you to display and configure DNS (Domain Name System) server entries for the switch.

- Selecting the + icon allows you to define a DNS Server specifying the IPv4 address.
- Selecting the x icon allows you to delete a defined DNS Server.

Figure C-41: Example showing the **IP > DNS** menu tab:



Description

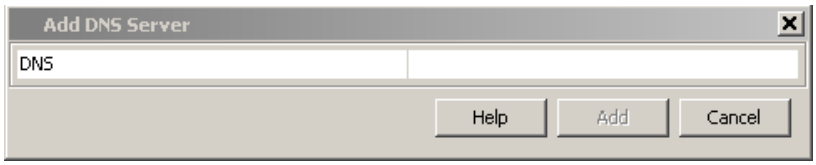
Label / Field / Button	Description
DNS	DNS Server IPv4 address.

IP > DNS > Add DNS Server

The IP > DNS > Add DNS Server dialog allows you to add DNS (Domain Name System) server entries for the switch.

Configuration Dialog

Figure C-42: Example showing the **IP > DNS > Add DNS Server** dialog:



Description

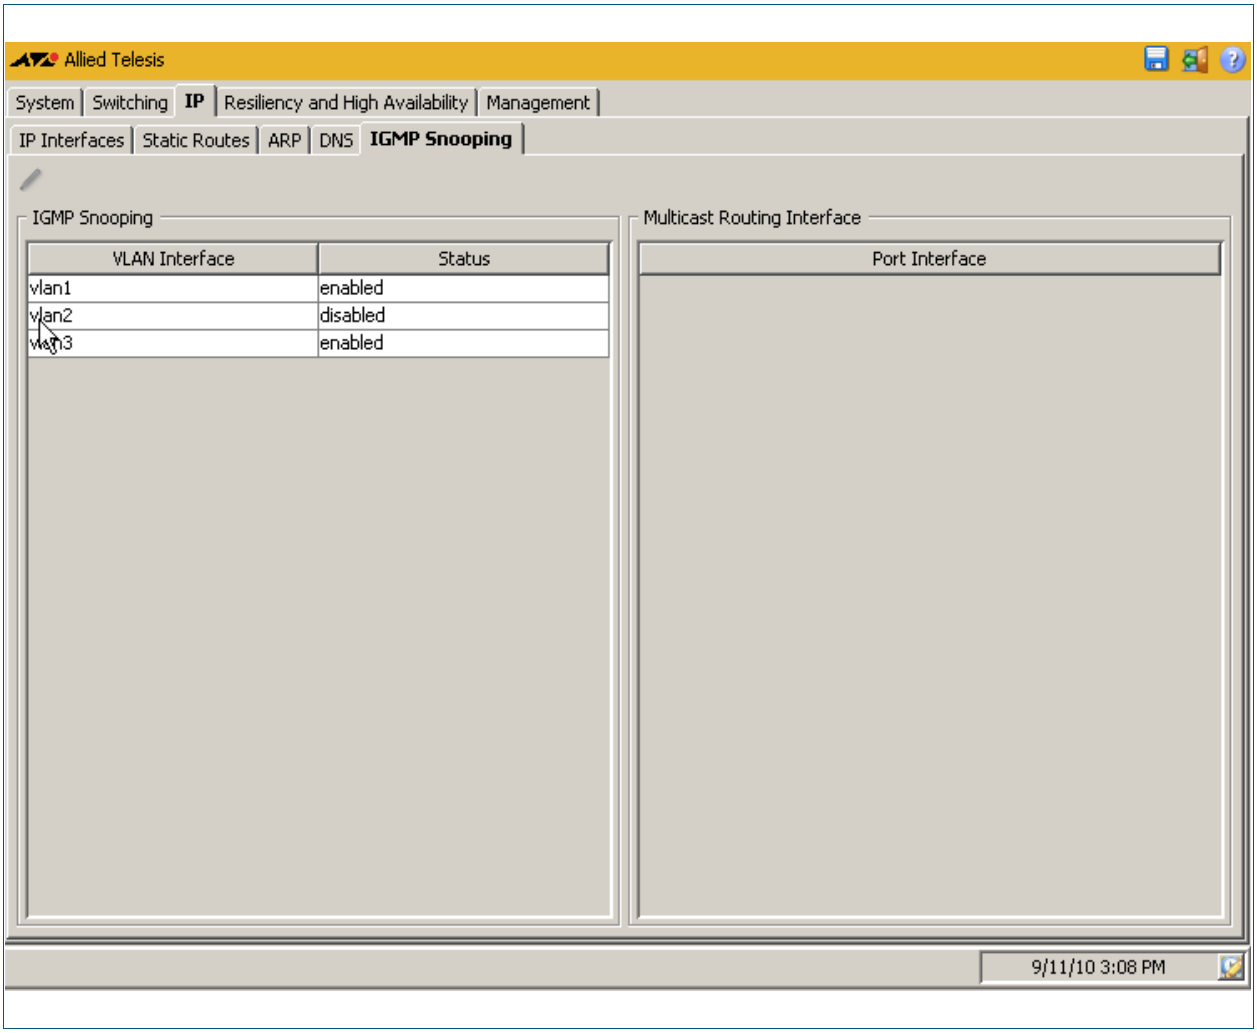
Label / Field / Button	Description
DNS	Enter an IPv4 address in dotted decimal notation (i.e. A.B.C.D) for the DNS (Domain Name System) Server you want to specify.

IP > IGMP Snooping

Menu Tab The IP > IGMP Snooping menu tab displays basic IGMP Snooping and Multicast Routing Interface information.

You can also configure IGMP Snooping on individual ports by selecting the VLAN interface that the port is a member of then clicking on the pen shaped icon to display the Configure IGMP Snooping dialog, where you can enable or disable IGMP snooping on desired ports.

Menu Tab Figure C-43: Example showing the **IP > IGMP Snooping** menu tab:



Description

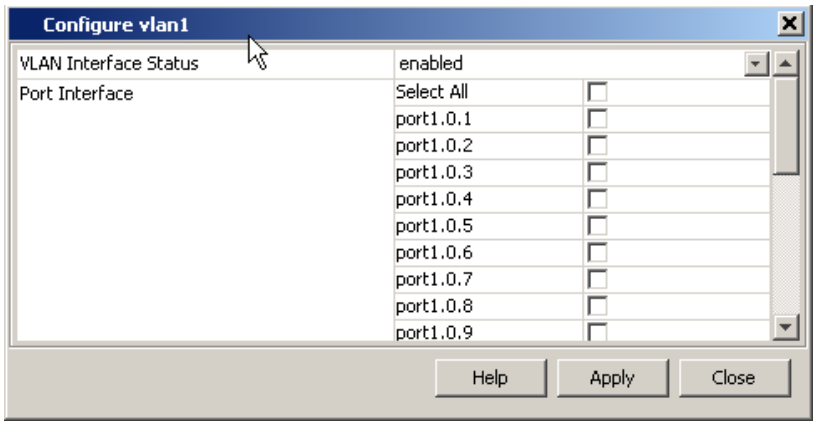
Label / Field / Button	Description
IGMP Snooping / IGMP Snooping	Displays and configures IGMP Snooping for a specified VLAN interface.
IGMP Snooping / Multicast Routing Interface	Displays and configures the specified port in the VLAN as a multicast router for IGMP Snooping.

IP > IGMP Snooping > Configure Interface

The IP > IGMP Snooping > Configure Interface dialog allows you to configure IGMP Snooping on individual ports. First select the VLAN interface that the port is a member of then enable or disable IGMP snooping on desired ports from this dialog.

Configuration Dialog

Figure C-44: Example showing the **IP > IGMP Snooping > Configure Interface** dialog:



Description

Label / Field / Button	Description
`VLAN Interface Status`	Displays whether the selected VLAN is enabled or disabled.
`Port Interface`	Select the check box for a given port to allocate it to the VLAN.

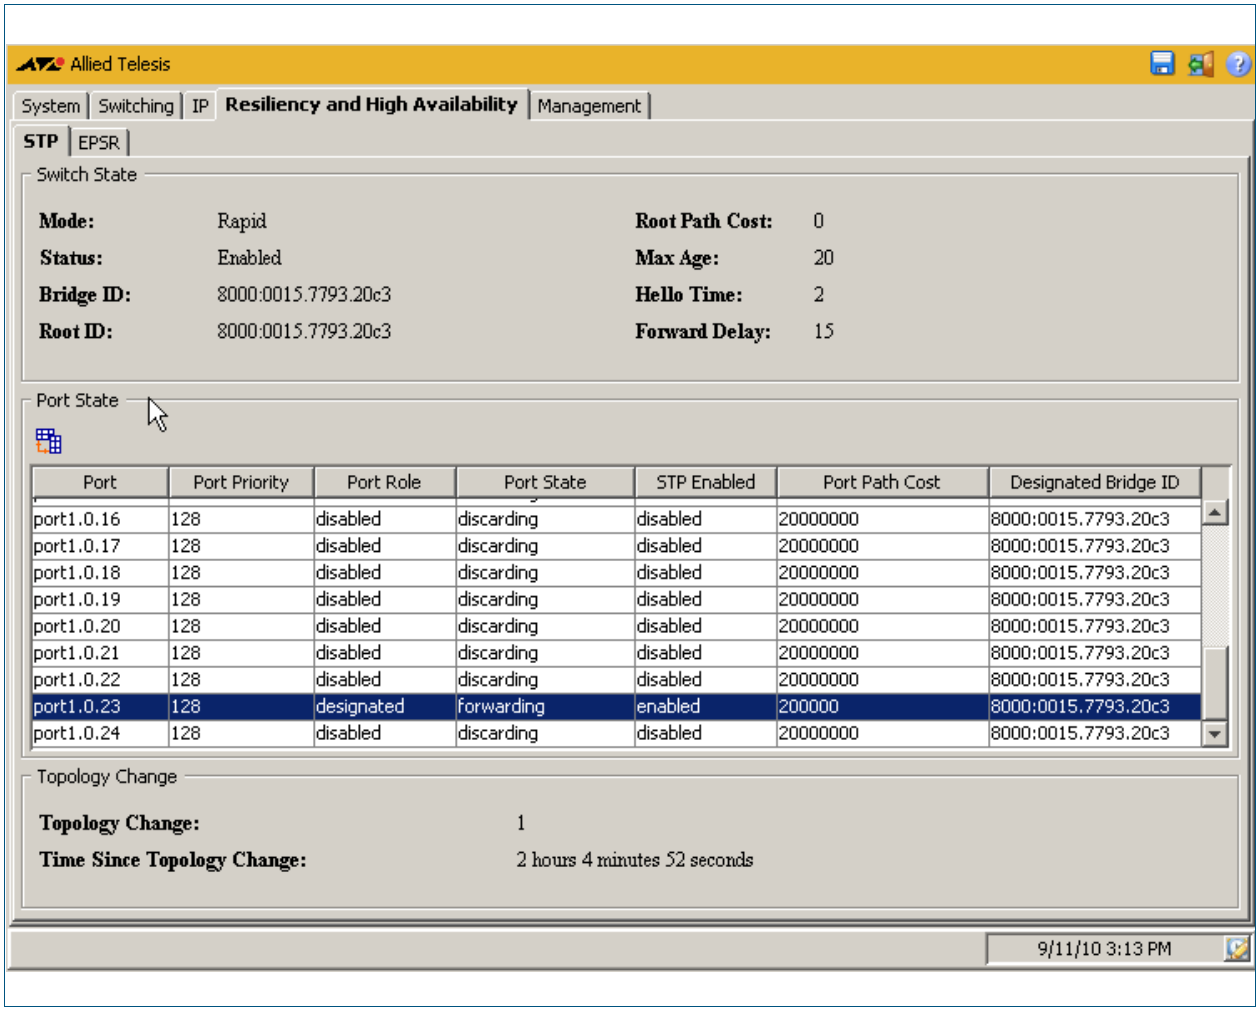
Resiliency and High Availability > STP

The Resiliency and High Availability > STP menu tab allows you to view the configuration and status of spanning tree data: for the switch as a whole and for each port.

You can also sort or rearrange the display of the Port State table by Port, Port Priority, Port State, Port Role, STP Enabled, Port Path Cost, or Designated Bridge ID by selecting the relevant column or by dragging the relevant column respectively.

Note: STP is not configurable through the GUI. Refer to the relevant STP chapters in the AlliedWare Plus™ Software Reference to configure STP using the CLI instead.

Menu Tab Figure C-45: Example showing the **Resiliency and High Availability > STP** menu tab:



Description: Switch State

Label / Field / Button	Description
Switch State / Mode	Spanning Tree Mode displayed: STP (Spanning Tree Protocol), Rapid (Rapid Spanning Tree Protocol - RSTP), or Multiple (Multiple Spanning Tree Protocol - MSTP).
Switch State / Status	Status of the Spanning Tree Mode: enabled or disabled.
Switch State / Bridge ID	Bridge ID, comprising the port priority followed by its MAC address.
Switch State / Root ID	Root Bridge ID, comprising the root priority followed by its MAC address.
Switch State / Root Path Cost	Sum of the costs for each path between the bridge port and the root bridge.
Switch State / Max Age	Time in seconds that the dynamic spanning tree configuration information is stored in the switch before it is discarded.
Switch State / Hello Time	Time in seconds between the transmission of switch spanning tree configuration information, when the switch is the Root Bridge of the spanning tree or is trying to become the Root Bridge.
Switch State / Forward Delay	Time in seconds to control how fast a port changes its spanning tree state when moving towards the forwarding state. This value is used only when the switch is acting as the root bridge. Note that Forward Delay, Max Age, and Hello Time are interrelated.

Description: Port State

Label / Field / Button	Description
Port State / Port	Switch port number in the format 'portX.Y.Z' where X is the switch, Y is the XEM, and Z is the individual switch port number.
Port State / Port Priority	The lower the port priority, the higher the likelihood of the port becoming part of the active network topology.
Port State / Port Role	Displays the port role as configured in the CLI with 'spanning-tree' commands, and shows either 'rootport', 'backup', 'disabled' or 'designated' port roles.
Port State / Port State	Displays the spanning tree state for the port as configured in the CLI with 'spanning-tree' commands. Indicates spanning tree states of: disabled, blocking, listening, learning, and forwarding.
Port State / STP Enabled	Displays whether spanning-tree is enabled or disabled. Spanning tree is enabled by default.
Port State / Port Path Cost	The cost of a path for the port that determines the total cost path. The lower the total cost, the higher the priority of the path.
Port State / Designated Bridge ID	The unique parent for each bridge that connects it to the next LAN on the path towards the root bridge.

Description: Topology Change

Label / Field / Button	Description
`Topology Change / Topology Change`	The number of STP Topology Changes that have occurred since the switch was rebooted.
`Topology Change / Time Since Topology Change`	The time in hours and seconds since the previous STP Topology Change occurred.

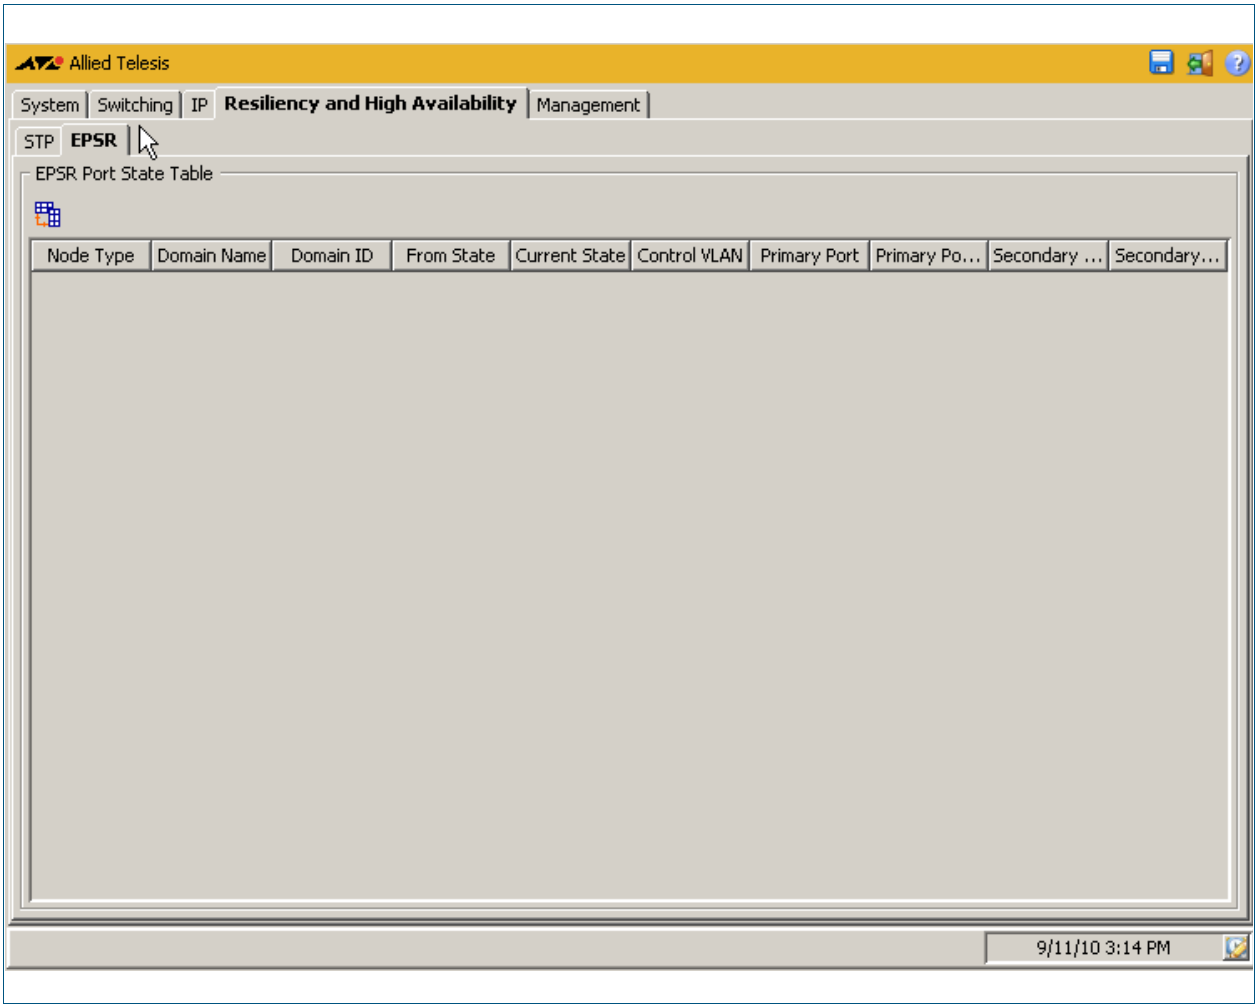
Resiliency and High Availability > EPSR

The Resiliency and High Availability > EPSR menu tab allows you to display the properties and status of any EPSR domains configured on the switch.

You can also sort or rearrange the display of the EPSR Port State table by Node Type, Domain Name, Domain ID, From State, Current State, Control VLAN, Primary Port, Primary Port Status, Secondary Port, or Secondary Port Status by selecting the relevant column or by dragging the relevant column respectively.

Note: EPSR is not configurable through the GUI. Refer to the relevant EPSR chapters in the AlliedWare Plus™ Software Reference to configure EPSR using the CLI instead.

Menu Tab Figure C-46: Example showing the **Resiliency and High Availability > EPSR** menu tab:



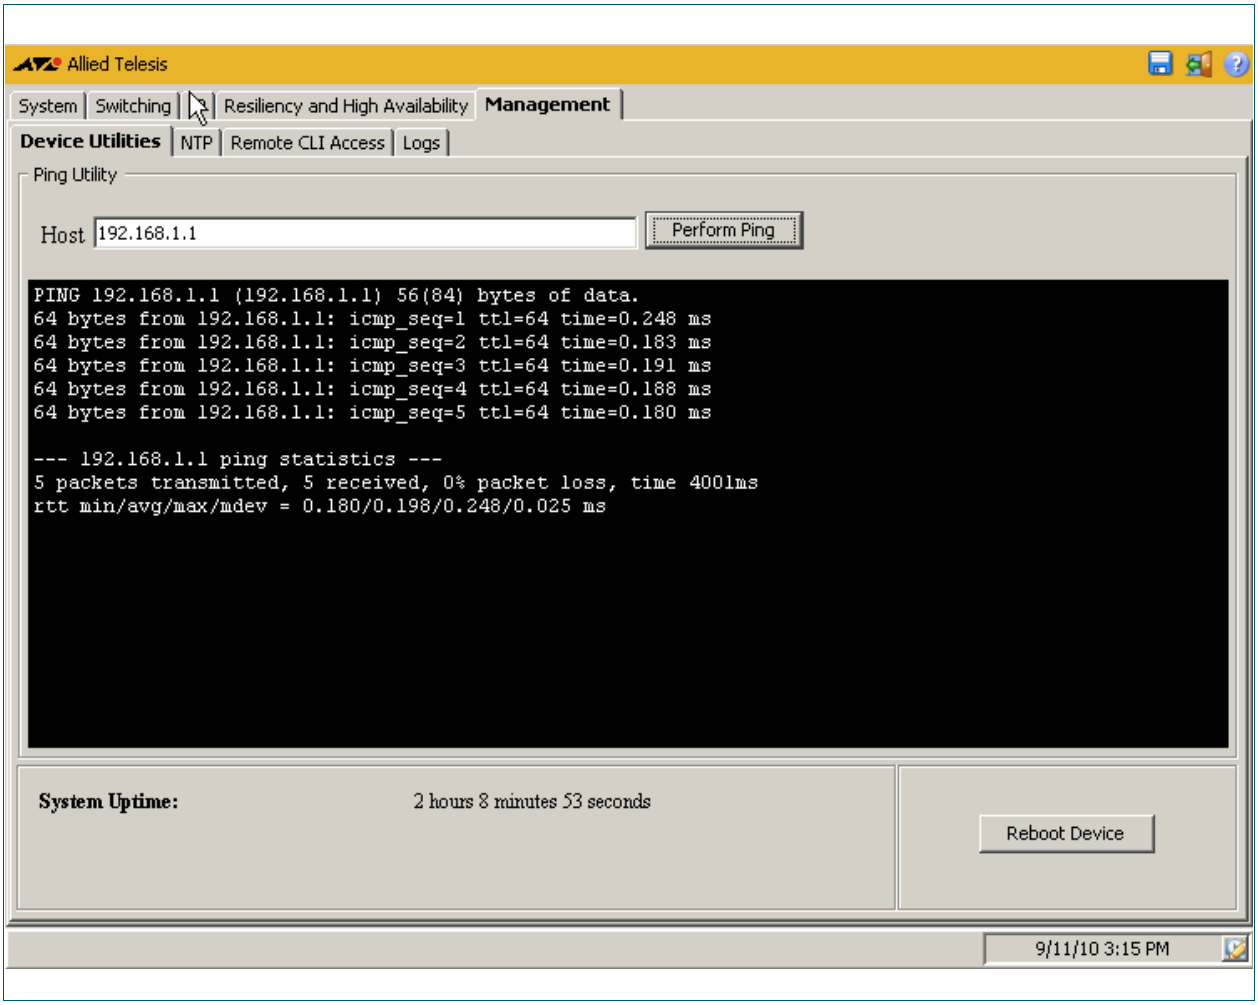
Description

Label / Field / Button	Description
EPSR Port State Table / Node Type	Displays master or transit node as configured in the CLI with the 'epsr mode' command.
EPSR Port State Table / Domain Name	Displays the domain name. A set of instances across a ring is called a domain.
EPSR Port State Table / Domain ID	Displays the assigned domain number for the domain name.
EPSR Port State Table / From State	Displays the From EPSR state as configured in the CLI with the 'epsr state' commands.
EPSR Port State Table / Current State	Displays the Current EPSR state as configured in the CLI with the 'epsr state' commands.
EPSR Port State Table / Control VLAN	Displays the control VLAN as configured in the CLI with the 'epsr mode controlvlan' command.
EPSR Port State Table / Primary Port	Displays the master node primary port interface name as configured in the CLI with the 'epsr mode primaryport' command.
EPSR Port State Table / Primary Port Status	Displays the master node primary port interface status: up or down.
EPSR Port State Table / Secondary Port	Displays the assigned secondary port interface name.
EPSR Port State Table / Secondary Port Status	Displays the assigned secondary port interface status: up or down.

Management > Device Utilities

The Management > Device Utilities menu tab allows you to perform pings and reboot the switch from the GUI.

Menu Tab Figure C-47: Example showing the **Management > Device Utilities** menu tab:



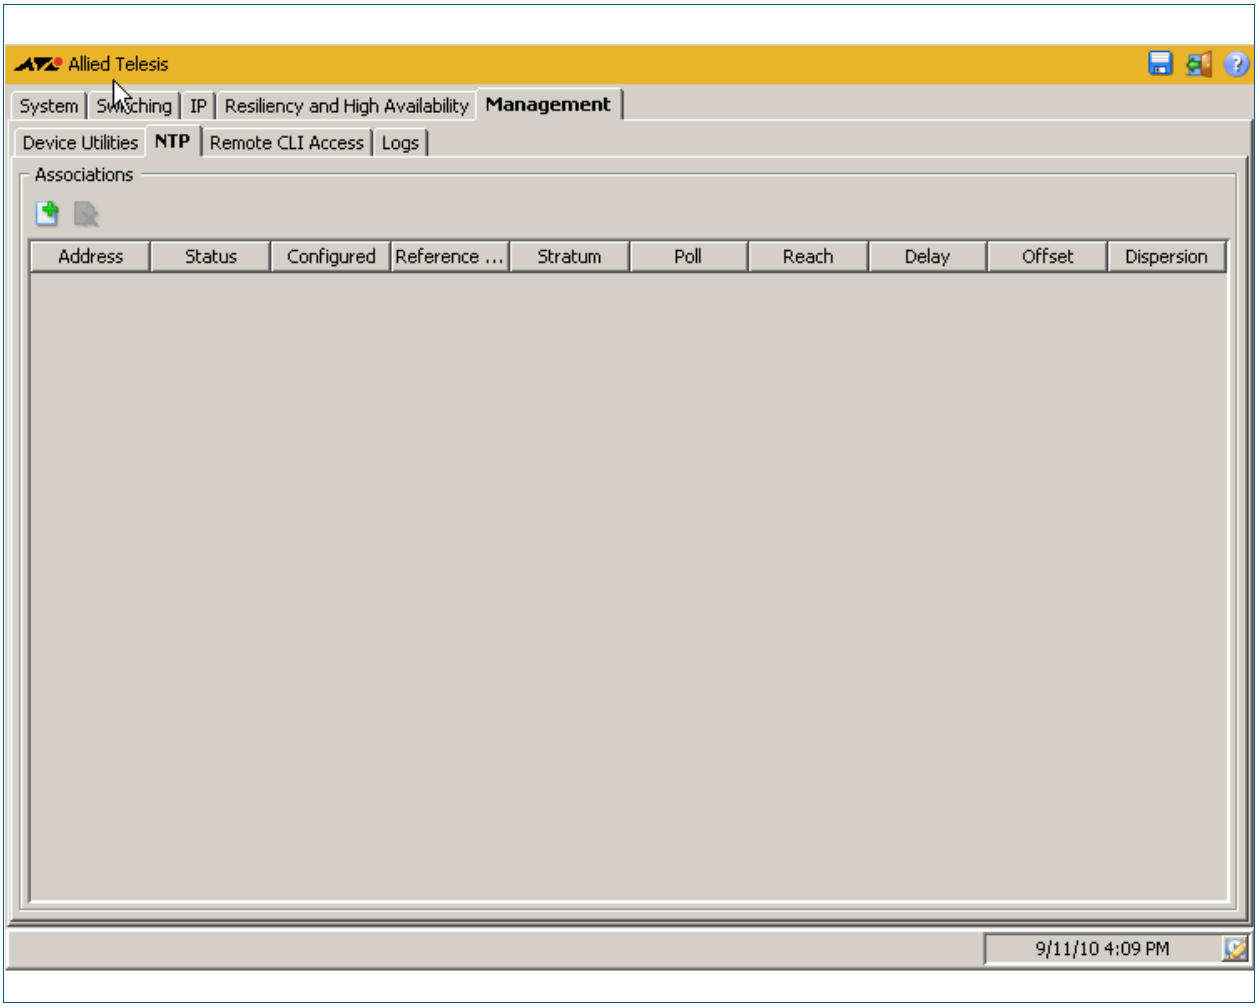
Description

Label / Field / Button	Description
`Ping Utility / Host`	Enter the IPv4 address or the URL that you want to ping in this field.
`Ping Utility / Perform Ping`	Select this button to ping the IPv4 address or URL that you entered in the Host field.
`System Uptime`	Displays the elapsed time since the last reboot in hours, minutes, and seconds.
`Reboot Device`	Select this button to reboot your switch. You will need to login to the GUI again after you reboot your switch. Rebooting closes all Telnet / SSH / SNMP sessions on your switch.

Management > NTP

The Management > NTP menu tab allows you to display and configure Network Time Protocol (NTP) peer configurations on the switch.

Menu Tab Figure C-48: Example showing the **Management > NTP** menu tab:



Description

Label / Field / Button	Description
`Associations / Address`	The NTP peer or NTP server IPv4 address.
`Associations / Status`	Indicates association status, and displays 'master(synced)'. 'master(unsynced)', 'selected', 'candidate', 'configured', or 'unknown'.
`Associations / Configured`	Indicates if the association is configured or not, and displays 'configured' or 'dynamic'.
`Associations / Reference Clock`	The IPv4 address for the reference clock.

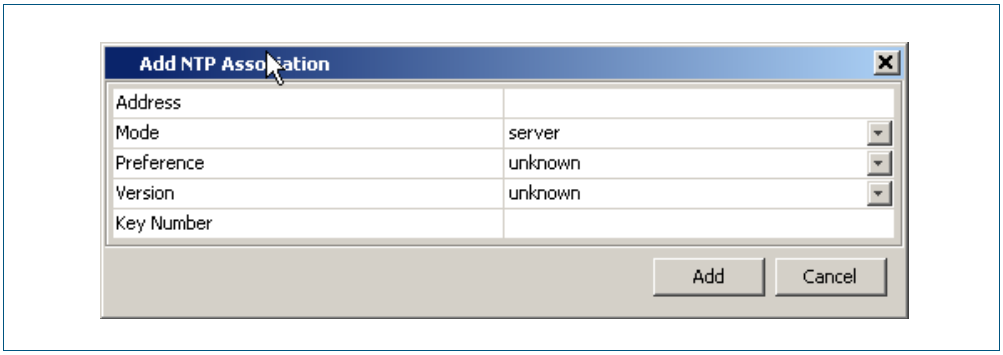
Label / Field / Button(cont.)	Description(cont.)
Associations / Stratum	The number of hops between the server and the accurate time source.
Associations / Poll	The time between NTP requests from the device to the server.
Associations / Reach	Shows whether or not the NTP server responded to the last request, which indicates the reachability of the NTP peer.
Associations / Delay	The round trip delay between the device and the server.
Associations / Offset	The difference between the device clock and the server clock, relative to the server clock, in milliseconds.
Associations / Dispersion	The lowest measure of error associated with peer offset based on delay.

Management > NTP > Add NTP Association

The Management > NTP > Add NTP Association dialog allows you configure Network Time Protocol (NTP) peer configurations on the switch.

Configuration Dialog

Figure C-49: Example showing the **Management > NTP > Add NTP Association** dialog:



Description

Label / Field / Button	Description
Address	Enter the NTP IPv4 address for the NTP peer or NTP server used.
Mode	Select one of the server or peer options from the drop down list to specify the NTP Mode used. When using NTP server mode, the NTP server will not accept updates from clients for updates to the server's time settings. The NTP server is configured to synchronize the NTP clients. When using NTP peer mode, each device shares its time information with the other, and each device can also provide time synchronization to the other.

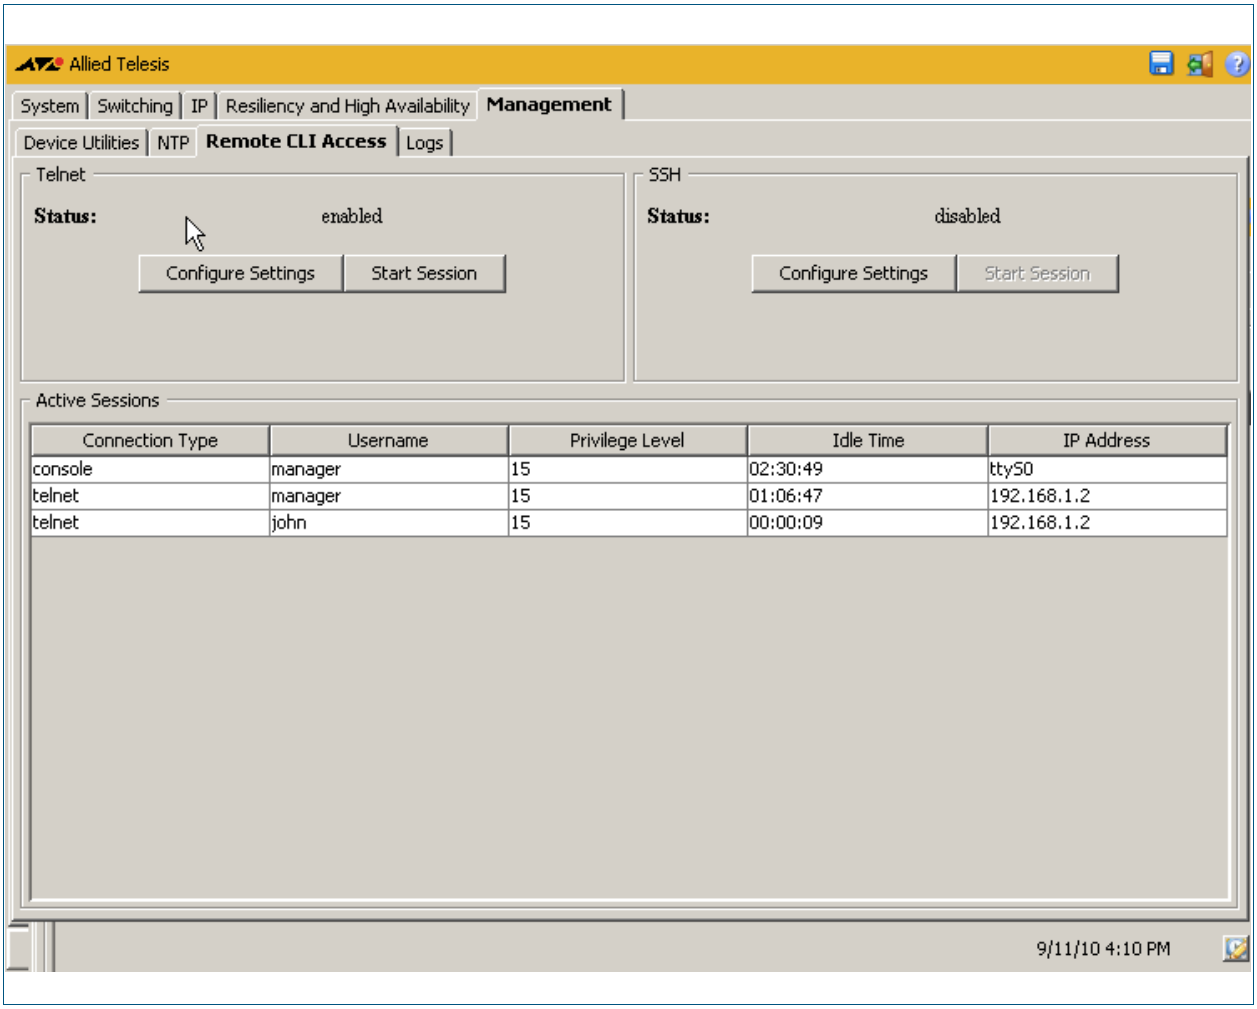
Label / Field / Button(cont.)	**Description**(cont.)
`Preference`	Select one of the `unknown`, `not preferred`, or `preferred` options from the drop down list to specify the NTP Preference used. NTP Preference is used to configure an NTP server, so the NTP server is given preference to synchronize the NTP clients.
`Version`	Select one of the `unknown`, `version 1`, `version 2`, `version 3`, or `version 3, version 4` options from the drop down list to specify the NTP Version used.
`Key Number`	Enter the NTP Key Number for NTP authentication, which allows NTP to authenticate the associations with other systems for security purposes. The NTP Key Number is an integer in the range <1-4294967295>. The MD5 (Message-Digest algorithm 5) key type is supported to encrypt the NTP Key Number used for authentication.

Management > Remote CLI Access

The Management > Remote CLI Access menu tab allows you to enable, disable and configure Telnet and SSH.

You can create Telnet or SSH connections to the switch, and you can view a list of all current active CLI sessions on the switch from this tab.

Menu Tab Figure C-50: Example showing the **Management > Remote CLI Access** menu tab:



Description

Label / Field / Button	Description
`Telnet / Status`	Displays the current Telnet status, either '`enabled`' or ''`disabled`'.
`Telnet / Configure Settings`	Configures the Telnet Status. Select '`enabled`' or '`disabled`' to configure the status of the Telnet server on the switch.
`Telnet / Start Session`	Starts a Telnet session to use the CLI. After starting a Telnet session you will need to login to the switch to use the CLI.
`SSH / Status`	Displays the current SSH status, either '`enabled`' or '`disabled`'.

Label / Field / Button(cont.)	**Description**(cont.)
SSH / Configure Settings	Configures the SSH Status. Select 'enabled' or 'disabled' to configure the status of the SSH server on the switch. Note that relevant certificates must be installed to initiate an SSH session.
SSH / Start Session	Starts a secure SSH session to use the CLI. After starting an SSH session you will need to login to the switch to use the CLI.

Description

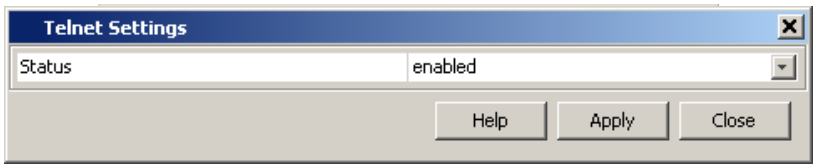
Label / Field / Button	Description
`Active Sessions / Connection Type`	A Console connection or a VTY connection.
`Active Sessions / Username`	Login name for a user.
`Active Sessions / Privilege Level`	The privilege set for a user for VTY or console connection. Privilege levels range from 0-15 with 15 the highest privilege level. Privilege levels are used in the CLI to enable or disable access to different configuration modes and commands. Privilege levels 0-14 only enables users to view system configuration and system behavior. Privilege level 15 enables users to globally configure all the interfaces on a switch.
`Active Sessions / Idle Time`	Time in seconds that the SSH Server waits to receive data from the SSH Client. The SSH Server disconnects when the Idle Time limit is reached.
`Active Sessions / IP Address`	The IPv4 address for the VTY connection.

Management > Remote CLI Access > Telnet Settings

The Management > Remote CLI Access > Telnet Settings dialog allows you to enable or disable Telnet.

Configuration Dialog

Figure C-51: Example showing **Management > Remote CLI Access > Telnet Settings** dialog:



Description

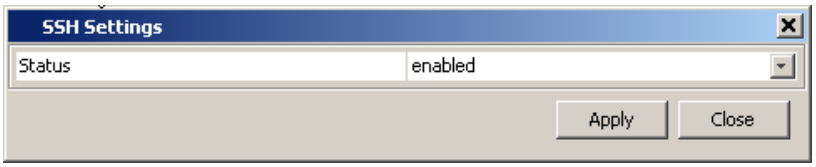
Label / Field / Button	Description
`Status`	Select `enabled` or `disabled` from the drop down list on this dialog to enable or disable Telnet respectively on the switch.

Management > Remote CLI Access > SSH Settings

The Management > Remote CLI Access > SSH Settings dialog allows you to enable or disable SSH.

Configuration Dialog

Figure C-52: Example showing the **Management > Remote CLI Access > SSH Settings** dialog:



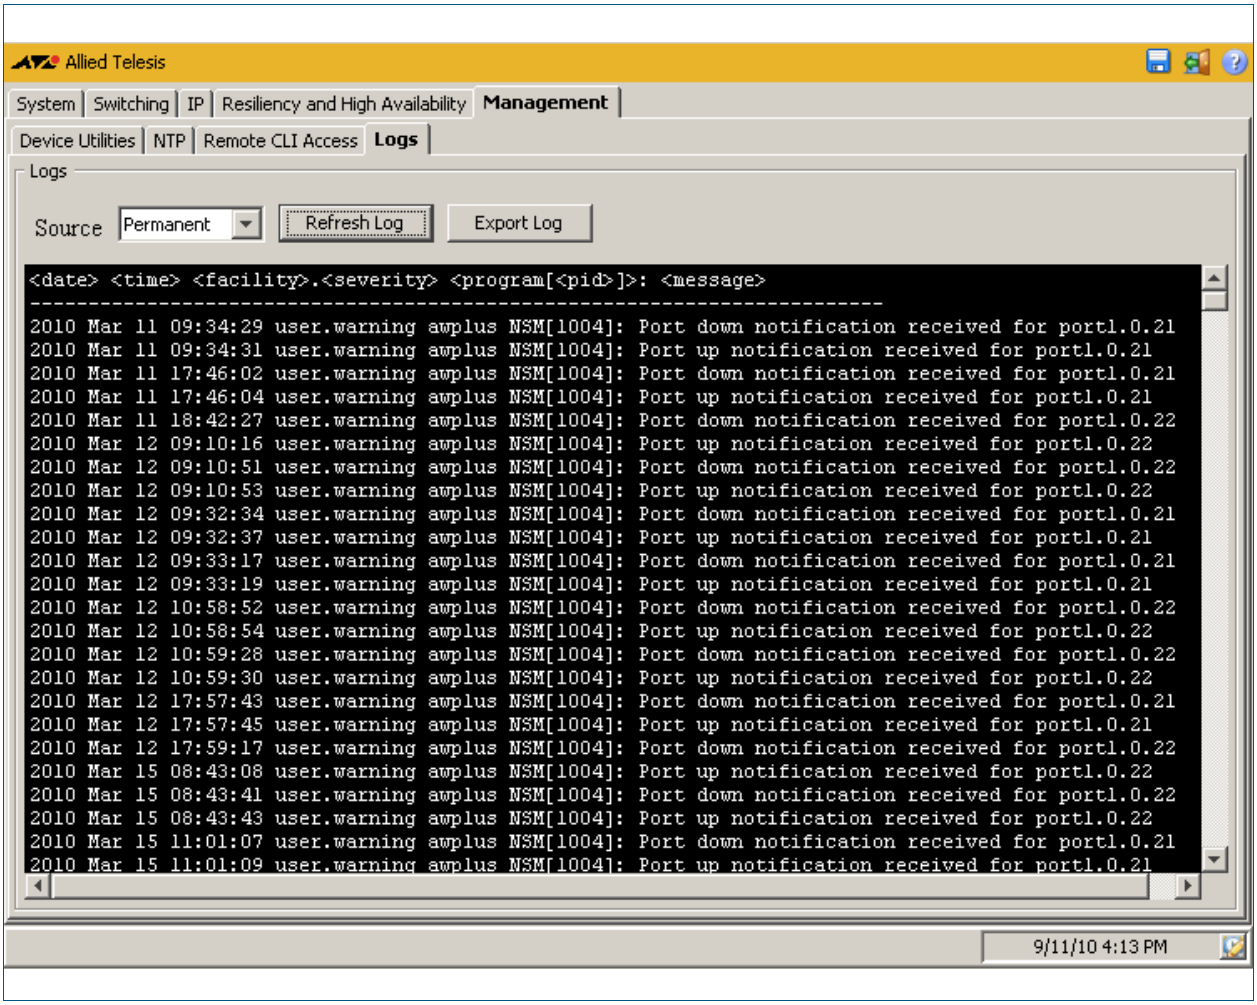
Description

Label / Field / Button	Description
`Status`	Select `enabled` or `disabled` from the drop down list on this dialog to enable or disable SSH respectively on the switch.

Management > Logs

The Management >Logs menu tab allows you to view the switch logs, and export the switch logs as .csv format files.

Menu Tab Figure C-53: Example showing the **Management > Logs** menu tab:



Description

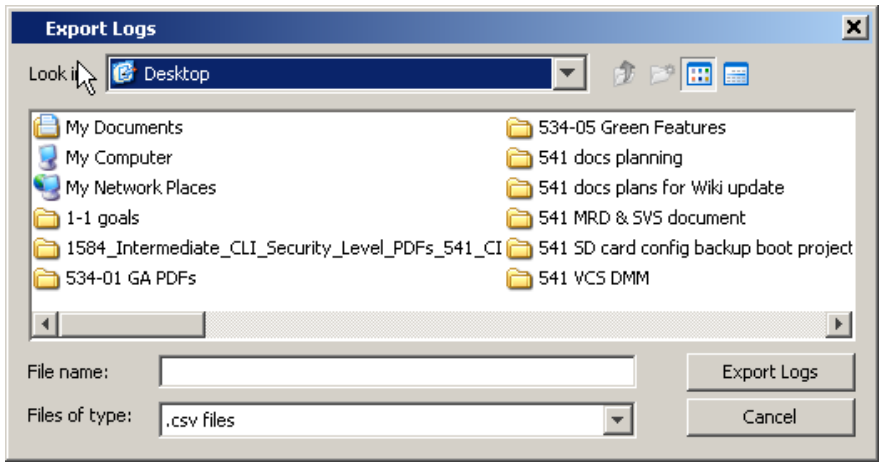
Label / Field / Button	Description
`Logs`	Display, select and export the available switch log files for troubleshooting use.
`Source`	Select the buffered log or the permanent log available on the switch to display or export to a .csv format file for use in a spreadsheet.
`Source / Refresh Log`	Select this button to display an updated buffered or permanent log.
`Source / Export Log`	Select this option to export the log to a .csv format file for use in a spreadsheet.

Management > Logs > Export Logs

The Management > Logs > Export Logs dialog allows you to export the switch logs as .csv format files.

Configuration Dialog

Figure C-54: Example showing the **Management > Logs > Export Logs** dialog:



Description

Label / Field / Button	Description
`File name:`	Enter the file name for the exported log file.
`Files of type:`	Select `.csv files` to export the log file as a comma separated file, so each column of the log file can be formatted in a spreadsheet.

Numerics

6to4 automatic tunneling

IPv6 transition is required to migrate from IPv4 to IPv6. One method to connect to the global IPv6 network over the existing IPv4 network is called 6to4 automatic tunneling. Although this method is called '6to4 tunneling', it does not involve discrete point-to-point tunnels. The 'tunneling' in '6to4 tunneling' refers to the fact that the IPv6 packets are encapsulated in IPv4 packets to be 'tunneled' across the IPv4 domain. Hence, '6to4 tunneling' is primarily a scheme for encapsulating IPv6 packets inside IPv4 headers.

For more information and a configuration example see "6to4 Automatic Tunnel Configuration" on page 28.2.

10BaseT

10 Mbps/baseband/twisted pair. The IEEE standard for twisted pair Ethernet.

802.1X

IEEE 802.1x is an IEEE Standard for port-based Network Access Control (NAC). It is part of the IEEE 802.1 group of networking protocols. It provides an authentication mechanism to devices wishing to attach to a LAN, either establishing a point-to-point connection or preventing it if authentication fails. It is used for securing wireless 802.11 access points and is based on the Extensible Authentication Protocol (EAP). Authentication is required on a per-port basis. The main components of an 802.1X implementation are:

- The authenticator - the port on this device that wishes to enforce authentication before allowing access to services that are accessible behind it.
- The supplicant - the port that wishes to access services offered by the authenticator's system. The supplicant may be a port on a PC or other device connected to this device.
- The authentication server - a device that uses the authentication credentials supplied by the supplicant, via the authenticator, to determine if the authenticator should grant access to its services.

See AAA and tri-authentication.

For a configuration example see "Configuring 802.1X" on page 62.2. For a sample configuration script see "Sample 802.1X Authentication Configuration" on page 66.7.

A

AAA

AAA is the collective title for the three related functions of Authentication, Authorization and Accounting. These function can be applied in a variety of methods with a variety of servers.

Authentication is performed in the following contexts:

- Login authentication of user shell sessions on the console port, and via telnet/SSH.
- 802.1X authentication of devices connecting to switch ports.
- MAC authentication of devices connecting to switch ports.
- Web-authentication of devices connecting to switch ports.

Accounting is performed in the following contexts:

- Accounting of console login sessions.
- Accounting of 802.1x authenticated connections.
- Accounting of MAC authenticated connections.
- Accounting of Web authenticated connections.

There are two types of servers that can be used:

- Local user database.
- RADIUS servers.

When 802.1X authentication, MAC authentication and Web-authentication are configured to run simultaneously on a switch port this is called tri-authentication.

For more information see Chapter 66, AAA Introduction and Configuration. For a configuration example see "Configuring AAA Login Authentication" on page 66.5. For sample 802.1x, MAC authentication and Web-authentication configuration scripts see "Sample Authentication Configurations" on page 66.7.

access-list

See ACL.

ACL

Access Control List. An ACL is one filter, or a sequence of filters, that are applied to an interface to either block, pass, or when using QoS, apply priority to, packets that match the filter definitions. ACLs are used to restrict network access by hosts and devices and to limit network traffic. See ACL sequence numbers and ACL types.

For more information see Chapter 55, Access Control Lists Introduction.

ACL sequence numbers

To help manage ACLs you can apply sequence numbers to filters. This allows you to remove filters from named and numbered ACLs without having to reconfigure an ACL. The ability to add sequence numbers to filters simplifies updates through the ability to position a filter within an ACL. When you add a new filter, you can specify a sequence number to position the filter in the ACL and you can also remove a current filter in an ACL by specifying a sequence number.

For more information see "ACL Filter Sequence Numbers" on page 55.15.

ACL types

ACLs are separated into two different types, software ACLs and hardware ACLs.

Hardware ACLs are applied directly to an interface, or are used for QoS classifications. They can be either named, or can use the following numeric ranges:

- 3000-3699 for Hardware IP ACLs
- 4000-4699 for Hardware MAC ACLs

For more information see "Defining Hardware IP ACLs" on page 55.6 and "Defining Hardware MAC ACLs" on page 55.5.

Software ACLs can be either named ACLs, using the standard or extended keyword followed by a text string, or they can use the following numeric ranges:

- 1-99
- 100-199
- 1300-1999
- 2000-2699

Software ACLs are used in features such as SNMP, IGMP, BGP and OSPF.

Active Master

The switch that manages the stack, or VCStack, also referred to as the Stack Master.

See Disabled Master for information about how this relates to Stack Master or Active Master.

Address resolution

The process of resolving and mapping hardware MAC addresses into their corresponding network layer IP addresses. Depending on the underlying network, address resolution may require broadcasts on a local network.

For more information see "ARP" on page D.4.

Adjacency

A state existing between two OSPF routers. These routers build their routing databases by exchanging link state advertisements, often termed hello messages. When a pair has completed the process, the routers are said to be "adjacent."

ARP

Address Resolution Protocol. ARP is used by your device to dynamically learn the Layer 2 address of devices in its networks. Most hosts also have a MAC physical address in addition to the assigned IP address. For Ethernet, this is a 6-byte, globally unique number. ARP enables your device to learn the physical address of the host that has a given IP address.

For more information see "Address Resolution Protocol (ARP)" on page 24.3.

AS

Autonomous System. A group of networks with a common routing infrastructure. An AS runs interior gateway protocols (IGPs) such as RIP and OSPF within its boundaries and uses exterior gateway protocols (EGPs) such as BGP to exchange routing information with other ASs.

ASCII

The *American Standard Code for Information Interchange*. A standard character-to-number encoding widely used within the computer industry.

ASIC

Application Specific Integrated Circuit. An integrated circuit (chip) manufactured to perform a specific function.

asynchronous

Transmission in which each character is sent individually. The time intervals between transmitted characters may be of unequal length. Transmission is controlled by start and stop elements before and after each character. See "synchronous" on page D.29

autonegotiation

Autonegotiation lets the port adjust its speed and duplex mode to accommodate the device connected to it. When the port connects to another autonegotiating device, they negotiate the highest possible speed and duplex mode for both of them.

autonomous system

See AS.

B

BGP

Border Gateway Protocol. BGP is an exterior gateway protocol that determines the best path in networks, performs optimal routing between multiple autonomous systems or domains, and exchanges routing information with other BGP systems. The RFCs 1771 (BGP4), 1654 (first BGP4 specification), and 1105, 1163, 1267 (older version of BGP) describe BGP and BGP4.

For more information see "BGP" on page 30.3. For configuration examples see "Enabling BGP Peers In The Same Autonomous System" on page 41.2, "Enabling BGP Between Different Autonomous Systems" on page 41.4, "Route Reflector" on page 41.5, "Confederations" on page 41.7, "BGP Authentication" on page 41.10, "Configuring BGP Graceful Reset" on page 41.12 and "Configuring BGP Graceful Restart" on page 41.14.

BGP filter types

There are four filter types that can be applied to the BGP updates being exchanged between BGP peers:

- Distribute filters - these use ACLs and look at the individual prefixes within an update message. If a prefix within the update message matches the filter criteria then that individual prefix is filtered out or accepted depending on what action the filter entry has been configured to carry out. Note that you cannot combine distribute filters and prefix filters.
- Path filters - these look at the AS-Path attribute in update messages. If the AS-Path attribute in the update matches the filter criteria then the whole update message is filtered out or accepted, depending on what action the filter entry has been configured to carry out.
- Prefix filters - these use prefix lists and look at the individual prefixes within an update message. If a prefix within the update message matches the filter criteria then that individual prefix is filtered out or accepted depending on what action the filter entry has been configured to carry out. Note that you cannot combine distribute filters and prefix filters.
- Route maps - these have a complex combination of match criteria and actions. They can be used to filter out routes and also to alter the attributes in update messages.

All these filter types can be used in incoming or outgoing directions. Therefore, all the filters can all be used to filter the update packets that are received from a peer, or the update packets which the router itself is sending to a peer.

BGP peers

Within the BGP protocol, the exchange of routing information is carried out between pairs of routers. Two routers create a TCP connection with each other, and exchange routing information as specific data packets within that TCP session. The routers at the ends of the TCP connection are referred to as BGP peers. Any given router can form peering relationships with multiple routers.

BGP updates

Once a router has established a BGP connection with a peer, it will start to exchange routing information with that peer. A BGP update message is the packet that is used to transfer the routing information.

BIST

Built In Self Test. A mechanism that permits the device to test itself.

Blackhole route

A blackhole route is a routing table entry that does not forward packets. A blackhole route is specified as an interface with an ip route command. Note that a blackhole route is also called a Null route.

B-MAC

Backbone MAC address.

BPDU

Bridge Protocol Data Unit. A spanning tree protocol initializing packet sent at configurable intervals to exchange information among bridges in the LAN.

For information on the standardized format for MSTP BPDU messages see "MSTP Bridge Protocol Data Units (BPDUs)" on page 18.17.

bridge

A device that connects two or more networks and forwards packets between them. Bridges function at the data link layer or Layer 2 of the OSI reference model. A bridge will filter, send or flood an incoming frame, base on the MAC address of that frame.

broadcast

One device sends out data that is intended to be received and processed by every device that it reaches.

broadcast domain

A section of an Ethernet network comprising all the devices that will receive broadcast packets sent by any device in the domain. Separated from the rest of the network by a Layer 3 switch.

BOOTP

Bootstrap Protocol. BOOTP is a UDP-based protocol that enables a booting host to dynamically configure itself without external interventions. A BOOTP server responds to requests from BOOTP clients for configuration information, such as the IP address the client should use.

B-TAG

Backbone TAG Field.

B-VID

Backbone VLAN ID (tunnel).

B-VLAN

Backbone VLAN (tunnel).

C

CHAP

Challenge Handshake Authentication Protocol. CHAP is an authentication method used by PPP servers to validate the identity of clients. CHAP verifies the identity of the client by using a three-way handshake, and the verification is based on a shared secret by the client and the server, such as the client's password.

CIST

Common and Internal Spanning Tree. The CIST is the default spanning tree instance of MSTP, i.e. all VLANs that are not members of particular MSTIs are members of the CIST. Also, an individual MST region can be regarded as a single virtual bridge by other MST regions. The spanning tree that runs between regions is the CIST. The CIST is also the spanning tree that runs between MST regions and Single Spanning Tree (SST) entities.

For more information see "Common and Internal Spanning Tree (CIST)" on page 18.15.

classification

In ACLs and QoS, classification is the process of filtering and marking. Filtering involves sorting your data into appropriate traffic types. Marking involves tagging the data so that downstream ports and routers can apply appropriate service policy rules. There are two reasons to classify data:

- To provide network security (security ACLs).
- To apply service quality criteria QoS.

The main application of security ACLs is to block undesired traffic. When using ACLs though QoS, the same classification and action abilities are available, but QoS has some additional fields that it can match on and also provides the ability to perform metering, marking and remarking on packets that match the filter definitions.

For more information on ACL classification see "Profile Limitations" on page 55.9. For more information on QoS classification see "Classifying your Data" on page 60.7.

class maps

Class maps are among the pivotal QoS components. They provide the means that associate the classified traffic with its appropriate QoS actions. They are the linking elements for the following functions:

- classification.
- policy mapping. See policy maps.
- aggregate policing and metering
- premarking.

The relationship between a class map and a policy map can be one-to-one or many-to-one.

For more information see "Class Maps" on page 60.7.

CLI

Command Line Interface. With three distinct modes, the CLI is very secure. In User exec mode you can view settings and troubleshoot problems but you cannot make changes to the system. In Privileged exec mode you can change system settings and restart the device. You can only make configuration changes in Global configuration mode, which reduces the risk of making accidental configuration changes.

For more information see "How to Work with Command Modes" on page 1.10 and "Commands Available in each Mode" on page 1.43.

C-MAC

Customer MAC Address.

collision domain

A physical region of a local area network (LAN) in which data collisions can occur.

continuous reboot prevention

The continuous reboot prevention feature allows the user to configure a switch to stop rebooting if the device gets into a cycle of continuous rebooting. The user can configure the time period, the maximum number of times the switch can reboot within the specified time period, referred to as the threshold, and the action to take if the threshold is exceeded.

For more information see "Continuous Reboot Prevention" on page 1.39.

Control Plane Prioritization

Control Plane Prioritization (CPP) allows you to allocate priorities to packet types to ensure minimum interruption to the flow of control information through the network. CPP stops the control plane from being flooded by traffic in the event of a network storm or Denial of Service (DoS) attack. This ensures maximal performance and prevents network outages. In addition, with CPP you can also limit the amount of traffic that flows to the CPU to ensure that performance of other services, such as the CLI, are not affected during network storms or DoS attacks.

For more information see the platform control-plane-prioritization rate command on page 15.24.

control VLAN

In EPSR, the VLAN over which all control messages are sent and received. EPSR never blocks this VLAN.

For more information see "Ring Components and Operation" on page 81.2.

CoS

Class of Service. CoS is a method for classifying traffic on a packet by packet basis using information in the type-of-service (ToS) byte to provide different service levels to different traffic. See QoS.

For more information see "CoS to egress queue premarking" on page 60.11.

cost

An indication of the overhead required to send packets across a certain interface.

CPP

Control Plane Prioritization. See Control Plane Prioritization.

C-TAG

Customer VLAN TAG.

C-VID

Customer VLAN ID.

C-VLAN

Customer VLAN.

D

data VLAN

In EPSR, a VLAN that needs to be protected from loops. Each EPSR domain has one or more data VLANs.

For more information see "Ring Components and Operation" on page 81.2.

designated bridge

Each bridge or LAN in the spanning tree, except the root bridge, has a unique parent, known as the designated bridge. Each LAN has a single bridge, called the designated bridge, that connects it to the next LAN on the path towards the root bridge.

For an overview of spanning tree operation see "Spanning tree operation" on page 18.2.

DHCP

Dynamic Host Configuration Protocol. A method of automatically allocating IP addresses. A DHCP server holds a pool of IP addresses from which it draws individual ones as it allocates them to users when they log on.

For more information see Chapter 85, Dynamic Host Configuration Protocol (DHCP) Introduction.

DHCP leasequery

The DHCP Leasequery protocol (RFC 4388) allows a device or process, for example a DHCP relay agent, to obtain IP address information directly from the DHCP server using DHCPLEASEQUERY messages.

For more information see "Enable DHCP Leasequery" on page 85.5.

DHCP lease probing

Probing is used by the DHCP server to check whether an IP address it wants to lease to a client is already being used by another host. Probing is configured on a per-DHCP pool basis.

For more information see "DHCP Lease Probing" on page 85.7.

DHCP Option 82

Enabling the DCHP Option 82 feature on the switch allows the switch to insert extra information into the DHCP packets that it is relaying. The information is stored in a specific optional field in the DHCP packet, namely, the agent-information field, which has option ID 82.

Note that the Option 82 agent information inserted by the DHCP snooping differs from the information added by DHCP Relay. The switch cannot be configured to use both the DHCP relay agent option and DHCP snooping.

For information about the Option 82 agent information added by DHCP Relay see "DHCP Relay Agent Option 82" on page 85.9.

For information about the Option 82 agent information inserted by DHCP snooping see "DHCP Option 82" on page 77.4.

DHCP relay agents

DHCP relay agents pass BOOTP and DHCP messages between servers and clients. Networks where the DHCP or BOOTP server does not reside on the same IP subnet as its clients need the intermediate routers to act as relay agents.

For information on how to configure the DHCP relay agent see "DHCP Relay Agent Introduction" on page 85.8.

DHCP snooping

DHCP snooping provides an extra layer of security on the switch via dynamic IP source filtering. DHCP snooping filters out traffic received from unknown, or 'untrusted' ports, and builds and maintains a DHCP snooping database.

With DHCP snooping, IP sources are dynamically verified, and filtered accordingly. IP packets that are not sourced from recognized IP addresses can be filtered out. This ensures the required traceability.

For more information see Chapter 77, DHCP Snooping Introduction and Configuration. For a configuration example see "Configure DHCP Snooping" on page 77.10.

Digital Diagnostics Monitoring (DDM)

Modern optical SFP transceivers support Digital Diagnostics Monitoring (DDM) functions. This feature allows you to monitor real-time parameters of the SFP, such as optical output power, optical input power, temperature, laser bias current, and transceiver supply voltage. Additionally, RX LOS (Loss of Signal) is shown when the received optical level is below a preset threshold. Monitoring these parameters allows you to check on the health of all installed SFPs or a specific SFP transceiver. See also Trouble-shoot fiber and pluggable issues in Getting Started.

SFP transceivers that support DDM display the following output from the show system pluggable detail and the show system pluggable diagnostics commands for monitoring SFPs:

- Diagnostic Calibration: Specifies whether the pluggable supports DDM Internal Calibration. Internal is displayed if the pluggable supports DDM Internal Calibration.
- Power Monitoring: Displays the received power measurement type, which can be either OMA (Optical Module Amplitude) or Avg (Average Power) measured in µW.

For further information about the DDM feature on the switch for installed SFP transceivers, see the show system pluggable detail command and the show system pluggable diagnostics command in Chapter 8, System Configuration and Monitoring Commands. See also Digital Optical Monitoring (DOM). Note DOM is for XFP pluggable transceivers only.

Digital Optical Monitoring (DOM)

Modern optical XFP transceivers support Digital Optical Monitoring (DOM) functions. This feature allows you to monitor real-time parameters of the XFP, such as optical output power, optical input power, temperature, laser bias current, and transceiver supply voltage. Additionally, RX LOS (Loss of Signal) is shown when the received optical level is below a preset threshold. Monitoring these parameters allows you to check on the health of all installed XFPs or a specific XFP transceiver. See also Trouble-shoot fiber and pluggable issues in Getting Started.

XFP transceivers that support DOM display the following output from the show system pluggable detail and the show system pluggable diagnostics commands for monitoring XFPs:

- Diagnostic Calibration: Specifies whether the pluggable supports DOM Internal Calibration. Internal is displayed if the pluggable supports DOM Internal Calibration.
- FEC BER support: Specifies whether the FEC (Forward Error Correction) coder can generate a BER (Bit Error Rate) signal to tune the XFP transceiver if DOM is supported.

For further information about the DOM feature on the switch for installed XFP transceivers, see the show system pluggable detail command and the show system pluggable diagnostics command in Chapter 8, System Configuration and Monitoring Commands. See also Digital Diagnostics Monitoring (DDM). Note DDM is for SFP and SFP+ pluggable transceivers.

Disabled Master

The Disabled Master is a variant of the Stack Master or Active Master and is used with the DMM (Disabled Master Monitoring)feature. The Disabled Master has the same configuration as the Stack Master or Active Master, but has all its switchports disabled. The Disabled Master is only used is the stack separates into two stubs. By having all switchports disabled, the Disabled Master avoids potentially detrimental network connectivity problems from having two Stack Masters or Active Masters having the same configuration. The Stack Master's or Active Master's ports are unaffected by the Disabled Master's ports, so the Stack Master or Active Master continues to forward traffic normally.

For information about the Disabled Master and the Disabled Master Monitoring feature, see the Disabled Master Monitoring (DMM) section in Chapter 102, Stacking Introduction and the stack disabled-master-monitoring command in Chapter 103, Stacking Commands.

DLF

Destination Lookup Failure. DLF is the event of receiving a unicast Ethernet frame with an unknown destination address.

DMM (Disabled Master Monitoring)

The Disabled Master Monitoring (DMM) features checks the status of the Active Master via the Stack Resiliency Link. If the Active Master fails then the Disabled Master changes state to Active Master. A Disabled Master has the same configuration as the Active Master, but has all links shutdown. This change in state for the Disabled Master to become the Active Master allows traffic forwarding to continue on the VCStack.

For information about the Disabled Master and the Disabled Master Monitoring feature, see the Disabled Master Monitoring (DMM) section in Chapter 102, Stacking Introduction and the stack disabled-master-monitoring

DNS

Domain Name System. DNS allows you to access remote systems by entering human-readable device host names rather than IP addresses. DNS works by creating a mapping between a device name, such as www.alliedtelesis.com, and its IP address. These mappings are held on DNS servers. The benefits of DNS are that domain names:

- Can map to a new IP address if the host's IP address changes.
- Are easier to remember than an IP address.
- Allow organizations to use a domain name hierarchy that is independent of any IP address assignment.

For more information see "Domain Name System (DNS)" on page 24.8.

DNS Relay

DNS Relay provides the presence of a local virtual DNS server on your AlliedWare Plus™ device which can service DNS lookup requests sent to it from local hosts. The DNS Relay will usually relay the requests to an external, or upstream, DNS server.

For more information see "DNS Relay" on page 24.10.

DoS

Denial of Service. A generic term for attacks that reduce or stop the operation of a network.

DSCP value

The Differentiated Services Code Point within the TOS field of an IP packet header. This is a 6-bit number in the range 0-63.

duplex mode

See full duplex and half duplex.

dynamic channel group

A dynamic channel group also known as a LACP channel group, an etherchannel, or a LACP aggregator, enables a number of ports to be dynamically combined to form a single higher bandwidth logical connection. See LACP.

For an more information see "Link Aggregation Control Protocol (LACP)" on page 20.2. For a configuration example see "Configuring an LACP Channel Group" on page 20.5.

Dynamic Link Failover

Dynamic Link Failover (Host Attach) is a versatile feature that enables devices that do not support link aggregation to form multiple active links by using triggers and scripts. You can customize Dynamic Link Failover to suit almost any situation, from a simple redundant backup link to multiple active links capable of basic load-sharing.

E

EAP

Extensible Authentication Protocol. EAP carries out the authentication exchange between the supplicant and the authentication server.

etherchannel

See dynamic channel group.

Ethernet Protection Switching Ring

See EPSR.

EPSR

EPSR (Ethernet Protection Switching Ring) operates on physical rings of switches (note, not on meshed networks). When all nodes and links in the ring are up, EPSR prevents a loop by blocking data transmission across one port. When a node or link fails, EPSR detects the failure rapidly and responds by unblocking the blocked port so that data can flow around the ring. The EPSR components are:

- EPSR domain
- master node
- transit node
- ring port
- primary port
- secondary port
- control VLAN
- data VLAN

For more information and example configurations see Chapter 81, EPSR Introduction and Configuration.

EPSR domain

A protection scheme for an Ethernet ring that consists of one or more data VLANs and a control VLAN.

For more information see “Ring Components and Operation” on page 81.2.

EGP

Exterior Gateway Protocol. EGP is an obsolete protocol that has been replaced by BGP. Not to be confused with the general term exterior gateway protocol.

egress

Outgoing packet process.

exterior gateway protocol

A protocol that distributes routing information to devices that connect separate autonomous systems (ASs).

F

FDB

Forwarding Database.

FIB

Forwarding Information Base. The RIB (Routing Information Base) populates the FIB with the best route to each destination. When your device receives an IP packet, and no filters are active that would exclude the packet, it uses the FIB to find the most specific route to the destination. If your device does not find a direct route to the destination, and no default route exists, it discards the packet and sends an ICMP message to that effect back to the source.

For more information see "RIB and FIB Routing Tables" on page 31.4.

full duplex

When a port is in full duplex mode, the port transmits and receives data simultaneously. See half duplex.

G

Guest VLAN

If 802.1X authentication has been configured on access ports in the network, you might still want to provide limited network access to those users whose devices do not have 802.1x supplicant enabled, or who have unrecognized authentication credentials. The mechanism to achieve this is known as a Guest VLAN. The idea is that if the users device fails 802.1X authentication, or is not even performing any 802.1X authentication, then its connection port can be put into the guest VLAN.

For more information see "Guest VLAN Enhancements" on page 64.10 and the auth guest-vlan command on page 65.9. For a configuration example see "Configuring a Guest VLAN" on page 64.3.

H

half duplex

When a port is in half duplex mode, the port transmits or receives but not both at the same time. See full duplex.

hardware ACLs

See ACL types.

I

ICMP

Internet Control Message Protocol. ICMP allows networking devices to send information and control messages to other devices or hosts.

For more information see “Internet Control Message Protocol (ICMP)” on page 24.12.

ICMPv6

Internet Control Message Protocol Version 6. ICMPv6 is an implementation of ICMP for IPv6.

For more information see “The Internet Control Message Protocol (ICMPv6)” on page 26.7.

IGMP

Internet Group Management Protocol. IGMP is a communications protocol that hosts use to indicate that they are interested in receiving a particular multicast stream.

IGMP querier or router

A device in a subnetwork that is the coordinator for all multicast streams and IGMP membership information. Each subnet only has one active querier.

IGMP snooper

A device that spies on IGMP messages to create flow efficiencies by ensuring that multicast data streams are only sent to interested ports. A snooper can decide on the best path to send multicast packets at Layer 2 but does not initiate any IGMP communications.

For a configuration example see “IGMP Snooping and Querier configuration example” on page 48.5.

IGP

Interior Gateway Protocol. A routing protocol used within an autonomous system (AS).

ingress

Incoming packet process.

interior gateway protocol

See IGP.

IP directed broadcast

An IP directed broadcast is an IP packet whose destination address is a broadcast address for some IP subnet, but originates from a node that is not itself part of that destination subnet. When a directed broadcast packet reaches a switch that is directly connected to its destination subnet, the packet is flooded as a broadcast on the destination subnet. IP directed broadcast is enabled and disabled per VLAN interface. When enabled a directed broadcast packet is forwarded to an enabled VLAN interface if received on another subnet.

IP helper

The IP Helper feature allows the switch to receive UDP broadcasts on one subnet, and forward them as broadcasts or unicasts into another subnet, so a client can use an application which uses UDP broadcast (such as Net-BIOS) when the client and server are located in different subnets. The IP Helper feature forwards UDP broadcast network traffic to specific hosts on another subnet and/or to the broadcast address of another subnet. When the IP Helper feature is enabled on a VLAN interface, the UDP broadcast packets received on the interface are processed for forwarding out through another interface into another subnet.

IRDP

ICMP Router Discovery Protocol. If this feature in configured, the device sends router advertisements periodically and in response to router solicitations. ICMP Router Discovery messages let routers automatically advertise themselves to hosts.

For more information see "ICMP Router Discovery Protocol (IRDP)" on page 24.13.

I-SID

Extended Service ID.

ISP

Internet Service Provider. An organization that offers its customers access to the Internet. The ISP connects its customers using a data transmission technology, such as dial-up or DSL etc.

I-TAG

Extended Service TAG.

L

LACP

Link Aggregation Control Protocol. LACP allows bundling of several physical ports to form a single logical channel providing enhanced performance and redundancy. The aggregated channel is viewed as a single link to each switch. The spanning tree views the channel as one interface and not as multiple interfaces. When there is a failure in one physical port, the other ports stay up and there is no disruption. LACP does not interoperate with devices that use Port Aggregation Protocol (PAgP).

For an more information see "Link Aggregation Control Protocol (LACP)" on page 20.2.

LACP aggregator

See dynamic channel group.

LACP channel group

See dynamic channel group.

LAG

See Link Aggregation Group.

Layer 3 switch

A Layer 3 switch is an optimized combination of routing software and specialized hardware. The software uses traditional methods (static routing commands, and routing protocols) to build up a table of the best routes to network destinations, and then writes them into a set of registers in the specialized forwarding hardware. The hardware then forwards packets, based on their Layer 3 address content, at very high data rates, using the values that are written into the registers.

Link Aggregation Group

A Link Aggregation Group is a collection of bundled switch ports for an aggregated link. Link aggregation is the bonding together of two or more data channels into a single channel that appears as single logical link of higher bandwidth increasing link performance and reliability.

For an more information see "Link Aggregation Control Protocol (LACP)" on page 20.2.
For a configuration example see "Configuring an LACP Channel Group" on page 20.5

Link Local Addresses

A Link Local Address is an IP (Internet Protocol) address that is only used for communications in the local network, or for a point-to-point connection. Routing does not forward packets with link-local addresses. IPv6 requires a link-local address is assigned to each interface, which has the IPv6 protocol enabled, and when addresses are assigned to interfaces for routing IPv6 packets.

Note that link-local addresses are retained in the system until they are negated by using the no variant of the command that established them. See the ipv6 enable command for more information.

Also note that the link-local address is retained in the system if the global address is removed using another command, which was not used to establish the link-local address. For example, if a link local address is established with the ipv6 enable command then it will not be removed using a no ipv6 address command.

LLDP

Link Layer Discovery Protocol. LLDP is a Layer 2 protocol that enables Ethernet network devices, such as switches and routers, to transmit and/or receive device-related information to or from directly connected devices on the network, and to store such information learned about other devices. LLDP is a link level ("one hop") protocol; LLDP information can only be sent to and received from devices that are directly connected to each other, or connected via a hub or repeater. Advertised information is not forwarded on to other devices on the network.

For more information see Chapter 90, LLDP Introduction and Configuration.
For configuration examples see "Configuring LLDP" on page 90.11.

LLDPDU

LLDP Data Unit. See LLDP advertisements.

LLDP advertisements

LLDP transmits advertisements as packets called LLDP Data Units (LLDPDUs). An LLDPDU consists of a set of Type-Length-Value elements (TLV), each of which contains a particular type of information about the device or port transmitting it.

LLDP-MED

Link Layer Discovery Protocol Media Endpoint Discovery. LLDP-MED is an enhancement to IEEE's 802.1AB LLDP, adding media and IP telephony-specific messages that can be exchanged between the network and endpoint devices.

For more information see "LLDP-MED" on page 90.3, "LLDP-MED: Location Identification TLV" on page 90.7 and "LLDP-MED Operation" on page 90.9. For the procedure to configure LLDP-MED see "Configure LLDP-MED" on page 90.14.

Local RADIUS Server

Local RADIUS Server provides a user authentication service feature.

For more information and configuration examples see Chapter 72, Local RADIUS Server Introduction and Configuration.

LSA

Link State Advertisement. OSPF sends link-state advertisements (LSAs) to all other routers within the same hierarchical area. Data on attached interfaces, metrics used, and other variables, are included in OSPF LSAs. As OSPF routers accumulate link-state data, they use the Shortest Path First (SPF) algorithm to calculate the shortest path to each node.

M

MAC address learning

A key optimization in Ethernet switching is that the flooding of unicast traffic is minimized. This is based on switches knowing which port to forward traffic to for given destination MAC addresses. Switches achieve this by the simple process of noting on which ports packets arrive from given MAC addresses, as those will be the ports to which return packets to those MAC addresses will need to be forwarded. This process is referred to as MAC address learning.

MAC authentication

The way that MAC-based authentication works is that when the supplicant device starts sending packets, the authenticating switch will extract the source MAC address from the packets, and send a RADIUS request that uses this MAC address as the username and password in the request. See AAA and tri-authentication.

For a sample configuration script see "Sample MAC Authentication Configuration" on page 66.8.

master node

In EPSR, the controlling node for a domain, responsible for polling the ring state, collecting error messages, and controlling the flow of traffic in the domain.

Master node states are:

- Complete - the state when there are no link or node failures on the ring.
- Failed - the state when there is a link or node failure on the ring. This state indicates that the master node received a Link-Down message or that the failover timer expired before the master node's secondary port received a Health message.

For more information see "Ring Components and Operation" on page 81.2.

MD5

Message Digest 5 authentication algorithm.

metering

See policing.

metric

The sum of all the costs along the path to a given destination. See cost.

MLD

Multicast Listener Discovery. MLD is used to exchange membership status information between IPv6 routers that support multicasting and members of multicast groups on a network segment. Host membership in a multicast group is reported by individual member hosts, and membership status is periodically polled by multicast routers.

MLD snooping

MLD snooping is a feature whereby a Layer 2 switch listens to or "snoops" the MLD messages passing through the switch or from member hosts and multicast routers. The purpose of MLD snooping is to provide efficient Layer 2 multicast forwarding, by sending only to hosts that have expressed an interest in receiving the multicast data.

For more information see Chapter 54, MLD Snooping Introduction and Commands.

MSTI

Multiple Spanning Tree Instance. MSTP enables the grouping and mapping of VLANs to different spanning tree instances. An MST Instance (MSTI) is a particular set of VLANs that are all using the same spanning tree.

For more information see "Multiple Spanning Tree Instances (MSTI)" on page 18.12.

MSTP

Multiple Spanning Tree Protocol. MSTP is similar to Rapid Spanning Tree Protocol (RSTP) - it provides loop resolution and rapid convergence. However it also has the extra advantage of making it possible to have different forwarding paths for different multiple spanning tree instances. This enables load balancing of network traffic across redundant links. A device running MSTP is compatible with other devices running RSTP or STP.

For more information see "Multiple Spanning Tree Protocol (MSTP)" on page 18.11. For a configuration example see "Configuring MSTP" on page 18.19.

MSTP Regions

An MST region is a set of interconnected switches that all have the same values for the following MST configuration identification elements:

- MST configuration name - the name of the MST region.
- Revision level - the revision number of configuration.
- Configuration Digest - the mapping of which VLANs are mapped to which MST instances.

Each of the MST instances created are identified by an MSTI number. This number is locally significant within the MST region. Therefore, an MSTI will not span across MST regions.

For more information see "MSTP Regions" on page 18.13.

multicast

One device sends out data that is intended to be received and processed by a selected group of the devices it reaches.

N

NAC

Network Access Control. NAC provides unprecedented control over user access to the network in order to mitigate threats to network infrastructure. NAC uses 802.1X port-based authentication with standards-compliant dynamic VLAN assignment, to assess a user's adherence to the network's security policies, and either grant authentication or offer remediation. NAC also supports alternatives to 802.1x port-based authentication, such as Web-authentication to enable guest access, and MAC authentication for end points that do not have an 802.1x supplicant. Furthermore, if multiple users share a port then multi-authentication can be used and a Guest VLAN can be configured to provide a catch-all for users without an 802.1x supplicant.

For more information see Chapter 62, 802.1X Introduction and Configuration and Chapter 64, Authentication Introduction and Configuration.

NAS

Network Access Server. A NAS is a single point of access to a remote resource. The client connects to the NAS. The NAS then connects to another resource asking whether the client's supplied credentials are valid. Based on that answer the NAS then allows or disallows access to the resource. The NAS contains no information about what resources clients can connect to or what client credentials are valid. The NAS sends the credentials the client supplied to a resource which then validates the client.

next hop

IP routing involves forwarding packets from one router to the next, until they reach their destination. Routers do not need to know the full path to a packet's destination, they just need to know the next router to forward the packet on to. This 'next router' is referred to as the next hop of an IP route.

Nested VLAN

See VLAN double tagging.

NTP

Network Time Protocol. NTP is a protocol for synchronizing the time clocks on a collection of network devices using a distributed client/server mechanism.

For more information see Chapter 83, NTP Introduction and Configuration.

Null route

A null route is a routing table entry that does not forward packets. A null route is specified as an interface with an ip route command. Note that a null route is also called a Blackhole route.

O

OSPF

Open Shortest Path First. A link-state routing protocol, OSPF is an interior gateway protocol (IGP) that uses the Shortest Path First (SPF) Dijsktra algorithm.

For more information see Chapter 37, OSPF Introduction and Configuration. For configuration examples see "Enabling OSPF on an Interface" on page 37.10, "Setting priority" on page 37.12, "Configuring an Area Border Router" on page 37.14, "Redistributing Routes Into OSPF" on page 37.15, "OSPF Cost" on page 37.16, "Configuring Virtual Links" on page 37.19 and "OSPF Authentication" on page 37.21.

P

PAP

Password Authentication Protocol. PAP is an authentication protocol that uses a password and is used by PPP to validate users before allowing them to access server resources. PAP transmits plain text ASCII passwords over the network so it is not secure.

PIM-DM

Protocol Independent Multicast - Dense Mode. PIM-DM is a data-driven multicast routing protocol, which builds source-based multicast distribution trees that operate on the Flood-and-Prune principle. It requires unicast-reachability information, but does not depend on a specific unicast routing protocol. PIM-DM is a significantly less complex protocol than PIM-SM. PIM-DM works on the principle that it is probable that any given multicast stream will have at least one downstream listener. PIM-DM is ideal where many hosts subscribe to receive multicast packets, so most of the PIM Routers receive and forward all multicast packets.

For more information see Chapter 52, PIM-DM Introduction and Configuration. For a configuration example see "PIM-DM Configuration" on page 52.4.

PIM-SM

Protocol Independent Multicast - Sparse Mode. PIM-SM provides efficient communication between members of sparsely distributed groups - the type of groups that are most common in wide-area internetworks. PIM-SM is designed on the principle that several hosts wishing to participate in a multicast conference does not justify flooding the entire internetwork with periodic multicast traffic. PIM-SM is designed to limit multicast traffic so that only those routers interested in receiving traffic for a particular group receive the traffic.

For more information see Chapter 50, PIM-SM Introduction and Configuration. For configuration examples see "Static Rendezvous Point configuration" on page 50.7, "Dynamic Rendezvous Point configuration" on page 50.9 and "Bootstrap Router configuration" on page 50.11.

ping

Ping tests the connectivity between two network devices to determine whether each network device can "see" the other device.

ping-of-death attack

A type of attack on a computer that involves sending a malformed or otherwise malicious ping to a network device.

ping polling

Ping polling is used to ensure that a device is still present, live, and contactable in the network by periodically sending a packet to an IP address and waiting for a response. Configurable actions can be performed if responses are no longer arriving.

For more information see Chapter 98, Ping Polling Introduction and Configuration. For how to configure ping polling see "Configuring Ping Polling" on page 98.4.

policing

In QoS, once you have set-up your classification and created your class maps, you can start conditioning your traffic flows. One tool used for traffic conditioning is the policer (or meter). The principle of policing is to measure the data flow that matches the definitions for a particular class-map; then, by selecting appropriate data rates, allocate the flows into one of three categories, Red Yellow or Green. You then decide what action to apply to the Red, Yellow and Green data. See premarking.

For more information see "Policing (Metering) Your Data" on page 60.15.

policy maps

Policy maps are the means by which you apply your class maps to physical switch ports. A policy map can be assigned to several ports, but a port cannot have more than one policy map assigned to it. See QoS.

For more information see "Policy Maps" on page 60.10.

port bit map

An efficient method for the storage of a list of ports. Each port is represented by a single bit in a 32-bit or 64-bit value.

port mirroring

Port mirroring enables traffic being received and transmitted on a switch port to be sent to another switch port, the mirror port, usually for the purposes of capturing the data with a protocol analyzer. The mirror port is the only switch port that does not belong to a VLAN, and therefore does not participate in any other switching. Before the mirror port can be set, it must be removed from all trunk groups and all VLANs except the default VLAN.

PPP

Point-to-Point Protocol. A data link protocol used to establish a direct connection between two networking nodes. PPP can provide connection authentication and transmission encryption. PPPoE (Point-to-Point Protocol over Ethernet) is used over broadband connections as is PPPoA (Point-to-Point Protocol over ATM) with DSL.

premarking

In QoS, premarking relates to adding QoS markers to your incoming data traffic before it is metered. QoS markers can be applied at both the link layer (within the CoS field), and at the network layer (within the DSCP field). See policing.

For more information see "Premarking Your Traffic" on page 60.11.

primary port

In EPSR, a ring port on the master node. This port determines the direction of the traffic flow, and is always operational.

For more information see "Ring Components and Operation" on page 81.2.

provisioning

Stack member provisioning is the pre-configuration of stack member position ready for insertion at a later time. Provisioning enables a network administrator to pre-configure vacant stack member capacity within a VCStack, ready to be hot-swapped in at a later time. Later, when the stack member switch is physically added, its configuration is automatically applied with the minimum network disruption.

For more information see "Provisioning (Stack Members)" on page 102.20.

proxy ARP

Proxy ARP allows hosts that do not support routing (i.e. they have no knowledge of the network structure) to determine the physical addresses of hosts on other networks.

For more information see "Proxy ARP" on page 24.4.

PSU

Power Supply Unit.

Q

Query Solicitation

Query Solicitation minimizes the loss of multicast data after a topology change on networks that use EPSR or spanning tree (STP, RSTP, or MSTP) for loop protection. Without Query Solicitation, when the underlying link layer topology changes, multicast data flow can stop for up to several minutes, depending on which port goes down and how much of the IGMP query interval remained at the time of the topology change. Query Solicitation greatly reduces this disruption.

For more information see "Query Solicitation" on page 48.7.

QoS

Quality of Service. QoS enables you to both prioritize traffic and limit its available bandwidth. The concept of QoS is a departure from the original networking protocols, in which all traffic on the Internet or within a LAN had the same available bandwidth. Without QoS, all traffic types are equally likely to be dropped if a link becomes oversubscribed. This approach is now inadequate in many networks, because traffic levels have increased and networks often carry time-critical applications such as streams of real-time video data. QoS also enables service providers to easily supply different customers with different amounts of bandwidth. Configuring Quality of Service involves two separate stages:

- Classifying traffic into flows, according to a wide range of criteria. Classification is performed by the switch's class maps.
- Acting on these traffic flows.

For more information see Chapter 60, Quality of Service (QoS) Introduction.

Quality of Service

See QoS.

R

RADIUS

Remote Authentication Dial-In User Service. RADIUS is a networking protocol that provides centralized AAA (Authentication Authorization and Accounting) management for clients to a network. RADIUS is a client/server protocol that runs in the application layer, using UDP (User Datagram Protocol) for data transport. RADIUS authenticates users before granting them access to network resources and can account for the usage of network resources.

For more information see Chapter 68, RADIUS Introduction and Configuration. For configuration examples see "RADIUS Configuration Examples" on page 68.14.

redistribute

Advertise routes learnt from one routing protocol into another routing protocol.

Remote Network MONitoring

See RMON.

resiliency link

In VCStack, an extra, out-of-band, data link between stack members. In the event of loss of communication across the stacking connection, the stack members can determine the status of other members via communication on the resiliency link. This assists the stack members in deciding the correct course of action when communication on the stack is lost.

For more information see "Stack Resiliency Link" on page 102.14.

RIB

Routing Information Base. The RIB records all the routes that your device has learnt. Your device uses the RIB to advertise routes to its neighbor devices and to populate the FIB (Forwarding Information Base).

For more information see "RIB and FIB Routing Tables" on page 31.4.

ring port

In EPSR, a port that connects the node to the ring. On the master node, each ring port is either the primary port or the secondary port. On transit nodes, ring ports do not have roles.

For more information see "Ring Components and Operation" on page 81.2.

RIP

Routing Information Protocol. A simple distance vector IPv4 routing protocol, RIP is an Interior Gateway Protocol (IGP) that uses hop counts as its metrics. Given a choice of routes, RIP uses the route that takes the lowest number of hops. If multiple routes have the same hop count, RIP chooses the first route it finds.The AlliedWare Plus™ RIP module supports RFCs 1058 and 1723; the RIPv2 module supports more fields in the RIP packets, and supports security authentication features.

For more information see "RIP" on page 30.2. For configuration examples see "Enabling RIP" on page 33.2, "Specifying the RIP Version" on page 33.4, "RIPv2 Authentication (Single Key)" on page 33.6, "RIPv2 Text Authentication (Multiple Keys)" on page 33.8 and "RIPv2 md5 authentication (Multiple Keys)" on page 33.12.

RIPng

Routing Information Protocol next generation. RIPng is a simple distance vector IPv6 routing protocol. It determines the number of hops between the destination and your device, where one hop is one link. Given a choice of routes, RIPng uses the route that takes the lowest number of hops. If multiple routes have the same hop count, RIPng chooses the first route it finds. RIPng is an extension of RIPv2 to support IPv6.

For configuration examples see "Enabling RIPng" on page 35.2 and "Troubleshooting RIPng Adjacency" on page 35.5.

RIPv6

See RIPng.

RMON

Remote Network MONitoring. RMON was developed by the IETF to support monitoring and protocol analysis of LANs with a focus on Layer 1 and 2 information in networks. RMON is an industry standard that provides the functionality in network analyzers. An RMON implementation operates in a client/server model. Monitoring devices (or 'probes') contain RMON agents that collect information and analyze packets. The probes are servers and the Network Management applications that communicate with them are clients.

For more information see Chapter 93, RMON Introduction and Configuration. For a configuration example see "RMON Configuration Example" on page 93.3.

Roaming Authentication

Roaming Authentication improves the usability of network security by enabling users to move within the network without requiring them to re-authenticate each time they move. If a supplicant (client device) moves from one wireless access point to another wireless access point, and the wireless access points are connected to different ports, then the switch (authenticator) recognizes that the supplicant has been authenticated and accepts the supplicant without requiring re-authentication.

For more information see "Roaming Authentication" on page 64.4.

root bridge

A single bridge is selected to become the spanning tree's unique root bridge. This is the device that advertises the lowest Bridge ID. Each bridge is uniquely identified by its Bridge ID, which comprises the bridge's root priority (a spanning tree parameter) followed by its MAC address.

For an overview of spanning tree operation see "Spanning tree operation" on page 18.2.

root path cost

A spanning tree property. Each port connecting a bridge to a LAN has an associated cost, called the root path cost. This is the sum of the costs for each path between the particular bridge port and the root bridge. The designated bridge for a LAN is the one that advertises the lowest root path cost. If two bridges on the same LAN have the same lowest root path cost, then the switch with the lowest bridge ID becomes the designated bridge.

For an overview of spanning tree operation see "Spanning tree operation" on page 18.2.

route-map

A mechanism for filtering IP routes and changing their attributes.

RSTP

Rapid Spanning Tree Protocol. RSTP is an evolution of the Spanning Tree Protocol (STP) which provides for faster spanning tree convergence after a topology change. A device running RSTP is compatible with other devices running STP.

For more information see "Rapid Spanning Tree Protocol (RSTP)" on page 18.8. For a configuration example see "Configuring RSTP" on page 18.9.

S

SCP

Secure Copy Protocol. SCP allows for secure file transfer to and from the switch, protecting your network from unwanted downloads and unauthorized file copying.

For more information see "Copying with Secure Copy (SCP)" on page 6.16.

script

A script is a sequence of commands stored as a plaintext file on a file subsystem accessible to the device, such as Flash memory. Each trigger may reference multiple scripts and any script may be used by any trigger. When an event activates a trigger, the trigger executes the scripts associated with it in sequence. One script is executed completely before the next script begins.

See Dynamic Link Failover.

SD card

Secure Digital card.

SDHC card

Secure Digital High Capacity card.

secondary port

In EPSR, a second ring port on the master node. This port remains active, but blocks all protected VLANs from operating unless the ring fails. Similar to the blocking port in an STP/RSTP instance.

For more information see "Ring Components and Operation" on page 81.2.

sFlow

sFlow®[1] is an industry standard technology for monitoring high speed switched networks. It provides the ability to monitor traffic in data networks containing switches and routers.

1. sFlow® is a registered trademark belonging to InMon Corp, San Francisco, CA.

For more information see Chapter 100, sFlow Introduction and Configuration. For how to configure sFlow see "Configuring sFlow on your Switch" on page 100.6.

sFlow agent

A network employing sFlow typically comprises a number of network (sFlow) agents that accumulate sampled data and traffic counter information. The agents then forward this data to a collector. The collector then analyses the information supplied by its agents in order to compile and display statistical profiles of the network and its traffic. The sFlow feature on your switch provides the sFlow agent capability.

For more information see "The sFlow Agent" on page 100.3.

sFlow collector

The sFlow collector receives traffic samples and counter information from a number of sFlow agents. These samples are received as a series of UDP datagrams. From the data contained within these datagrams, the collector is able to provide statistical and or graphical information of network traffic.

For more information see "The sFlow Collector" on page 100.5.

SFTP

SSH File Transfer Protocol. SFTP provides a secure way to copy files onto your device from a remote device.

For more information see "Copying with SSH File Transfer Protocol (SFTP)" on page 6.16.

software ACLs

See ACL types.

spanning tree

A loop free portion of a network topology. The network topology is dynamically pruned to provide only one path for any packet. See STP, RSTP and MSTP.

Spanning Tree Protocol Root Guard

See STP Root Guard.

SSH

Secure Shell. SSH is a network protocol that uses strong authentication and encryption for remote access across a nonsecure network. SSH provides sessions between a host running a SSH server and a machine with a SSH client.

For more information see Chapter 74, Secure Shell (SSH) Introduction. For how to configure a SSH server see "Configuring the SSH Server" on page 74.4. For how to configure a SSH client see "Configuring the SSH Client" on page 74.9.

stack

See VCStack.

Stack Master

The switch that manages the stack, or VCStack, also referred to as the Active Master.

See Disabled Master for information about how this relates to Stack Master or Active Master.

stack member

An individual switch that is part of a VCStack.

S-TAG

Service VLAN TAG.

static aggregator

See static channel group.

static channel group

A static channel group, also known as a static aggregator, enables a number of ports to be manually configured to form a single logical connection of higher bandwidth. By using static channel groups you increase channel reliability by distributing the data path over more than one physical link.

storm-control

Storm-control enables you to specify the threshold level for broadcasting, multicast, or destination lookup failure (DLF) traffic for a port. Storm-control limits the specified traffic type to the specified threshold.

For more information see "Storm-control" on page 14.16.

storm protection

Storm protection uses QoS mechanisms to classify on traffic likely to cause a packet storm (broadcast and multicast). With QoS storm protection, several actions are possible when a storm is detected:

- You can disable the port physically.
- You can disable the port logically.
- You can disable the port for a particular VLAN.

For more information see "Storm Protection" on page 60.33.

STP

Spanning Tree Protocol. STP is the original bridge protocol defined by IEEE standard 802.1D-1988. It creates a single spanning tree over a network.

For more information see "Spanning Tree Protocol (STP)" on page 18.5. For a configuration example see "Configuring STP" on page 18.6.

STP Root Guard

Spanning Tree Protocol Root Guard. STP Root Guard designates which devices can assume the role of root bridge in an STP network. This stops an undesirable device from taking over this role, where it could either compromise network performance or cause a security weakness.

See the spanning-tree guard root command on page 19.43.

subnet address

A subnet portion of an IP address. In a subnetted network, the host portion of an IP address is split into a subnet portion and a host portion using an address or subnet mask.

subnet mask

A bit mask used to select bits from an Internet address for subnet addressing. The mask is 32 bits long and selects the network portion of the Internet address and one or more bits of the local portion. Sometimes called address mask.

switch instance

A single switch chip with its associated ports, internal data interfaces, hardware tables, and packet buffer memory.

S-VID

Service VLAN ID.

S-VLAN

Service VLAN.

synchronous

Transmission in which the data characters and bits are transmitted at a fixed rate with the transmitter and receiver synchronized. This eliminates the need for start-stop elements, as in asynchronous transmission, but requires a flag character to be transmitted when there is no data to transmit. See “asynchronous” on page D.5

T

TACACS+

TACACS+ (Terminal Access Controller Access-Control System Plus) provides a method for securely managing multiple network access points from a single management service. TACACS+ is a TCP-based access control protocol that allows a device to forward a user's username and password to an authentication server to determine whether access can be allowed. In addition to this authentication service, TACACS+ can also provide authorization and accounting services. One of the features of TACACS+ is the ability to separate authentication, authorization and accounting so that these functions can be provided independently on separate servers.

For information on the AlliedWare Plus implementation of TACACS+, see Chapter 70, TACACS+ Introduction and Configuration and Chapter 71, TACACS+ Commands.

TCN

Topology Change Notification.

thrash limiting

MAC address thrashing occurs when MAC addresses move rapidly between one or more ports or trunks, for example, due to a network loop. Thrash limiting enables you to apply actions to a port when thrashing is detected. It is supported on all port types and also on aggregated ports.

For more information see "Thrash Limiting" on page 14.18

TLV

Type-Length-Value. A single LLDPDU contains multiple TLVs. TLVs are short information elements that communicate complex data, such as variable length strings, in a standardized format. Each TLV advertises a single type of information, such as its device ID, type, or management addresses. See LLDP advertisements.

traceroute

Traceroute is used to discover the route that packets pass between two systems running the IP protocol. Traceroute sends an initial UDP packets with the Time To Live (TTL) field in the IP header set starting at 1. The TTL field is increased by one for every subsequent packet sent until the destination is reached. Each hop along the path between two systems responds with a TTL exceeded packet (ICMP type 11) and from this the path is determined.

transit node

In EPSR, nodes other than the master node in the domain.

Transit node states are:

- Idle - the state when EPSR is first configured, before the master node determines that all links in the ring are up. In this state, both ports on the node are blocked for the data VLAN. From this state, the node can move to Links Up or Links Down.
- Links Up - the state when both the node's ring ports are up and forwarding. From this state, the node can move to Links Down.
- Links Down - the state when one or both of the node's ring ports are down. From this state, the node can move to Preforwarding.
- Pre-forwarding - the state when both ring ports are up, but one has only just come up and is still blocked to prevent loops. From this state, the transit node can move to Links Up if the master node blocks its secondary port, or to Links Down if another port goes down.

For more information see "Ring Components and Operation" on page 81.2.

tri-authentication

Authentication commands enable you to specify three different types of device authentication: 802.1X authentication, MAC authentication, and Web-authentication. All three types can be configured to run simultaneously on a switch port. The simultaneous configuration and authentication of all three types on a port is called tri-authentication.

For a configuration example see "Tri-Authentication Configuration" on page 64.2.

trigger

A trigger is an ordered sequence of scripts that is executed when a certain event occurs. Each trigger may reference multiple scripts and any script may be used by any trigger. When an event activates a trigger, the trigger executes the scripts associated with it in sequence. One script is executed completely before the next script begins.

See Dynamic Link Failover.

Type-Length-Value

See TLV.

U

unicast

Two individual devices hold a conversation just between themselves.

V

VCStack

A group of two or more switches operating as a single switch. See Virtual Chassis Stacking.

VCStack Fast Failover

VCStack Fast Failover provides absolutely minimal network downtime in the event of a problem with the stack.

See the reboot rolling command on page 103.7.

VID

VLAN Identifier or VLAN ID. When you create a VLAN you give it a numerical VID which is included in VLAN-tagged Ethernet frames to and from this VLAN.

Virtual Chassis Stacking

Virtual Chassis Stacking (VCStack™) is the name given to two or more Allied Telesis switches that are configured to operate as a single switch. From a configuration and management point of view, it is as though the switches are just one device with a seamless transition from the ports of one stack member to the ports of the next.

For more information see Chapter 102, Stacking Introduction.

VLAN classification

A packet can be allocated VLAN membership based on its protocol, subnet, or port.

VLAN double tagging

VLAN double tagging is used operate a number of private Layer 2 networks within a single public Layer 2 network. A VLAN double tagging implementation consists of the following port types:

- Provider ports - these connect to a service provider's Layer 2 network
- Customer edge ports - these connect to a customer's private Layer 2 network

For more information see "VLAN Double Tagging (VLAN Stacking)" on page 16.5. For a configuration example see "Configuring double-tagged VLANs" on page 16.6.

VLAN ID

See VID.

VLAN Identifier

See VID.

VLAN stacking

See VLAN double tagging.

VLAN tag

IEEE standard 802.1q defines an additional 4 byte tag field that can be inserted immediately following the MAC address, plus any routing fields present. This field contains a 12 bit VLAN identifier, commonly referred to as the VLAN tag. The VLAN tag is used to determine which VLAN a given frame should be forwarded to.

Other tags included in the 802.1q tag field is a Tag Protocol Identifier tag, and a Type of Service tag used to determine data priority.

Voice VLAN

Voice VLAN automatically separates voice and data traffic into two different VLANS. This automatic separation places delay-sensitive traffic into a voice-dedicated VLAN, which simplifies QoS configurations.

For more information see "Voice VLAN" on page 90.3.

VoIP

Voice over Internet Protocol. Enables the delivery of voice communications over IP networks such as the Internet or other packet-switched networks instead of over traditional telephony circuits.

VRF

Virtual Routing and Forwarding. VRF is used with the VRF-Lite feature, where multiple routing and forwarding instances can separately reside within a single x900 series switch.

VRF-Lite

Virtual Routing and Forwarding Lite (VRF-Lite) provides a cut back (lightweight) version of the full VRF capability that is used to create large-scale Virtual Private Networks (VPNs). VRF-Lite enables a global routing domain and eight separate VRF routing instances to reside within a single x900 series switch.

VPN

Virtual Private Network (VPN) is a private customer network that exists as part of a larger public or private network infrastructure. Each customer network can operate as a totally isolated entity within the network suppliers infrastructure that operates to its own management policies and rules.

VRID

Virtual Router Identifier.

VRRP

Virtual Router Redundancy Protocol. VRRP combines two or more physical switches into a logical grouping called a virtual router. The physical switches then operate together to provide a single logical gateway for hosts on the LAN. If the master fails, the other devices assume the virtual IP address.

For more information see Chapter 79, VRRP Introduction and Configuration. For configuration examples see “Configuration examples” on page 79.9.

W

Web-authentication

The switch sends a login screen to the client webbrowser which must be authenticated before access is granted to the network. See AAA and tri-authentication.

For a sample configuration script see “Sample Web-Authentication Configuration” on page 66.9.

wildcard mask

A subnet mask in which bits set to 0 indicate an exact match and bits set to 1 indicate ‘don’t care’.

X

XEM

High Speed Expansion Module.
